

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

NOW COMPLETE.

Imperial Folio, bound in cloth, £2 10s., or half morocco, £2 17s.

ON DISLOCATIONS & FRACTURES.

By JOSEPH MACLISE, F.R.C.S.

Subscribers are requested to complete their Sets early, to prevent disappointment in obtaining the Numbers wanted.

By the same Author,

SURGICAL ANATOMY.

A SERIES OF DISSECTIONS, ILLUSTRATING THE PRINCIPAL REGIONS OF THE HUMAN BODY.

The Second Edition, cloth, £3 12s.; or bound in morocco, £4 4s.

John Churchill, New Burlington-street.

Just published, 8vo, cloth, price 9s.

A Treatise on Vital Causes.

By JAMES NEWTON HEALE, M.D. Lond., Physician to the Hants County Hospital.

John Churchill, New Burlington-street.

Fcap. 8vo, cloth, 5s.

Practical Observations on Gout and

ITS COMPLICATIONS, and on the TREATMENT OF JOINTS STIFFENED BY GOUTY DEPOSITS. By T. SPENCER WELLS, F.R.C.S. Lecturer on Surgery at the Grosvenor-place School.

"Contains many useful hints respecting diagnosis and treatment in the complicated and latent forms of gout especially."—*Dublin Medical Press.*
"Contains much that is new, and more that is useful. The principles of treatment laid down are the result of experience, guided and applied by correct physiological views."—*Dublin Quarterly Journal of Medical Science.*

John Churchill, New Burlington-street.

Post 8vo, cloth, 3s. 6d.

Davies's (Dr. Henry) Young Wife's

GUIDE DURING PREGNANCY and CHILDBIRTH, and in the MANAGEMENT OF HER INFANT.

Post 8vo, cloth, 5s.

HAND-BOOK of DOMESTIC MEDICINE; popularly arranged. By an EMINENT PHYSICIAN. 700 pages, with a complete Index.

* * FOR OTHER MEDICAL WORKS SEE PAGE 5.

Henry G. Bohn, York-street, Covent-garden, W.C.

VOL. XL. No. 1031.—NEW SERIES, No. 470.

Just published, in 8vo, pp. 430, price 10s. 6.

Lectures on Pathological Anatomy,

with accompanying Tables, being a systematic treatise on the subject, and a complete Manual for Students. By SAMUEL WILKS, M.D. Lond., Fellow of the Royal College of Physicians, Assistant-Physician to Guy's Hospital, Lecturer on Pathology, and Curator of the Museum.

London: Longman, Brown, and Co., Paternoster-row.

On the First of July, Vol. XXIX. post 8vo, cloth, 6s. 6d.

Half-Yearly Abstract of the Medical

SCIENCES; being a Practical and Analytical Digest of the Contents of the principal British and Continental Medical Works published in the preceding Half-year; together with a Critical Report of the Progress of Medicine and the Collateral Sciences during the same period.

Edited Dr. RANKING and Dr. RADCLIFFE.

John Churchill, New Burlington-street.

Just published, 8vo, cloth, 12s.

Illustrated by 17 Coloured Figures and 41 Woodcuts,

On Wounds and Injuries of the Eye.

By W. WHITE COOPER, F.R.C.S., Surgeon Oculist in Ordinary to Her Majesty, Ophthalmic Surgeon to St. Mary's Hospital, &c.

"A book of very practical character, and one that contains a large amount of information on a subject upon which hitherto we have possessed no English monograph. The volume is profusely and elegantly illustrated, and bids fair to become a favourite with the Profession."—*Med.-Chir. Rev.*

John Churchill, New Burlington-street.

Just published, a new edition (the 3rd), pp. 1005, with Five Hundred Illustrations on Wood, price 30s.

Clinical Lectures on the Principles

and PRACTICE OF MEDICINE. By J. HUGHES BENNETT, M.D. F.R.S.E. Professor of the Institutes of Medicine, and Senior Professor of Clinical Medicine in the University of Edinburgh.

By the same Author, in 12mo, the Third Edition, price 5s.

AN INTRODUCTION TO CLINICAL MEDICINE: Six Lectures on the Method of examining Patients, and the Means Necessary for Arriving at an exact Diagnosis.

"As a concise and eminently clear exposition of one branch of the art of Medicine, it is invaluable to the student and junior practitioner. The chapter on Skin Diseases we consider a triumph in its way. In conclusion, we desire to recommend this lucid exposition of the art of diagnosis to our junior readers, well assured that they will find no better or more condensed information on the subject in any book in the English language."—*Lancet.*

In 12mo, profusely illustrated, price 6s.

OUTLINES of PHYSIOLOGY.

"Whether as an Introduction to physiological science, or as a summary of Dr. Bennett's doctrines, this treatise will act powerfully in diffusing a knowledge of scientific medicine, and will prove, we doubt not, highly acceptable to Medical Students and Practitioners."—*Edinburgh Medical Journal.*

Edinburgh: Adam and Charles Black; London: Longman and Co.

On the 1st of July, No. XLVII. price Six Shillings, of
**The British and Foreign Medico-
CHIRURGICAL REVIEW.**

ANALYTICAL AND CRITICAL REVIEWS.

1. Brown-Séguard on the Nervous System.
2. Statistical Report of the Royal Navy.

LOCALISED MOVEMENTS; or, Medical Gymnastics.

BY HENRY HEATHER BIGG,
Anatomical Mechanist to the Queen.

These works, which are especially dedicated to the Medical Profession, are intended to illustrate the various mechanical appliances employed for loss of limb, spinal curvature, club-foot, and every variety of bodily distortion.

John Churchill, New Burlington-street.

WORKS BY WHARTON JONES, F.R.S.

Professor of Ophthalmic Surgery and Medicine, University College Hospital.

I.

**A Manual of the Principles and
PRACTICE of OPHTHALMIC MEDICINE and Surgery.** Illustrated by Engravings, plain and coloured. Second Edition. Foolscape 8vo, cloth, 12s. 6d.

II.

The Wisdom and Beneficence of the

ALMIGHTY, as DISPLAYED in the SENSE of VISION: being the Aetonian Prize Essay. With Illustrations on Steel and Wood. Foolscape 8vo, cloth, 4s. 6d.

III.

Defects of Sight: their Nature, Causes,

Prevention, and General Management. Foolscape 8vo, 2s. 6d.

IV.

A Catechism of the Medicine and

SURGERY of the EYE and EAR. For the Clinical Use of Hospital Students. Foolscape 8vo, 2s. 6d.

V.

A Catechism of the Physiology and

PHILOSOPHY of BODY, SENSE, and MIND. For Use in Schools and Colleges. Foolscape 8vo, 2s. 6d.

John Churchill, New Burlington-street.

CHURCHILL'S MANUALS.

Foolscape octavo, cloth, price 12s. 6d. each Volume.

Aggregate Sale, 105,000 Copies.

Anatomy—Mr. ERASMUS WILSON.

Chemistry—Mr. FOWNES.

Dental Surgery—Mr. TOMES.

Materia Medica—Dr. ROYLE and Dr. HEADLAND.

Medicine—Dr. BARLOW.

Medical Jurisprudence—Dr. TAYLOR.

Microscope—Dr. CARPENTER.

Natural Philosophy—Dr. G. BIRD and Mr. BROOKE.

Obstetrics—Dr. TYLER SMITH.

Ophthalmic Medicine—Mr. WHARTON JONES.

Pathological Anatomy—Dr. H. JONES and Dr. SIEVEKING.

Physiology—Dr. CARPENTER.

Poisons—Dr. TAYLOR.

Surgery—Mr. FERGUSSON.

JOHN CHURCHILL, New Burlington-street.

NEW WORKS BY LIONEL BEALE, M.B. F.R.S.

Just published, 8vo, 14s.

**The Microscope in its Application
TO PRACTICAL MEDICINE.** 270 Woodcuts.

5s.
HOW TO WORK WITH THE MICROSCOPE. A Guide to the Practical Use of the Instrument, with Directions for Examining and Preserving Specimens, Injecting, &c.

8vo, 9s. 6d.

ILLUSTRATIONS OF URINE, URINARY DEPOSITS, AND CALCULI. 35 Plates, containing upwards of 170 separate figures carefully copied from the objects. This work is intended specially for the assistance of the Medical Practitioner in the examination of the Urine.

The ANATOMY of the LIVER. 66 Photographs. 8vo, 6s. 6d. Only a few copies of the Photographs remain, and no more will be printed.

TABLES for the PRACTICAL, CHEMICAL, and MICROSCOPICAL EXAMINATION of URINE, URINARY DEPOSITS, and CALCULI. 2s. 6d.

ON URINE, URINARY DEPOSITS, AND CALCULI. [Preparing.]

Annual Subscription, 7s.

ARCHIVES OF MEDICINE. Edited by Dr. BEALE. No. IV. nearly ready.

Vol. I. price 15s. bound in cloth, 31 Plates, numerous Woodcuts, will be published shortly.

John Churchill, New Burlington-street.

On Poisons, in Relation to Medical

JURISPRUDENCE and MEDICINE.

Second Edition, fcap. 8vo, cloth, 12s. 6d.

By ALFRED S. TAYLOR, M.D., F.R.S.

By the same Author,

A MANUAL OF MEDICAL JURISPRUDENCE.

Sixth Edition, fcap. 8vo, cloth, 12s. 6d.

"We can bear testimony to the care with which the revision of this new edition has been conducted. There is hardly a page which does not bear evidence of rigid scrutiny, and of the addition of the latest facts and observations."—Edinburgh Medical Journal.

John Churchill, New Burlington-street.

Just published, 8vo, cloth, 12s. 6d.

Demonstrations of Diseases in the

CHEST, AND THEIR PHYSICAL DIAGNOSIS. By HORACE DOBELL, M.D., Physician to the Royal Infirmary for Diseases of the Chest. Illustrated with coloured Plates of all the principal Diseases of the Lungs and Pleura. Each plate accompanied by a concise statement of the Physical Signs to be observed during Life, and followed by a corollary upon its leading points.

"We do not hesitate to say, that the student who, after the examination of a patient, refers to this book, will have a much greater facility in understanding the rationale of the phenomena and of interpreting them correctly, than one who is satisfied with comparing what he hears to the descriptions of sounds given in handbooks, or to some typical sound pointed out to him by his teacher. . . . What the author gives is well done, and in the right direction."—Brit. and For. Med.-Chir. Rev.

"The present work will form a valuable addition to the existing literature on the subject. . . . The plates are taken from fresh specimens of disease, and are very well executed, the colouring of the engravings heightening their effect, and giving them all the appearance of reality."—Medical Times and Gazette.

John Churchill, New Burlington-street.

Just published, Sixth Edition, foolscap 8vo, 2s. 6d.

Healthy Skin; a Popular Treatise on

the Skin and Hair, their Preservation and Management.

By ERASMUS WILSON, F.R.S.

John Churchill, New Burlington-street.

Just published, 8vo, 1s.; by post 1s. 1d.

On the Prevention of Consumption by

the USE of the HYPOPHOSPHITES.

By J. FRANCIS CHURCHILL, M.D.

John Churchill, New Burlington-street.

Just published, 8vo, 2s. 6d.

Hemorrhoids and Prolapsus of the

RECTUM: their Treatment by the Application of Nitric Acid. By HENRY SMITH, F.R.C.S. Surgeon to the Westminster General Dispensary.

John Churchill, New Burlington-street.

Just published, Third Edition, 8vo, cloth, 6s.

An Inquiry into the Curability of

CONSUMPTION, its PREVENTION, and the PROGRESS of IMPROVEMENT in the TREATMENT. By JAMES TURNBULL, M.D. Physician to the Liverpool Royal Infirmary.

This New Edition embraces the substance of the author's two previous works on Consumption, together with much new matter on the Causes, Prevention, and Treatment.

John Churchill, New Burlington-street.

Just published, Third Edition, 8vo, cloth, 12s. 6d.

On the Action of Medicines in the

SYSTEM. By FREDERICK W. HEADLAND, M.D., L.R.C.P.

"Such a treatise as Dr. Headland's doubtless was wanted, and the vacancy has been filled by this gentleman in a manner which is as creditable to the scientific medicine of this country as it is honourable to himself."—*Lancet*."The Author's remarks all through this book appear to us sensible and to the point, and the entire work must command the most attentive consideration of the reader."—*Dublin Medical Press*.

John Churchill, New Burlington-street.

Illustrated with 186 Engravings, fcap. 8vo, cloth, 12s. 6d.

A Manual of Obstetrics.

By W. TYLER SMITH, M.D., Lecturer on Midwifery at St. Mary's Hospital.

"A systematic Treatise on Obstetrics has long been wanting for Mr. Churchill's series of Manuals, and this work will be the favourite and honoured guide of the English Student of Midwifery."—*Lancet*."This Manual is profusely illustrated with woodcuts, is carefully written, compact, and admirably adapted for students."—*Edinburgh Medical Journal*.

John Churchill, New Burlington-street.

Second Edition, 18mo, cloth, 6s.

The Book of 3000 Prescriptions.

Collected from the Practice of the most eminent Physicians and Surgeons, English and Foreign. By HENRY BEASLEY.

"This is really a most useful and important publication, and, from the great aid which it is capable of affording in prescribing, it should be in the possession of every Medical practitioner. Among other advantages is that, by giving the prescriptions of some of the most able and successful practitioners of the day, it affords an insight into the methods of treatment pursued by them, and of the remedies which they chiefly employed in the treatment of different diseases."—*The Lancet*.

John Churchill, New Burlington-street.

By ROBERT LEE, M.D., F.R.S.

Clinical Midwifery: comprising the

Histories of 545 Cases of Difficult, Prematural, and Complicated Labour, with Commentaries. Second Edition, fcp. 8vo, cloth, 5s.

"More instructive to the juvenile practitioner than a score of systematic works."—*The Lancet*."Will be consulted by every accoucheur who practises his art with the zeal which it merits."—*Medical Times and Gazette*."A storehouse of valuable facts and precedents."—*American Journal of the Medical Sciences*.

II.

ON OVARIAN and UTERINE DISEASES. Foolscap 8vo, cloth, 6s. 6d."The cases related amount to about five hundred; they constitute, we hesitate not to say, the most valuable and extensive collection of clinical facts that has yet been published in this department of medicine."—*Dublin Medical Press*.

III.

ON the EMPLOYMENT of the SPECULUM in the DIAGNOSIS and TREATMENT of UTERINE DISEASES. With 300 Cases. 8vo, cloth, 4s. 6d.

IV.

PRACTICAL OBSERVATIONS on DISEASES of the UTERUS. With Coloured Plates. Two Parts. Imperial 4to, 7s. 6d. each Part.

John Churchill, New Burlington-street.

LEWIS'S MEDICAL LIBRARY,

15, GOWER-STREET NORTH.

ALL the NEW BOOKS and MOST RECENT EDITIONS are IMMEDIATELY ACCESSIBLE to every Member of the Medical Profession throughout the country, and are exchangeable, often or seldom, at the pleasure of subscribers.

The following are a few of the recent additions, and indicate the range of subjects which this Library embraces:—

Bennett's Clinical Lectures. Third Edition.
 Craig's Electric Tension and Epidemics.
 Althaus's Medical Electricity.
 Hamilton's Metaphysical Lectures. 2 vols.
 Bucknill's Psychology of Shakespeare.
 Schimmelpenninck's Principles of Beauty and Temperaments.
 Powell (Baden) Order of Nature.
 Boismont on Hallucinations, by Hulme.
 Medical and Surgical History of the British Army in Turkey and the Crimea.
 White Cooper's Wounds and Injuries of the Eye.
 Dixon on the Eye. New Edition.
 Tomes's Dental Surgery.
 Gray's Anatomy.
 Humphrey's Skeleton.
 Bain's Emotions and the Will.
 Miller's Sketches of Geology.
 Parkin's Causation and Prevention of Disease.
 Fraser's Penetrating Wounds of the Chest.
 Wardrop's Diseases of the Heart. New Edition.
 Balfour's Botany and Religion.
 Adams's Rheumatic Gout.
 Sir Humphrey Davy's Remains.
 Ricord on Chancre, by Maumder.
 Sanger's History of Prostitution.
 Thudichum's Pathology of the Urine.
 Jones's Aquarium Naturalist.
 Gosse's Evenings with the Microscope.
 Brinton's Diseases of the Stomach.
 Latham's Descriptive Ethnology. 2 vols.
 Dun's Veterinary Medicines.
 West's Diseases of Women.
 Johnston and Sinclair's Midwifery.
 Snow's Anæsthetics, by Richardson.
 Richardson's Coagulation of the Blood.
 Headland's Action of Medicines.
 Basham on Dropsy.
 Thompson's Stricture of the Urethra. New Edition.
 Beale's Microscope and Clinical Medicine.
 Roberts' Wasting Palsy.
 Bucknill and Tulke's Psychological Medicine.
 Dobell's Diseases of the Chest.

Just published, fcap. 8vo, cloth, 12s. 6d.

A System of Dental Surgery

Illustrated with 208 Engravings in Wood.

By JOHN TOMES, F.R.S.

Mr. Churchill is happy to announce this additional Volume to his Series of Manuals. The scientific reputation of the Author, the practical character of the work, and the 208 Engravings, executed in Mr. Bagg's best style, must constitute it the book of reference to all practising the art of Dentistry.

John Churchill, New Burlington-street.

Third Edition, fcap. 8vo, cloth, 12s. 6d.

A Manual of Materia Medica and THERAPEUTICS.

By J. FORBES ROYLE, M.D., F.R.S., and F. W. HEADLAND, M.D.

"The style and method of Dr. Royle are all that could be desired in an elementary work. The wood engravings, by which the different crystals, the various parts of the vegetable products, and the medicinal animals, are illustrated, are better than anything hitherto attempted in this department of Materia Medica, and must prove a great assistance to the student, appealing as they do more powerfully to the mind than the most careful verbal descriptions taken alone could do."—Lancet.

John Churchill, New Burlington-street.

Just published, 8vo, cloth, 5s.

On the Operations for Strangulated

HERNIA. By J. H. JAMES, F.R.C.S., Consulting Surgeon to, and late Senior Surgeon of, the Devon and Exeter Hospital.

"Even on so well-worn a subject as Hernia, Mr. James has found the art of saying something original, and at the same time valuable. We can heartily commend his book to our readers, and hope that his example in turning a long experience to account may be extensively followed by our 'practical Surgeons.'"—Med. Chir. Review.

"Mr. James has made a valuable addition to those contributions to surgical knowledge, which have long ago made his name honourably known in his Profession."—British Medical Journal.

John Churchill, New Burlington-street.

Just published, Second Edition, revised, with considerable Additions, post 8vo, cloth, 9s.

A Guide to the Practical Study of

DISEASES of the EYE. By JAMES DIXON, Surgeon to the Royal London Ophthalmic Hospital.

"This second edition is both enlarged and improved, and we can recommend the work to be really what it professes—A Guide—and a very useful and trustworthy guide—to the Practical Study of Diseases of the Eye."

John Churchill, New Burlington-street.

Third Edition, 8vo, cloth, 15s.

Principles of Medicine.

By C. J. B. WILLIAMS, M.D., F.R.S.

"The well-known and highly-esteemed work of Dr. Williams appears in its present form very considerably enlarged, and revised throughout. The most recent investigations in physiology and animal chemistry have been laid under contribution."—Medical Times and Gazette.

"We hail this work, and recommend it for a text book, guide, and constant companion to every practitioner and every student who wishes to extricate himself from the well-worn ruts of empiricism, and to base his practice of medicine upon principles."—The Lancet.

John Churchill, New Burlington-street.

Fcap. 8vo, cloth, 12s. 6d.

A Manual of the Practice of Medicine.

By G. H. BARLOW, M.D., Physician to Guy's Hospital.

"We recommend Dr. Barlow's Manual in the warmest manner. We have had frequent occasion to consult it, and have found it clear, concise, practical, and sound. It is eminently a practical work, containing all that is essential, and avoiding useless theoretical discussion. The work supplies what has been for some time wanting, a manual of practice based upon modern discoveries in pathology and rational views of treatment of disease. It is especially intended for the use of students and junior practitioners, but it will be found hardly less useful to the experienced physician."—Boston Med. Journal.

"The Student has long been in want of a good elementary work on the Practice of Medicine. In Dr. Barlow's Manual that want is supplied; and we have no question that it will at once be installed as the favourite textbook in all medical schools."—Med Times and Gaz.

John Churchill, New Burlington-street.

With Fifty Engravings on Wood. Post 8vo, cloth, 6s. 6d.

A Manual of Photographic

MANIPULATION: Treating of the Practice of the Art in its various Applications to Nature. By LAKE PRICE, Photographer of the Royal Portraits taken at Windsor.

"The Author of this Manual is well known as one of the most successful of the cultivators of the art of photography. With full artistic feeling, it has been his aim to give a higher character to the sun-drawn picture than that which ordinarily belongs to a process essentially mechanical in all its details. . . . We have gone through the book with much care, and we believe there is not a point omitted which it was necessary to explain to the amateur. . . . Mr. Lake Price writes with the enthusiasm of a master, loving the art of his adoption; and many portions of his book may be read with pleasure, while the whole will be studied with unmistakeable advantage."—Athenæum.

John Churchill, New Burlington-street.

Fifth Edition, with considerable Additions, fcap. 8vo, cloth, 7s. 6d.

A Manual of Photographic Chemistry,

including the Practice of the Collodion Process. By T. FREDERICK HARDWICH, Lecturer on Photography at King's College.

John Churchill, New Burlington-street.

Second Edition, 8vo, cloth, 5s.

Pathology and Treatment of Stricture

of the URETHRA. By JOHN HARRISON, F.R.C.S.

John Churchill, New Burlington-street.

Fifth Edition, 8vo, cloth, 10s. 6d.

On the Diseases of the Bladder and

PROSTATE GLAND. By WILLIAM COULSON, Surgeon to, and Lecturer on Surgery at, St. Mary's Hospital.

By the same Author.

With numerous Engravings on Wood, 8vo, cloth, 8s.

ON LITHOTRITY AND LITHOTOMY.

John Churchill, New Burlington-street.

Just published, Second Edition, revised and enlarged, post 8vo, cloth, 7s. 6d.

Epilepsy, and other Convulsive

AFFECTIONS; their Pathology and Treatment. By CHARLES BLAND RADCLIFFE, M.D., F.R.C.P., Physician to the Westminster Hospital.

"The work before us (which must be regarded as a new book rather than as a second edition) goes far to establish the necessity for a radical change in the pathology and treatment of epilepsy and convulsive affections generally."—Medical Times and Gazette.

"Amongst those who at the present moment have entered on the new race of medical science, the author of the book before us stands in a forward place—a very accomplished man clearly, a man of deep thought, and, what is better than all, a man entirely earnest in his own business. . . . We have read it from the first to the last page with so much pleasure that we envy the man who has not read it, the treat he has in store."—Lancet.

John Churchill, New Burlington-street.

Just published, Second Edition, fcap. 8vo, cloth, 8s. 6d.

A Manual of Medical Diagnosis. By

A. W. BARCLAY, M.D., F.R.C.P., Assistant-Physician to St. George's Hospital.

"Dr. Barclay has carefully systematised the results of his observation of over twelve thousand patients, and by his diligence and judicious classification, the profession has been presented with the most convenient and reliable work on Diagnosis that it has been our good fortune ever to examine; we can say that it is one of the best works 'for reference' in the daily emergencies of the practitioner, with which we are acquainted."—American Medical and Surgical Journal.

"We venture to predict that the work will be deservedly popular, and soon become, like Watson's Practice, an indispensable necessity to the practitioner."—North American Medical Journal.

"We hope the volume will have an extensive circulation, not among students of medicine only, but practitioners also. They will never regret a faithful study of its pages."—Cincinnati Lancet.

John Churchill, New Burlington-street.

Just published, post 8vo, 7s. 6d. cloth,

On Epilepsy and Epileptiform

SEIZURES; their Causes, Pathology and Treatment. By EDWARD H. SIEVEKING, M.D., Physician to, and Lecturer upon Materia Medica at, St. Mary's Hospital.

"We have perused this volume with unfeigned pleasure, and have completed our task with a feeling of increased respect for its able and accomplished Author."—Edin. Med. Journal.

"The above is a brief and imperfect outline of the chief subjects discussed in Dr. Sieveking's able work, which we recommend to the Profession as containing a great amount of valuable information."—Med. Times and Gaz.

"Dr. Sieveking's work should be read and carefully studied by every Physician practising, for of late years there have been few more valuable contributions to practical medicine in aiding our knowledge of a most obscure disease."—Dublin Quar. Jour.

John Churchill, New Burlington street.

Fourth Edition, with Additions, cloth, 22s.

The Principles and Practice of

OBSTETRIC MEDICINE AND SURGERY. Illustrated with 120 Plates on Steel and Wood. By F. H. RAMSBOTHAM, M.D.

"It is THE book of Midwifery for students—clear, and sound in its practical instructions."—Dublin Jour. of Med. Science.

"The work of Dr. Ramsbotham may be described as a complete system of the principles and practice of midwifery. The illustrations are numerous, well selected, and appropriate, and engraved with great accuracy and ability. We regard this work as by far the most able work on the principles and practice of midwifery that has appeared for a long time."—Edin. Med. and Surg. Jour.

"Dr. Ramsbotham has treated the subject in a manner worthy of the reputation he possesses, and has succeeded in forming a book of reference for practitioners and a solid and easy guide for students."—British Med. Jour.

"This is one of the most beautiful works which have issued from the medical press, and is alike creditable to the talents of the author and the enterprise of the publisher. It is a good and thoroughly practical treatise."—Edin. Jour. of Med. Science.

John Churchill, New Burlington-street.

On the 1st of July, No. XV. New Series, price 3s. 6d.
The Journal of Psychological Medicine.
 Edited by FORBES WINSLOW, M.D., D.C.L. Oxon.

CONTENTS.

Psychological Quarterly Retrospect.
 Sir William Hamilton's Lectures on Metaphysics.
 Pauper Lunacy.
 Principles of Early Mental Education.
 Proposed Legislation in Lunacy.
 Dante: a Psychological Study.
 Law of Lunacy and the Condition of the Insane in Scotland.
 Medico-Legal Trial—Disputed Will—Plea of Unsound Mind.
 Sussex Lunatic Asylum.
 Case of Mr. Ruck.

John Churchill, New Burlington-street.

Just published, post 8vo, cloth, 4s. 6d.
The Irritable Bladder; its Causes and
 Curative Treatment. By FREDERICK JAMES GANT, M.R.C.S.
 Surgeon to the Royal Free Hospital.

John Churchill, New Burlington-street.

Just published, 8vo, cloth, 5s.
The Causation and Prevention of
 DISEASE. With an Appendix, showing that the Sewage of Towns
 may be employed as a Manure, without any risk or injury to the health.
 By JOHN FARKIN, M.D.

John Churchill, New Burlington-street.

Just published, 8vo, price 2s.
On the Treatment of the Epidemic
 Cholera: a Memoir read before the Members of the French
 Academy of Sciences, with their Report thereon. By JOSEPH AYRE, M.D.
 many years Physician to the General Hospital, Hull.

John Churchill, New Burlington-street.

Just published, Third Edition, price 3s. 6d.
The Treatment of Ulcers and Cutaneous
 ERUPTIONS on the LEG without Confinement.
 By HENRY T. CHAPMAN, F.R.C.S. &c.
 "Will well repay perusal."—Ranking's Abstract, Vol. xvii.
 Also, by the same Author, price 3s. 6d.
VARICOSE VEINS AND THEIR TREATMENT.

John Churchill, New Burlington-street.

Just published, Second Edition, 8vo, cloth, 16s.
Lectures on the Diseases of Women.
 By CHARLES WEST, M.D., Physician-Accoucheur to St. Bar-
 tholomew's Hospital.

"As a sound practical treatise, based on the extended experience of a
 close and accurate observer, whose views and acquirements are quite *au
 niveau* with the present state of medico-obstetrical science, this work is
 fairly entitled to the highest rank; and as such, we strongly and heartily
 commend it to the attention of our professional brethren."—Dublin Quar.
 Jour. of Med. Science.

"We have derived much pleasure and profit in the perusal of Dr. West's
 work; the way in which the subject is treated is lucid and full."—The
 Lancet.

John Churchill, New Burlington-street.

Just published, with Coloured Plates, 8vo, cloth, 14s.
A Treatise on the Pathology of the
 URINE, including a complete Guide to its Analysis. By J. L. W.
 THUDICHUM, M.D. Lecturer on Chemistry at the Grosvenor-place School
 of Medicine.

"To the student and practitioner alike the Treatise is invaluable. It
 ranks from the first a standard work, every chapter of which indicates
 that its author has observantly studied his subjects in their practical
 bearings."—Med. Times and Gaz.

"This is a book which must gain a high reputation for the author. The
 plates, which are beautifully executed, are for the most part excellent re-
 presentations of the various substances found in urine; and we thank
 him for the highly valuable treatise which he has offered to all scientific
 and truly practical Physicians."—Brit. Med. Jour.

John Churchill, New Burlington-street.

8vo, cloth, with a 4to Atlas of Plates, 21s.
A Treatise on Rheumatic Gout, or
 CHRONIC RHEUMATIC ARTERITIS on all the ARTICULATIONS.
 By ROBERT ADAMS, A.M., M.D., M.R.I.A., Ex-President of the Patho-
 logical Society of Dublin.

"We have only to add the most unqualified approbation of the work. It
 must be regarded not only as most creditable to the author, maintaining
 and enhancing his high reputation and that of the Dublin school, but as
 a real acquisition to the medical literature of the age."—Medical Times
 and Gazette.

"There accompanies the work a large atlas of lithographic drawings,
 beautiful specimens of art, which enhance in no small degree the value of
 this great literary labour."—Dublin Medical Journal.

"The monograph of Dr. Adams, with its illustrative atlas, is the result
 of clinical and pathological investigations continued through many years.
 As a record of facts observed with regard to rheumatic gout, Dr.
 Adams's work forms a most valuable contribution to our knowledge."—
 British Medical Journal.

John Churchill, New Burlington-street.

MEDICAL BOOKS

Published or Sold by

HENRY G. BOHN.

**Bateman and Willan's Delineations of Cuta-
 NEOUS DISEASES.** 72 plates, carefully coloured under the superin-
 tendence of an eminent Surgeon, 4to, half-bound morocco (published
 at £12 12s.)—£5 5s.

Bateman and Willan's Practical Synopsis of
 CUTANEOUS DISEASES, exhibiting a concise View of the Diagnostic
 Symptoms and the Method of Treatment. Eighth Edition, edited by
 Dr. A. T. THOMSON, with coloured plate, 8vo, cloth (published at 15s.)
 —7s. 6d.

Bateman's Atlas of Delineations of Cutaneous
 ERUPTIONS, by A. T. THOMSON. Royal 8vo, 27 coloured plates,
 10th lettered (published at £3 3s.)—£1 16s.

Bolley's Manual of Technical Analysis; a
 Guide for the Testing and Valuation of the various Natural and Artificial
 Substances employed in the Arts and in Domestic Economy. Translated
 from the German with considerable additions, by B. H. PAUL, Ph.D.,
 F.C.S., with nearly 100 wood engravings. Post 8vo, cloth, 5s.

Liston's Elements of Surgery. Second Edition,
 thick 8vo, with engravings on wood and steel, cloth (published at £1 5s.)
 —reduced to 10s. 6d.

Prout's Bridgewater Treatise on Chemistry,
 METEOROLOGY, AND THE FUNCTION OF DIGESTION. Fourth
 Edition, edited by Dr. J. W. GRIFFITH, with coloured Maps. Post 8vo,
 cloth, 5s.

Laennec on the Diseases of the Chest, and on
 Mediate Auscultation; translated, with Notes, by Dr. FORBES. Fourth
 Edition, enlarged, with plates, 8vo, cloth (published at 18s.)—reduced
 to 9s.

Thompson's (Dr. A. T.) Elements of Materia
 MEDICA AND THERAPEUTICS; including the Recent Discoveries, and
 Analysis of Medicines. New edition, enlarged and improved, 8vo,
 (1400 pp.) with upwards of 100 fine wood engravings, cloth (published at
 £1 11s. 6d.)—12s.

Burn's Principles of Midwifery, tenth and
 best edition, thick 8vo, cloth lettered (published at 16s.)—5s.

Liston's Elements of Surgery. Second Edition,
 thick 8vo, with engravings on wood and steel, cloth (published at £1 5s.)
 —10s. 6d.

**Stockhardt's Agricultural Chemistry, or Che-
 MICAL FIELD LECTURES;** a familiar Exposition of the Chemistry of
 Agriculture, addressed to Farmers; translated from the German, with
 Notes by PROFESSOR HENFREY, of King's College. To which is
 added, a Paper on LIQUID MANURE, by J. J. MECHI, Esq. Post 8vo,
 cloth, 5s.

Carpenter's Zoology; a Systematic View of the
 Structure, Habits, Instincts, and Uses, of the principal Families of the
 Animal Kingdom, and of the chief forms of Fossil Remains. New
 Edition, revised and completed to the present time (under arrangement
 with the author), by W. S. DALLAS, F.L.S., in 2 vols., post 8vo (nearly
 600 pages each), illustrated with many hundred fine wood engravings,
 with a general Index, 6s. each.

Carpenter's Animal Physiology. New Edition,
 thoroughly revised, and in part rewritten, by the Author. With upwards
 of 300 capital illustrations on wood. Post 8vo, cloth, 6s.

**Carpenter's Vegetable Physiology and Sys-
 TEMATIC BOTANY.** A complete Introduction to the Knowledge of
 Plants. New Edition (revised under arrangement with the Author), by
 E. LANKESTER, M.D., &c., with several hundred illustrations on wood.
 Post 8vo, cloth, 6s.

De Jussieu's Elements of Botany. Translated,
 with considerable additions, by J. H. WILSON, F.L.S., with 750 capital
 woodcuts. Post 8vo, cloth, 6s.

DR. STEGGALL.
STUDENTS' BOOKS FOR EXAMINATION.

A Manual for Apothecaries' Hall
and other MEDICAL BOARDS. Eleventh Edition, 12mo, cloth, 10s.

A MANUAL FOR THE COLLEGE OF SURGEONS;
Intended for the Use of Candidates for Examination, and Practitioners.
Second Edition, 12mo, cloth, 10s.

GREGORY'S CONSPECTUS MEDICINÆ THEORETICÆ. The First Part, containing the Original Text, with an Ordo Verborum, and Literal Translation. 12mo, cloth, 10s.

THE FIRST FOUR BOOKS OF CELSUS; containing the Text, Ordo Verborum, and Translation. Second Edition, 12mo, cloth, 8s.

A TEXT-BOOK OF MATERIA MEDICA AND THERAPEUTICS. 12mo, cloth, 7s.

FIRST LINES FOR CHEMISTS AND DRUGGISTS PREPARING FOR EXAMINATION at the PHARMACEUTICAL SOCIETY. Second Edition, 24mo, cloth, 3s. 6d.

John Churchill, New Burlington-street.

Just published, 8vo, cloth, 8s.

Lectures on Chancre, delivered by
M. RICORD at the Hôpital du Midi, Paris. Edited and Translated from the French by C. F. MAUNDER, F.R.C.S. Demonstrator of Anatomy at Guy's Hospital.

To these Lectures are added numerous cases to prove the Duality of the Chancrous virus, but the Unity of the Syphilitic Poison; with the Diagnosis and Treatment of each variety of Chancre.

John Churchill, New Burlington-street.

Just published, fcap. 8vo, cloth, 3s.

On Diabetes, and its Successful

TREATMENT. By JOHN M. CAMPLIN, M.D. F.R.S.

"For these and other matters we must refer to the book itself, which is very creditable to Dr. Camplin, and well worthy the attention of practical men."—*Medical Times and Gazette*.

"Dr. Camplin's work is eminently practical; the instructions on diet possess much value, and the work should be consulted by every practitioner who has cases of diabetes to treat."—*Lancet*.

John Churchill, New Burlington-street.

Just published, with Plates, 8vo, cloth, 15s.

On the Organs of Vision: their

Anatomy and Physiology. By THOMAS NUNNELEY, F.R.C.S.E. Senior Surgeon to the Leeds General Eye and Ear Infirmary.

"Mr. Nunneley has handled his topics in a masterly manner, and has produced a very useful work. It is illustrated with a large number of beautiful diagrams."—*Med. Circular*.

"Mr. Nunneley in this volume has fairly made a field for himself, and by his original investigations on the structure of the eye, and thoughtful analysis of the laws of mind and feeling dependent on sight, has clearly acquired a right to publish and be heard on the subject of the organs of vision. . . . The plates and their descriptions alone give a high value to Mr. Nunneley's work."—*Athenæum*.

John Churchill, New Burlington-street.

With Engravings, 8vo, cloth, 7s.

On Leucorrhœa; its Pathology and

TREATMENT. By W. TYLER SMITH, M.D., Physician Accoucher to St. Mary's Hospital.

"This volume is of very great value. It is a book which ought to be in the hands of all interested in obstetrical studies."—*Edin. Monthly Journal*.

"The foregoing cursory examination of Dr. Tyler Smith's work will be sufficient to prove its value, and, we hope, more than enough to induce every practitioner to study it for himself. A blind attachment to a routine practice has hitherto often rendered the treatment of leucorrhœa nugatory, if not baneful."—*The Lancet*.

"We regard it as the most valuable, and, in every respect, as the best treatise which has yet appeared on the subject."—*Dublin Quarterly Journal*.

John Churchill, New Burlington-street.

Just published, fcap. 8vo, cloth, 5s.

An Introduction to Clinical Surgery;

with a Method of Investigating and Reporting Surgical Cases. By FURNEAUX JORDAN, Demonstrator of Anatomy at Queen's College, Birmingham.

"Mr. Jordan's work is one likely to prove of great practical utility, and we cordially recommend it to the notice of our Profession."—*Medical Times and Gazette*.

"The publication of this work is very opportune for students now about to commence in our schools the study of Surgery. To them we earnestly recommend it as supplying, in a compact form, all that they require which any book can give for the purpose of becoming competent to analyse, duly value, and correctly register the phenomena of surgical affections, to the literature of which it is a highly interesting addition."—*Dublin Quar. Jour. of Med. Science*.

"The symptoms and phenomena of surgical diseases and injuries carefully arranged."—*Brit. and For. Med.-Chir. Rev.*

"It is written with great care and clearness, and will, without doubt, do us share—not a trifling one—of work in fitting the surgical student for the efficient practice of his art."—*Brit. Med. Jour.*

John Churchill, New Burlington-street.

Just published, Second Edition, fcap. 8vo, 2s. 6d.

Hufeland's Art of Prolonging Life.

Edited by ERASMUS WILSON, F.R.S.

John Churchill, New Burlington-street.

Just published, with Engravings, post 8vo, cloth, 5s.

The Urine, in Health and Disease;

or, a Simple Explanation of the Physical Properties, Composition, and Uses of the Urine, of the Functions of the Kidneys, and of the Treatment of Urinary Disorders. By ARTHUR HILL HASSALL, M.D.

"For the production of a work like the present, a very full knowledge of the subject is required on the part of the writer, and for the successful execution of the task none could be better qualified than Dr. Hassall. . . . From its perusal the student or practitioner may in a brief period become acquainted with nearly everything connected with the urine and urinary disorders which is really important."—*The Lancet*.

John Churchill, New Burlington-street.

Fcap. 8vo, cloth, 6s. each volume,

Dr. Todd's Clinical Lectures.

Vol. I.—On PARALYSIS, DISEASES OF THE BRAIN.

Vol. II.—On CERTAIN DISEASES OF THE URINARY ORGANS.

"... Among these distinguished worthies, Dr. Todd holds his place most deservedly. He has laboured for the promotion of rational Medicine, not only by his personal exertions, but by calling forth and encouraging those of others."—*Med.-Chir. Rev.*

"Such are some of the most important topics touched upon in 'Dr. Todd's Clinical Lectures.' They exhibit throughout the impress of a thoughtful and well-cultivated intellect, and of a mind fully alive to all the resources of the Medical art."—*Med. Times and Gaz.*

"The volume before us emanates from one whose contributions to science for many years back have attested both ability and conscientious industry of so high an order as to render the perusal of anything coming from him a source of positive enjoyment."—*North Amer. Med.-Chir. Rev.*

John Churchill, New Burlington-street.

Just published, 8vo, cloth, 15s.

A Manual of Psychological Medicine:

containing the History, Nosology, Description, Statistics, Diagnosis, Pathology, and Treatment of Insanity. With Observations on the Modern Treatment of the Insane. By JOHN CHARLES BUCKNILL, M.D. Medical Superintendent of the Devon County Lunatic Asylum; and DANIEL H. TUKE, M.D. Visiting Medical Officer to the York Retreat.

"We congratulate our authors upon having so well sustained their high reputation by such a very valuable contribution to the literature of their country. The work is illustrated by a series of portraits of the different types of insanity, of great interest, and we commend it to our readers in the full assurance that they will derive pleasure and profit from its attentive perusal."—*Med.-Chir. Review*.

"This treatise must be regarded as one of the noteworthy publications of the day. . . . It will no doubt enjoy a very wide circulation, and this most deservedly."—*The Lancet*.

"Throughout, this work bears the evidence of much careful study and accurate observation, which cannot fail to obtain for its authors an increased reputation."—*Psychological Journal*.

John Churchill, New Burlington-street.

Just published, with Engravings on Wood, 8vo, cloth, 5s.

On Amputation by a Long and a

SHORT RECTANGULAR FLAP. By THOMAS P. TEALE, F.R.C.S., Surgeon to the Leeds General Infirmary.

"The various amputations described by Mr. Teale have been admirably illustrated by the drawings of Mr. Bagg. . . . His work should be studied by every surgeon."—*Med. Times and Gaz.*

"We heartily recommend Mr. Teale's mode of operating to the serious consideration of every hospital surgeon."—*Brit. and For. Med. Chir. Rev.*

"The favourable statistics of the modified operation will undoubtedly lead surgeons to give Mr. Teale's method of amputation a fair trial, since the drawings of the stump, photographed some months after the operation, are such as will compare most favourably with those obtained by any other procedure."—*American Journal of the Med. Sciences*.

By the same Author, 8vo, cloth, with Engravings, price 2s. 6d.

ON PLASTIC OPERATIONS FOR THE RESTORATION OF THE LOWER LIP, and for the Relief of several Deformities of the Face and Neck.

John Churchill, New Burlington-street.

8vo, cloth, 10s. 6d.

On Diseases of the Alimentary Canal,

ŒSOPHAGUS, STOMACH, CÆCUM, and INTESTINES. By SAMUEL O. HABERSHON, M.D., F.R.C.P., Senior Assistant-Physician to, and Lecturer on Materia Medica and Therapeutics at, Guy's Hospital.

"The practitioner will find it a very valuable work of reference."—*Medical Times and Gazette*.

"A long life with much practice, or a shorter one with the observation of a vastly concentrated mass of facts, could alone furnish the material of this work. We recommend Dr. Habershon's treatise as a valuable repository of clinical experience of very trustworthy character."—*The Lancet*.

"The work of Dr. Habershon treats of the diseases of the alimentary canal throughout its entire extent. In this respect it resembles that of Dr. Abercrombie, and on perusal it will be found to resemble it in the mode in which the subjects are discussed. In comparing this work to that of Dr. Abercrombie, we have already stamped it with a mark of high approbation."—*Dublin Quarterly Journal*.

John Churchill, New Burlington-street.

Just published, 8vo, cloth, 5s.

Observations on Naval Hygiene and SCURVY. By ALEX. ARMSTRONG, M.D., R.N.; Deputy Inspector of Hospitals and Fleets; Author of "A Personal Narrative of the Discovery of the North-west Passage."

John Churchill, New Burlington-street.

Third Edition, 32mo, cloth, 1s. 6d.

The Pharmacopœia of the Skin Hospital, containing the FORMULÆ and their Uses, as employed in 90,000 recorded Cases, and a Preliminary Address. By JAMES STARTIN, Surgeon to the Hospital.

"Practitioners will find in this little volume the composition of 1 the formulæ which have been gradually arrived at after an experience of 90,000 cases. Such a collection must prove interesting to practical men."

—Medical Times and Gazette.

John Churchill, New Burlington-street.

Just published, Second Edition, considerably enlarged, Plates, 8vo, cloth, 10s.

Stricture of the Urethra and Urinary FISTULÆ; its Pathology and Treatment. By HENRY THOMPSON, F.R.C.S., M.B., Assistant-Surgeon to University College Hospital, &c.

"Exhausting all that could be said of our present knowledge of the subject, we know of no modern monograph on Stricture which equals it."

—Edinburgh Monthly Journal.

John Churchill, New Burlington-street.

Second Edition, 8vo, cloth, 8s.

On Consumption: its Nature, SYMPTOMS, and TREATMENT. To which was awarded the Fothergillian Gold Medal. By RICHARD PAYNE COTTON, M.D., Fellow of the Royal College of Physicians, London; Physician to the Hospital for Consumption, Brompton.

"A work already well known to the Profession; additional information and experience render the present edition as complete as possible."

—Medical Times.

"The remarks added to the present edition increase the value of the book, which has once more our approbation and best wishes."

—British Medical Journal.

John Churchill, New Burlington-street.

Post 8vo, cloth, 6s. 6d.

Illustrations of Difficult Parturition, WITH PRACTICAL COMMENTARIES. By J. HALL DAVIS, M.D. Licentiate of the Royal College of Physicians, Physician to the Royal Maternity Charity.

"The author's position and large experience entitle his opinions to respect. . . . The Clinical Report contains one hundred and forty-four instructive histories, related in a clear, concise manner."

—Dublin Quar. Med. Journal.

"We must refer our readers to Dr. Davis's book for his opinions. . . . We feel high respect for his judgment and intelligence."

—Med.-Chir. Rev.

"The result of five-and-twenty years spent for the most part in the responsible and trying position of Physician to the Royal Maternity Charity is in due time and season produced in the form of an unpretending but satisfactory volume."

—Medical Times and Gazette.

"Amongst the many valuable contributions to Clinical Midwifery, this book of Dr. Hall Davis will, we think, occupy a permanent place."

—Lancet.

John Churchill, New Burlington-street.

Second Edition, post 8vo, cloth, 2s. 6d.

On the Treatment of Anchylosis; or, the Restoration of Motion in Stiff Joints.

By BERNARD E. BRODTHURST, F.R.C.S.

Senior Assistant-Surgeon to the Royal Orthopædic Hospital, &c. &c.

By the same Author, nearly ready.

A MANUAL OF ORTHOPÆDIC SURGERY; treating of the following Subjects, with numerous Woodcuts:—

1. Lateral Curvature of the Spine.
2. Affections of Muscles—such as Talipes, Torticollis, &c.
3. Affections of Joints—such as Anchylosis, &c.
4. Affections of Skin—such as Cicatrices resulting from Burns, &c.
5. Affections of Bones—such as Rachitis, Angular Curvature of the Spine, &c.
6. Arrests of Development.

John Churchill, New Burlington-street.

Just published, 8vo, cloth, 10s. 6d.

On Chloroform and other Anæsthetics:

their Action and Administration. By JOHN SNOW, M.D. Edited, with a Memoir of the Author, by BENJAMIN W. RICHARDSON, M.D.

"The man who has left us such a legacy cannot be said to have lived in vain; indeed, this volume is the only complete treatise on the subject which we possess."

—Lancet.

"A work in which the mode of action of anæsthetics is rigorously investigated, in which lucid and practical deductions are made on the basis of a vast experience, and extended and acute physiological researches, and where a method is laid down which is at once easy and successful."

—Brit. Med. Jour.

"A deep debt of gratitude is due to the late Dr. Snow, who worked out the practical details of anæsthesia, and devoted the study of a life to its development and improvement—his work may truly be styled a legacy to his sorrowing Professional brethren."

—Dublin Quarterly Journal.

John Churchill, New Burlington-street.

Just published, 8vo, cloth, 10s.

On the Influence of Variations of

ELECTRIC TENSION as the remote cause of Epidemic and other Diseases. By WILLIAM CRAIG, Licentiate of the Faculty of Physicians and Surgeons, Glasgow, and Consulting Surgeon to Ayr Fever Hospital.

John Churchill, New Burlington-street.

Just published, price One Shilling,

Hastings and St. Leonard's: their

Meteorology and Climate. By J. CHARLES SAVERY, M.R.C.S., L.S.A., Surgeon to the Hastings Dispensary, late House-Surgeon to the Northampton Infirmary.

John Churchill, New Burlington-street.

Just published, Second Edition, price 1s., per post 1s. 1d.

The Windpipe. New Views on the

Causes, Symptoms, and Treatment (chiefly Dietetic) of Irritative Congestion of the Windpipe, arising from public speaking, colds, &c. occurring also in certain stages of Consumption. By C. B. GARRETT, M.D. Hastings, late Physician to the Kingston Dispensary.

J. Churchill, London; and of the Author.

Just published, 8vo, cloth, 5s.

On the Hygienic Management of

INFANTS and CHILDREN. By T. HERBERT BARKER, M.D. Lond., F.R.C.S.

John Churchill, New Burlington-street.

of the CHEST. By PATRICK FRASER, M.D., late Staff Physician to the Army in the Crimea; Physician to the London Hospital.

John Churchill, New Burlington-street.

Fourth Edition, 32mo, cloth, 2s. 6d.

Shaw's Medical Remembrancer; or,

Book of Emergencies; concisely pointing out the immediate Remedies to be adopted in the first moments of danger from Poisoning, Drowning, Apoplexy, Burns, and other Accidents; with the Tests for the Principal Poisons. Corrected, with Additions,

By JONATHAN HUTCHINSON, M.R.C.S.

John Churchill, New Burlington-street.

Just published, 8vo, 2s. 6d.

Epiphora, or Watery Eye: its Successful

Treatment by the new Method of Dilatation. With Illustrative Cases. By JAS. VÖSE SOLOMON, F.R.C.S., Surgeon to the Birmingham Eye Infirmary.

John Churchill, New Burlington-street.

Now ready, with Plates, 8vo, cloth, price 7s. 6d.

The Enlarged Prostate, its Pathology

and TREATMENT; with Observations on the Relation of this Complaint to Stone in the Bladder. By HENRY THOMPSON, F.R.C.S., M.B. Assistant-Surgeon to University College Hospital.

"Shows careful research, much thought, power of accurate observation, great practical tact, and sound judgment. The book should be read by every Surgeon who treats or hopes to treat cases of diseased prostate."

—Medical Times.

"The best guide now on all these subjects."—Medical Circular.

John Churchill, New Burlington-street.

Just published, 8vo, price 2s. 6d.

Contributions to the Surgery of

DISEASED JOINTS, with especial Reference to the Operation of Excision. No. 1. THE KNEE. By P. C. PRICE, Surgeon to the Great Northern Hospital, the Metropolitan Institution for Scrofulous Children at Margate, &c.

"We can highly recommend this little work to all practical Surgeons, as one which will go far towards dispelling the doubts which are entertained by some regarding the propriety of the operation in question."

—Medical Times and Gazette.

"Mr. Price has done a considerable service to Surgery by publishing these observations. . . . Next to that of his old teacher, we do not know any whose name will be more honourably connected with excision of the knee-joint than his own."

—Medical Circular.

John Churchill, New Burlington-street.

Just published, post 8vo, cloth, 10s. 6d.

On the Diseases of the Stomach, with

an Introduction on its Anatomy and Physiology. By WILLIAM BRINTON, M.D., Lecturer on Physiology at St. Thomas's Hospital, Physician to the Royal Free Hospital.

"As one of our first writers upon the structure, functions, and diseases of the alimentary canal, the author of the present treatise has for some time established his reputation. We recommend Dr. Brinton's work as an honourable addition to the really scientific literature of the day."

—Lancet.

"These Lectures are intended to give a brief but complete account of what is at present known concerning the Diseases of the Stomach; the whole work will fully repay a careful study, and we heartily recommend it to our readers."

—Medical Times and Gazette.

General Debility and Defective

NUTRITION: their Causes, Consequences, and Treatment. By ALFRED SMEE, F.R.S. Senior Surgeon to the Royal General Dispensary, Surgeon to the Bank of England.

John Churchill, New Burlington-street.

In a few days will be published,

The Medical Registrar, pursuant to an

Act passed in the XXI. and XXII. Victoria, Cap. XC., to regulate the Qualifications of Practitioners in Medicine and Surgery. It may be obtained upon application (by letter or otherwise) at the office of the General Council of Medical Education and Registration of the United Kingdom, 32, Soho-square, London, W.

Price 7s. 6d. or post free 8s. (Office Hours from 11 to 4.)

Now ready, in One Vol. 8vo, pp. 370, price 7s. 6d.

A Treatise on Medical Electricity,

Theoretical and Practical; and its Use in the Treatment of Paralysis, Neuralgia, and other Diseases. By J. ALTHAUS, M.D.

Trübner and Co. 60, Paternoster-row.

Just published, in one volume, royal 8vo, pp. 992, handsomely bound in cloth, price 18s.

A Dictionary of Medical Science. By

ROBLEY DUNGLISON, M.D. LL.D. Fifteenth Edition, revised and very greatly enlarged.

It reviewing the fourteenth edition of this celebrated work, the "British and Foreign Medico-Chirurgical Review," for July 1853, page 205, remarked, that the labour which had been bestowed upon the work "had been something prodigious," adding, "the work, however, has been now done, and we are happy in the thought that no human being will have again to undertake the same gigantic task. Revised and corrected from time to time, Dr. Dunglison's 'Medical Lexicon' will last for centuries."

Yet, in the present edition, not only has the work been revised and corrected, but about six thousand subjects and terms have been added, which are not to be found in the one noticed by the "British and Foreign."

Trübner and Co., 60, Paternoster-row, London.

Just Published, Price 3s. 6d., with 200 Descriptive Cases, and Illustrations in Chromo-Lithography,

Amputations and Artificial Legs,

HANDS, &c. By W. R. GROSSMITH, of 175, Fleet-street, London. "Mr. Grossmith has offered some good practical suggestions for the consideration of the operator, and has entered more fully into the subject than has hitherto been attempted."—The Lancet, Nov. 14th, 1857.

"Mr. Grossmith's artificial limbs are well constructed, and on the best system."—Paris Exposition Jury Reports.

DR. LITTLE ON DEFORMITIES.

In 8vo, with 160 Engravings and Diagrams, 15s. cloth,

On the Nature and Treatment of

CONTRACTIONS and DEFORMITIES. By W. J. LITTLE, M.D. Senior Physician to the London Hospital, Founder of the Royal Orthopædic Hospital, &c.

CONTENTS.

1. Deformities in general. Treatment Operative, Instrumental, and Physiological. Forcible Extension under Chloroform.
2. Contractions from Wounds and Diseases of Joints, Accidents, Rheumatism, &c.
3. Contractions from Spasm, Paralysis, Burns, Habitual Retention in one Position.
4. Deformities from Rickets, Weakness, and Curvatures of Bones.
5. Congenital Distortions and Dislocations, Club-foot, Club-hand, &c.
6. Congenital Malformations, Monstrosities.
7. Distortions of the Spine, from Strumous Disease, Rickets, Lateral Curvature, Spasm, and Paralysis.

Appendix: On Relapsed and Neglected Cases. Index.

"The best treatise on the subject in any language."—The Lancet, the British and Foreign Medico-Chirurgical Review, and the Philadelphia Medical Examiner.

On CLUB-FOOT and ANALOGOUS DISTORTIONS, including their Treatment both with and without Surgical Operation. 8vo. Forty-one Engravings. 12s.

On ANCHYLOSIS or STIFF JOINT: a Practical Treatise on the Contractions and Deformities resulting from Diseases of the Joints. 8vo. Thirty-two Engravings. 7s. 6d.

London: Longman, Brown, Green, and Longmans.

BEST POPULAR BOOK ON THE MICROSCOPE.

In post 8vo, 6s. cloth extra,

The Microscope, its History, Construc-

tion, and Application. By JABEZ HOGG, Esq. The Fourth and newly revised Edition, with Five Hundred Engravings.

"The experienced microscopist will find in it not only much that is new to him, but hundreds of descriptions and engravings of objects that, some time or other, have occupied his attention; whilst the general reader will find in it much instructive information. Altogether it is a deservedly popular work, and one which should be found on the shelves of every well-furnished library."—The Lancet.

London: Routledge, Warrin, and Routledge, Farringdon-street.

24mo, cloth, 6s.

Practical Pharmaceutical Chemistry:

An Explanation of Chemical and Pharmaceutical Processes, with the Methods of Testing the Purity of the Preparations, deduced from original experiments. Translated from the second German Edition of Dr. G. C. WITTSTEIN, by STEPHEN DARBY.

This is an eminently practical and useful book, and only requires to be examined by the Pharmacist to ensure its being at once adopted as his guide and text-book. It gives, not only the best processes for the preparation of every chemical substance used in medicine, but such clear instructions for the manipulations and explanations of the chemical actions, that a student by its aid alone could prepare them with certainty and understand them fully. In fact, it would so far make him an accomplished chemist. But to those engaged in manufacturing medicine chemicals it must be extremely valuable, economising time and materials, and ensuring results as accurate and certain as if the object were merely scientific. This is of great importance, because the process recommended in treatises on purely scientific chemistry are not always applicable in working commercially, or in quantities, and therefore are not so useful to the Pharmacist. It is no less valuable in the shop than in the laboratory; the nature and composition of every chemical substance, including those derived from vegetables, the alkaloids, &c., are given in the most correct manner, together with the easiest and surest methods of testing their purity, and detecting admixtures or impurities, whether arising from defective manufacture or fraudulent additions.

The translator has performed his task very creditably. He has adhered to the use of the German nomenclature, which some may object to; but as the synonyms in use here are always appended, it seems to us to be judicious, as the free intercourse of this country with Germany and its people renders a knowledge of their terms of art and science itself a useful acquirement. We think the high encomiums bestowed on the work by that eminent Pharmacist Buchner, in a preface, are fully justified; and should it become, as it ought, the companion and hand-book of English Pharmacists, it will tend to elevate the profession by giving it a firm scientific basis, which will soon become manifest in improvements and discoveries in their science and art, where a wide field still exists to reward the diligent and skilful explorer.

John Churchill, New Burlington-street.

One Vol. 8vo, cloth lettered, price 8s. 6d.

On the Constitutional Treatment of

FEMALE DISEASES. By EDWARD RIGBY, M.D. &c.

"We know of no other obstetric writer who so strongly insists on the intimate connexion between uterine and constitutional disorders, or who has carried out this principle so consistently and so successfully. On this account we look upon the work as peculiarly valuable, and calculated to do an immensity of good at the present time, by dispelling the one-sided and narrow views so generally prevalent respecting this class of diseases, and placing their pathology and treatment on a sounder and more rational basis."—Dublin Quarterly Journal of Medical Science.

London: Renshaw, 356, Strand.

Second Edition, much enlarged, 1 Vol. 8vo, 400 Illustrations, £1 5s. cloth.

Erichsen's Science and Art of Surgery.

A Treatise on Surgical Injuries, Diseases and Operations. By JOHN ERICHSEN, Professor of Surgery in University College, London.

"Unhesitatingly we subscribe our opinion that this is the best English treatise on Surgery of our own time."—Dublin Hospital Gazette.

"In fulness of practical detail and perspicuity of style, convenience of arrangement, and soundness of discrimination, as well as fairness and completeness of discussion, it is better suited to the wants of both student and practitioner, than any of its predecessors."—American Journal of Medical Science.

OILED SILKS

FORTY-FIVE INCHES WIDE.

MORGAN'S ENAMELLED NON-ADHESIVE WHITE.

This is the only White Oil Silk that will allow of shipment to Tropical Climates, or that will remain in perfect condition even during an English Summer. It is entirely unaffected by heat, and may be dried by the Fire, or placed in Boiling Water without injury. It will also wear fully twice as long as the ordinary kind.

Packed in one-yard lengths, in strong ornamental boxes.

BLACK.

This Oil Silk will keep any length of time, in any climate, without the slightest deterioration. Packed same as the White.

LINTS.

MORGAN BROTHERS are now offering above, manufactured by new and greatly improved machinery, whereby they are advanced in quality and reduced in price.

PATENT FLAX (Super. A. Quality),

Possesses the following advantages:—

It is far lighter than the ordinary kind, consequently giving greater surface to the pound, is more economical, and being lighter, is therefore better adapted for Surgical purposes.

Being made from new Flax, bleached, wove, and cleansed from all impurities, and never previously used for clothing or domestic purposes, it may safely be relied on as containing nothing of a deleterious or contagious nature.

From its great absorbing powers it is well adapted for water dressings; it will also be found a most luxurious under-clothing in hot climates, for which purpose it is made in any length.

It also tears both ways.

A. packed in boxes with appropriate labels, each box containing 24 sheets, about 4 x 3 inches.

In this form, in addition to the ordinary uses of Lint, it will be found an excellent renovator of Razors, Surgical Instruments, &c.

PATENT LINEN (B. Quality),

Manufactured by the same machinery, is offered at the same price as Cotton Lint; and being free from the injurious properties of that article, must, when introduced, entirely supersede it.

PATENT COTTON (C. Quality).

This we still keep in stock, of the best quality only.

All our Lints are kept in stock in $\frac{1}{2}$, $\frac{1}{4}$, and 1 lb. parcels.

The $\frac{1}{4}$ and $\frac{1}{2}$ lb. are especially suited for fitting Medicine Chests.

LIBERAL TERMS FOR QUANTITIES OF ONE CWT. AND UPWARDS.

MORGAN'S ENAMELLED TRANSPARENT FOIL

Is stronger and lighter than the common French Oil Silks, at about one-fourth the price. Like their Enamelled Oil Silks, it is Non-adhesive and unaffected by climate.

MORGAN'S CORN AND BUNION PLASTERS will be found to instantly relieve the sufferer.

R. B. EDE and CO.'S COURT PLASTERS are the best that can be produced, and are kept in three colours, viz.—Black, White, and Pink.

The Profession may safely recommend any of the above, as being the finest known.

Samples and prices forwarded to large buyers.

The Profession may procure any of our articles through their Chemist and Druggist, or Surgical Instrument Dealer.

Each of the above articles bears our name.

MORGAN BROTHERS, Druggists' Sundrymen,

WAREHOUSE—1, 2, AND 5 $\frac{1}{2}$, JEWIN-CRESCENT, LONDON, E.C. FACTORY—BATTERSEA MILLS, SURREY, S.W.

MATHEY-CAYLUS'S GLUTEN CAPSULES.

THE ONLY ADMITTED TO THE UNIVERSAL EXHIBITION OF PARIS, 1855.

Adopted and Recommended for the Cure of Recent or Chronic Gleet, Fluor Albus, etc by the First Physicians of the Hospitals of Paris and of London.

EACH BOTTLE CONTAINS SIXTY-FOUR CAPSULES.

N.B. Experience has proved that it is sometimes necessary to vary the treatment according to the persistence of the disease, and the constitution or sex of the patient. To meet this requirement, M.-C. also prepares Gluten Capsules containing different substances capable of modifying advantageously the effects of the Copaiba, or of acting in a peculiar manner on the particular causes of the disease.

DESIGNATION OF THE DIFFERENT KINDS OF CAPSULES PREPARED BY MATHEY-CAYLUS.

- | | |
|--|---------------------------------|
| 1. Pure Copaiba. | 7. Copaiba and Catechu. |
| 2. Copaiba and Cubebs. | 8. Copaiba and Citrate of Iron. |
| 3. Copaiba and Rhatany. | 9. Copaiba and Magnesia. |
| 4. Copaiba, Cubebs, and Rhatany. | 10. Cubebs pure, or with Alum. |
| 5. Copaiba, Cubebs, and Carbonate of Iron. | 11. Venice Turpentine. |
| 6. Copaiba and Tannic Acid. | 12. Purified Norway Tar. |

MANUFACTURED BY

HOOPER'S HYDROSTATIC BEDS, OR MATTRESSES AND CUSHIONS, FOR PLACING ON AN ORDINARY BEDSTEAD.

WATER AT ANY TEMPERATURE MAY BE USED.

HOOPER'S FULL-LENGTH MATTRESS OR HYDROSTATIC BED,
For Bedsores, Cancer, Coldness of the Body, Consumptive Cases, Diseased
Joints, Dropsy, Fevers, Fractures, Gout, Gun-shot wounds.

HOOPER'S CUSHION FOR GENERAL PURPOSES.

ANY SHAPED CUSHION CAN BE OBTAINED,

For Inflammation of the Bowels, Lassitude, Paralysis, Rheumatism, Spinal Affections, Sloughing Sores, Ulcerated Cartilages, and all Invalids.

HOOPER'S PATENT INVALID BED-LIFT.

THE OBJECT of this INVENTION is to enable the Patient to be raised in any position above the Bed, so as to allow the Medical Attendant, or Nurse, to get any part of the body that may be requisite; and also that the Bed may be re-made, the chamber utensil used, and removed with facility.

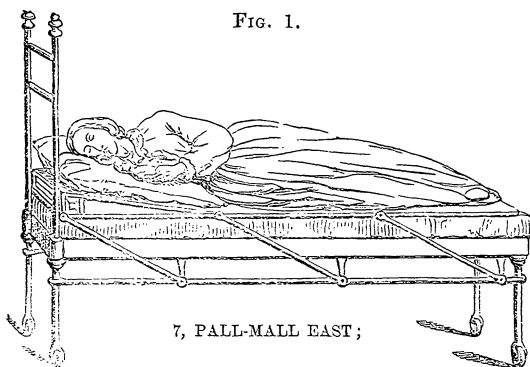

FIG. 1.

7, Pall-mall East;

FIG. 2.

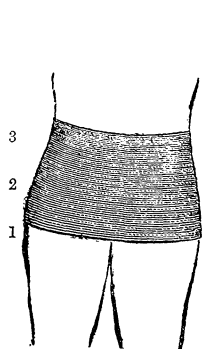

AND 55, GROSVENOR-STREET.

FIG. 1 represents a patient on the Patent Lift Bedstead, the
Lifting Apparatus not being in use.

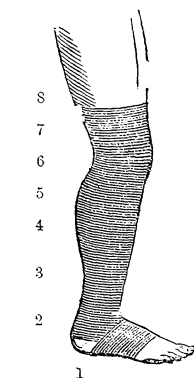

FIG. 2 represents the patient raised up from the ordinary level of the Bed by
means of the Lift, so as to enable the Medical Attendant, or Nurse, to perform
any of the offices before-named.

HOOPER'S SPIRAL ELASTIC SUPPORTERS.

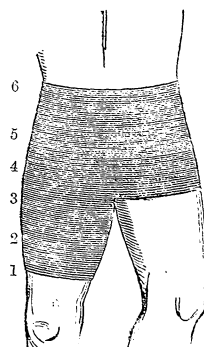

The Figures 1, 2, 3, &c. show the points at which the measures should be taken; the
length should also be stated.

ABDOMINAL SUPPORTER.

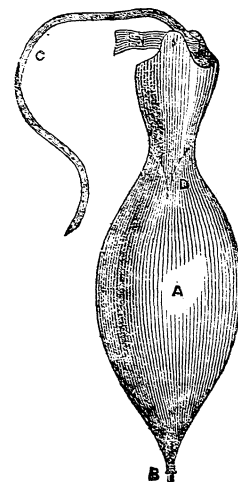

STOCKING ABOVE THE KNEE.

ABDOMINAL SUPPORTER AND
THIGH-PIECE.

HOOPER'S URINALS.

WITH VALVE TO PREVENT LEAKAGE,

Constructed of a light porous material, unique in giving continuous and permanent
pressure, can be accurately adjusted, and readily drawn over the parts requiring their
use.

For Invalids, or Railway Travellers; whether Sitting,
Reclining, or Walking; they are not affected by boiling
water, and may, therefore, be easily kept clean.

WATERPROOF SHEETING, FOR PROTECTING BEDDING

At a great Reduction in Price. It is soft and inodorous, and not acted on by Urine, Acids or Alkalis, and may be washed as
Family Linen.

S. M A W,
SURGICAL INSTRUMENT MAKER,
11, ALDERSGATE-STREET (near the General Post Office), LONDON, E.C.

A priced Catalogue (illustrated with nearly 300 Engravings) of all kinds of Surgical Instruments and Appliances, as well as of all the Implements, Utensils, and Apparatus, requisite for the Dispensing of Medicine, &c. may be had gratis on application as above. Detailed and Descriptive Lists of the following are given therein :—

PART I.

Amputating Instruments
Anatomical ditto
Army Surgeons' ditto
Bandages of every description
Crutches, &c.
Cupping Apparatus
Dental Instruments
Ear ditto
Elastic Stockings and Belts
Enema Apparatus of great variety
Eye Instruments
Fracture Apparatus
Inhalers
Lithotomy and Lithotripsy Instruments
Midwifery ditto
Minor Operation Instruments in Sets
Naval Surgeons' ditto
Pocket Cases of Instruments
Splints, &c.
Stomach Pumps
Trusses, &c.
Urethra Instruments
Uterine ditto
Urinals for Day or Night Use.

PART II.

Air-Beds, Cushions, and Pillows
Bed-Pans, Sheetings, &c.
Bolus and Palette Knives
Bottles, White and Green Glass, all kinds
Earthenware Funnels, Mortars and Pestles, Jars,
&c. &c. of every description
Glass Vessels of all kinds used in Dispensing
Labels
Lint, &c.
Markwick's Patent Epithems, Spongio Piline,
Impermeable Piline, &c.
Pill Boxes—Paper and Wood
Pill Machines
Plasters of all kinds
Respirators
Scales and Weights
Water-Beds, Pillows, &c.

PART III.

Comprises **FIXTURES**,—as Counters, Drawers, &c.

The above Catalogue especially commends itself to Gentlemen officially connected with Hospitals, Infirmarys, Dispensaries, Lunatic Asylums, &c.; all the requirements of such Institutions being supplied by S. MAW.

By Royal Letters Patent.

TAYLOR'S FLAX LINT.

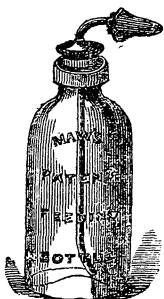

MANUFACTURED BY MACHINERY FROM NEW CLOTH.

This new and beautiful article is lighter and cheaper than the ordinary Lint, free from all impurity, soft and delicate, and does not adhere to nor fret wounds to which it is applied; and from the recent improvements made by the Patentee, it is altogether superior to that made heretofore, and gives a larger surface of Lint in each pound—facts certified by the ARMY AND NAVY MEDICAL BOARDS, the LONDON AND FOREIGN HOSPITALS, and by the MEDICAL PROFESSION in general. It is manufactured in any lengths, whereby it may be made available for under-clothing in hot climates; and being of a perfectly even surface, light, cool, and durable, allays irritation where the skin is excitable. It tears also both ways, and is so reasonable in price, as to admit of its being an appendage to the Dressing Case, as a cleanser or renovator to the Razor. In walking, if applied to the sole or top of the foot, it is grateful and pleasant. This Lint may be considered as a Luxury, and is applicable to a variety of purposes for which a harsh and unpleasant material has hitherto been used.

Sold by all Chemists and Druggists. Manufactured only by the Patentee.

SOLE AGENT—S. MAW, 11, ALDERSGATE-STREET, LONDON.

Packages having the Signature of the Patentee ("W. G. TAYLOR,") alone are genuine.

MAW'S PATENT INFANTS' FEEDING BOTTLE.

This is the best substitute for the natural breast, and is acknowledged by all who have tried it to be the only perfect Nursing Bottle yet introduced. By its use the supply of Food is regulated, and the child prevented drawing air; while the appliance by which this is accomplished is not liable (as others are, which are made of wood, bone, &c.) to get sour or out of order. It is not only the simplest Infants' Feeder yet invented, but is the cheapest, the price to the public being only 2s. 6d. each, including Nipple and Case.

S. MAW, 11, ALDERSGATE-STREET, LONDON, E.C.

ORIGINAL LECTURES.

CLINICAL LECTURES

ON

THE DISEASES OF WOMEN.

By J. Y. SIMPSON, M.D. F.R.S.E.

Professor of Medicine and Midwifery in the University of Edinburgh.

LECTURE XVII.

ON COCCYODYNIA, AND THE DISEASES AND DEFORMITIES OF THE COCCYX.

GENTLEMEN,—In the first bed at the right hand corner as you enter the ward for female diseases there lies a patient, whose history is interesting and instructive in more than one respect. But I call your attention to her case now inasmuch as she presents you with a well-marked instance of a disease of which you will find, I believe, no description in any book, and on account of which I have deemed it necessary to subject her to an operation, such as has not before, so far as I am aware, been performed, at least under similar circumstances. I shall, first of all, briefly relate to you the history of this case; then take occasion from it to make some observations on the nature and symptoms of the disease from which the patient suffers; and, lastly, try to point out to you how it may be most successfully treated.

E. F. a married female, of 40 years of age, has never had any children, but menstruated regularly and painlessly, and enjoyed good general health until about two years ago. At that time her menstrual discharges began to be more profuse and frequent than usual, and to be attended at times with pain. This she for a long time disregarded, believing the phenomena to be due to the "change of life;" but as she was becoming gradually weakened by the excessive losses of blood, she applied at my house for advice, about six or eight months ago, just after recovering from a severe attack of menorrhagia of three weeks' duration. In addition to the bloody discharges, and at the intervals between them, she suffered from a constant, fetid leucorrhœa; and she also complained of occasional shooting pains in the back and lower parts of the abdomen. She was much emaciated, and had a very cachectic appearance; and my nephew, Dr. Alexander Simpson, who then saw her, found the cervix uteri to be very much enlarged, indurated, and ulcerated; and it felt rough and irregular, like a commencing cauliflower excrescence, and bled freely when rudely touched. The ulceration and induration were not distinctly limited to the cervix, however, so that no hope could be entertained of curing the disease by amputation of the cervix uteri. But the dried sulphate of zinc was applied on several occasions, with the happy result of causing nearly the whole of the indurated and infiltrated mass to slough away, and there is now left a firm and healthy cicatrix. The patient does not now suffer from any unusual loss of blood, although she menstruates freely and regularly; and, so far as regards the uterus, she may be considered perfectly well, if we except a small hard knot in the anterior lip of the cervix, which may still, perhaps, be regarded as suspicious. But as she recovered from her uterine disease, and as the symptoms attendant on it began to disappear, she commenced to complain, after sitting on the damp grass in her avocation as a washerwoman of a dull, aching pain seated in the very lower extremity of the spinal column, for which my nephew contented himself with prescribing in the first instance a belladonna plaster, and afterwards various local anodynes and general tonics for a space of two or three weeks. As this pain, however, instead of abating, seemed always to become more constant and harassing, and as the patient could not sit down except on one hip at a time, and even then with the greatest suffering, an examination was made of the painful part, when it was found that the coccyx was unusually straight and long, so that it reached far backwards and downwards, while the very tip of it was felt through the rectum to be projected suddenly forwards. *Pressure of the coccyx and movement of it in any direction caused pain.* To subdue this sensibility thirty drops of a watery solution of the bimeconate of morphia were twice injected into the soft parts around the bone, on two different

occasions, and with an interval of several days between each injection. This measure had the effect each time of deadening the pain, but it led to no permanent result. The next step employed for her relief was the separation of the coccyx from all the surrounding muscles, tendons, and ligaments, which was done subcutaneously, with a tenotomy knife. Three or four weeks afterwards the patient returned, saying that for a time she had felt better, but that during the last week she had suffered as much pain as ever, and was incapacitated for work from it. She was, in consequence, sent into the Hospital; and on Saturday, June 3, I removed the two lower segments of the coccyx by cutting down upon them through the skin, and dividing the bone with a pair of bone-pliers; and then the separated portion being pushed through the wound by the finger of an assistant passed into the rectum, it was easily detached from the soft parts, and so removed. The edges of the wound were brought together with two iron wire stitches, which were removed some days afterwards, and the wound is now almost closed up.

Amputation of the coccygeal bones has been had recourse to in this patient, as it seemed to afford her the best chance of relief from a peculiar form of disease, which is anything but rare, although no written account of it has, as far I know, as yet appeared. If you will take the trouble to make inquiry of observing men in extensive practice, or if you have the opportunity of making the observation for yourselves, you will find that cases are ever and anon occurring, where the patient complains of pain in the region of the coccyx, very constant, and aggravated by certain movements of the trunk, and usually attributed by the patient to some kind of direct injury, or to exposure to cold. The most common cause of the disease, so far as I have been able to discover it from inquiries addressed to the patients themselves, is injury of the coccyx, inflicted either by falling backwards upon it, or, more frequently still, brought on by sitting down suddenly and forcibly on the corner of a chair or other angled body. Often enough, however, it is impossible to trace it to any traumatic origin; and the patient can only tell you, as in the case of our patient in the Hospital, that she had been sitting on damp grass, or had been otherwise exposed to cold before she began to experience the pain; or she may be altogether unable to adduce any assignable cause. I say she, because all the patients whom I have yet seen affected with this disease have been of the female sex; although I presume it is not entirely confined to them, and it is even not very clear why they should be more subject to it than the members of the other sex. I have said that when you have been made aware of the possibility of the occurrence of this complaint, and when you begin to look out for it, it is by no means very rare. Diseases, like other objects in nature, sometimes seem rare, not because they are so in reality, but merely because our attention has not happened to be fully called to the recognition of them as they pass before our eyes. I think you will hold me justified in making this remark, when I tell you that within the last three weeks I can count up at least ten cases of this particular malady which I have seen in private or consultation practice. Of course, it is a very unusual circumstance to meet with so many during such a short period; but it is not more wonderful than what often enough occurs in the experience of all Surgeons in extensive practice, who find that during a short space of time they may have a succession of cases all presenting the same form of injury, as an epidemic, as it were, of fractures or dislocations, and that a long period may elapse before they again meet with a similar case. Such a rapid succession of cases of the kind I allude to is, I repeat, of course an exceptional occurrence. But I know of old, and, on looking back upon many past years of practice, that I have seen and recognised a great many cases of this disease; and I have probably seen many others also, the true nature of which I did not at the time understand. It is, therefore, I believe, by no means an uncommon disease; and if you can discover and succeed in curing it, you will often get much credit to yourselves. That you may be enabled to do so, let me tell you how you are to detect it, or point out to you

THE SYMPTOMS OF THE DISEASE.

The leading symptom of the disease is pain in the region of the coccyx experienced by the patient whenever she sits down and rises, and sometimes while she remains in a sitting

posture. Most of the patients affected with it are obliged to sit on one hip, or with only one side resting on the edge of a chair, or with the weight partially supported by a hand on the chair; and they are rendered sometimes very awkward and miserable in consequence. Some of them actually dread sitting down—so great is the pain then felt; and not only so, but, as I have hinted already, the pain is in many cases aggravated or renewed whenever it becomes necessary again to resume the erect posture. There are other movements of the coccyx besides, which are liable to be attended in such cases with pain. Thus some patients have pain with every step they take in walking, while in others the movements of progression excite no uneasiness whatever. Others, again, feel the pain most when the bowels are being evacuated, or under any circumstances in which the sphincter or levator ani, or the ischio-coccygeal muscles are called into action. The pain is not in every case very acute or intolerable; and you will sometimes meet with patients who have borne with it for many years, sometimes without having sought any relief at all, sometimes in despair from the inefficacy of the remedies that have been employed. I have under my care just now a patient suffering from menorrhagia, who tells me she has been annoyed more or less for about twenty years with a pain of this description in the coccyx, not very severe, but which she has never found any means of alleviating, though formerly she consulted various physicians and surgeons on the subject. Again, the pain is not at all times equally severe in the same patient. When in Cumberland lately, I saw a lady who had kept her bed the whole winter, because of the excruciating pain which she experienced in attempting to sit upright or walk about; but who, at the time when I saw her, had got so far relieved as to be able to move about a little. The distinguishing feature of the disease in every case is that the pain is felt at the lowest part of the spine, or rather in the site of the coccyx, to which it is always specially referred by the patient, and where pressure always aggravates it. Pressure and movement of the coccyx, too, with the finger in various directions, produces pain, and the kind of movement which is thus attended with suffering, differs in different cases.

NOMENCLATURE OF THE DISEASE.

If it be desirable, as I think it is, to give the disease which I have described a distinct designation, I think that by availing ourselves of the Greek (*δδυνν*, pain), which enters into the composition of several names already sufficiently familiar to our ear, we can construct a name for this disease that will serve for its admission into a nosological list. We are constantly in the habit of speaking of pain in the side as pleurodynia, and the designations gastrodynia and mastodyn timer are in common use for pains in the stomach and pains in the mammae; and following this analogy, it seems to me that we might very conveniently refer to this painful affection of the coccyx under the analogous name of *coccydynia*. Besides that it is sufficiently terse to be easy of use, the designation presents this great advantage, that it involves no pathological theory as to the nature of the affection, but simply expresses its most striking symptom. But what theory can we form as to its proximate cause? or what, in other words, is

THE PATHOLOGICAL NATURE OF THE DISEASE?

I believe that the pain which is the characteristic of coccydynia is excited during the action of particular muscles, or particular sets of muscles, and that when the coccyx, or rather the coccygeal joints, have been in any way injured, or when it or its surrounding fibrous tissues have become the seat of inflammation, or other morbid change leading to super-sensitiveness of the part, any action of the muscles in connexion with it which causes motion of the coccygeal bones will, at the same time, give rise to a feeling of pain. Now, in order to understand aright the circumstances under which pain is likely to be produced by the action of muscles on an inflamed or otherwise diseased coccyx, I must beg of you to recall to mind your knowledge of its normal anatomy; and to revive your recollections on this subject, I show you here a sketch of the coccyx in its muscular and tendinous relations, which has been obligingly drawn for me by our able demonstrator, Dr. Cleland, from a dissection made for the purpose by my former class-assistant, Dr. Peter Young. (See Fig. 1.) This will serve to remind you that the coccyx gives attachment along either side to portions of the greater (a) and lesser (b) sacro-sciatic ligaments; and that as

regards muscles it has inserted into it, 1. the internal extremity of the fibres of the ischio-coccygei (f), which arise at their

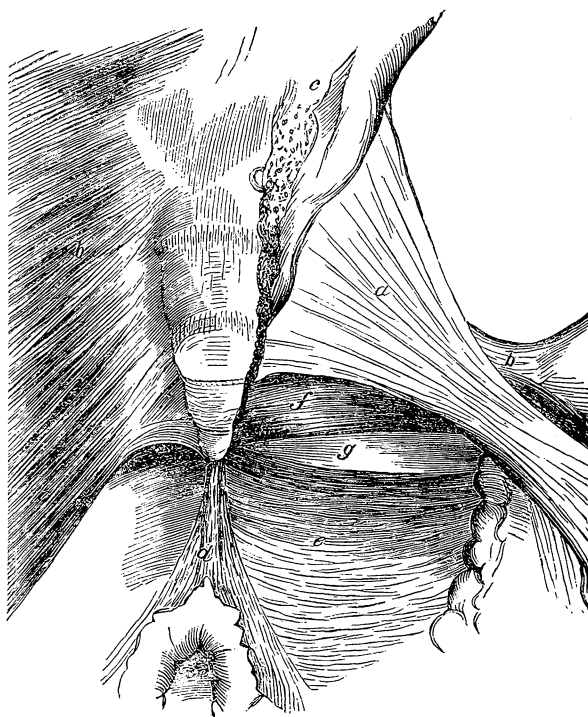

FIG. 1.—Sketch of the anatomical relations of the coccyx. a. Great sacro-sciatic ligament. b. Small sacro-sciatic ligament. c. Surface from which the gluteus maximus muscle (h) has been detached. d. Sphincter ani. e. Levator ani. f. Coccygeus muscle. g. Fascia in contact with the rectum. h. Gluteus maximus of left side.

outer extremity from the inner surface of the tuberosities of the ischia, and pass directly inwards to be attached to the outer border of the coccygeal bones along its anterior aspect; so that when both muscles are in action at the same time their tendency is to draw the coccyx somewhat forward, and when only one is in action the coccyx will be drawn to the corresponding side. Then, 2. from the extremity of the bone spring the tendon of the sphincter ani (d), and some of the fibres of the levator ani (e) which have a powerful effect in pulling the end of the coccyx inwards whenever any straining action of the muscles that close in the pelvis becomes necessary, as in defecation, coughing, etc. But, 3. the most powerful muscles connected with the coccyx are the large gluteal muscles (h) of either side, some of the tendinous and muscular fibres of which rise directly from the posterior surface of the bone (c), while others may come to act upon it indirectly by means of their origin from the great sacro-sciatic ligament. In sitting down and in rising up the glutei of both sides are simultaneously in action, and during progression when the body is swayed from side to side they act in succession. Now I have already told you that in some patients pain is experienced most severely during these movements, and I think that in them the pain is fairly referable to the traction upon the coccyx exercised by the great glutei muscles. Other patients, again, complain of pain chiefly when the bowels are being moved, and in them the sensation is probably due to the action on the coccyx of the sphincter and levator ani; while in a third class of cases pain may very possibly be excited during the contraction of the coccygeal muscles, as in the act of sitting down. It is by no means very easy to understand why the action of particular muscles should thus be attended with the production of pain in particular instances. It may be that the disease is confined to the tendons of the muscles or to the portion of the coccyx from which they spring; or, possibly, certain muscles during their action may bring the bone into contact with a super-sensitive nerve or inflamed structure, and in this way give rise to the painful sensation. Again, the fact of the disease being more common in women than in men, or being confined indeed almost exclusively to the former, may be due to the greater develop-

ment of the gluteal muscles, which results from the larger size of the female pelvis. It is not necessarily due to lesions sustained during parturition, although sometimes so produced; for it occurs as frequently in the young and unmarried as in those who have passed through one or more confinements; and more probably it is dependent in some way on the peculiar form and large size of the female pelvis, and on the greater development of the gluteal and perineal muscles which result therefrom. But, however that may be, we have most convincing proof that the pain is elicited by the action of the muscles in the fact that separation of the fibres of these muscles from the coccyx often affords the most effectual and instantaneous relief. And this leads me to speak next of

THE TREATMENT OF THE DISEASE.

Formerly, before I knew much of the nature of the complaint, I used to have recourse to many different remedies, and many different modes of treatment, in order to procure for my patients relief from their pain. Opium, in its various forms, belladonna, hyoscyamus, and a variety of other sedatives, were all administered internally, or applied locally; but only in general with the most temporary benefit. Suspecting that the pains might have somewhat of a rheumatic character, I in some instances caused the patient to make use for a length of time of the remedies which are usually most efficacious in the treatment of diseases dependent on the rheumatic diathesis; and in other cases I have administered the various preparations of iron, zinc, arsenic, and other antineuralgic tonics for a lengthened period; but generally none of these modes of treatment seemed to afford any real relief, and by none of them have I ever succeeded in effecting a permanent cure, except in a very limited class of cases. There are some cases where the pain seems to be due to acute inflammation, probably of the sacro-coccygeal articulation, or of some of the joints between the several segments of the coccyx itself; and in such cases I have seen great benefit result from the application of leeches over the part, followed by counter-irritation, while the patient was kept at perfect rest, and subjected to other antiphlogistic treatment. I have sometimes tried the use of acupuncture needles; and not infrequently I have had recourse to the subcutaneous injection of a solution of morphia into the tissues around the coccyx; and this plan of treatment, which is usually so successful in the treatment of local neuralgias, has comparatively seldom had the effect in this disease of relieving the pain, and never, so far as I can remember, of producing a perfect and permanent cure. All kinds of constitutional treatment, and most forms of topical applications, are often, however, almost or altogether of no avail for the cure of this disease; and the only means of obtaining radical relief—and happily it is a means which proves successful in almost every case—is the complete separation from the coccyx of the muscular and tendinous fibres that are in connexion with it. To effect this, you must introduce a tenotomy knife underneath the skin, at a short distance from the tip of the coccyx, pass it along the posterior aspect of the bone, and then divide the muscular and tendinous attachments, first on one side and then on the other, and finally all round the tip of it. It is not in every case necessary to make such a free division as I have indicated. In some instances division of the fibres of the gluteus maximus of one or the other side will suffice, or detachment from the coccyx of the sphincter and levator ani may be all that is requisite for a cure. This simple operation is easy and rapid of performance, like other examples of subcutaneous Surgery is not attended with bleeding, and is attended with no great degree of suffering; and the result is in almost every case instant relief of the pain, and in most cases a perfect and permanent cure of the disease. In illustration of these remarks, perhaps you will allow me to read you the history of a case of this disease which was cured in the manner I have described to you. The patient was a lady from India, who came under my care several years ago; and the history of her case, which I am now about to read to you, was drawn up for me by the lady herself.

"On the 5th November, 1852, while taking my usual morning ride on my favourite horse, about fifteen hands in height, he suddenly shyed. I was thrown, and so severely shaken and injured that I fainted on the spot, and could not suffer to be touched or moved for a considerable time thereafter. On being taken home I fainted again, from the excessive pain in the lower extremity of my body, which

baffled all and every remedy to alleviate or remove; and for six weeks I could neither turn nor attempt to move from my couch. At length I began to get about again, suffering great inconvenience from my accident both in a sitting and reclining posture—the latter especially, which in travelling caused me intense and most excruciating torture. Indeed, after travelling some hours in a carriage, I quite dreaded getting up to step out of it, as I could not do so without severe spasms. I returned to England early in 1853, and hoped its bracing climate would speedily rectify all that was amiss with my back; but in this sanguine expectation I was disappointed, and still doomed to drag on a miserable and wretched existence up to the 4th March, 1855, when, as if by magic, I obtained immediate relief from a slight operation performed upon me by Dr. Simpson."

The treatment in this case consisted, I say, of the isolation of the coccygeal bones from the surrounding tissue by means of a tenotomy knife; and the result of this simple operation has proved as satisfactory and permanent as the relief obtained by it was instantaneous and complete. In the case of another lady, from India, who had long suffered from coccydynia, while I was performing the same simple operation to effect her relief, an accident occurred. I was dividing the last fibres of the coccygeal attachments, when the slender knife gave way, and broke among the dense structures. I told the patient of it, and she at once raised herself up in alarm to hear of the calamity; but before I had done telling her of what had happened, she had had time in sitting up to discover that she had been cured of her disease, and rejoiced at the discovery. She quickly replied, "Oh! never mind; my pain is gone—let the knife remain." And there, for aught I know, it remains to this day—an illustration of a pathological law to which I have already directed your attention in the course of these lectures—viz. that pieces of iron and other metals may remain in contact with the living tissues, and may lie imbedded in their midst for any length of time, without giving rise to any marked degree of inflammatory action. And the striking effects of this simple operation for the cure of coccydynia are not confined to those cases where it is had recourse to at a comparatively early period of the disease. I have under my care just now a patient who has been a martyr to it for twelve years past, and who night and day used to suffer great pain whenever she made any movement of the body. Yet in her case, isolation of the coccyx in the manner I have described to you, produced immediate relief, and ever since the operation was performed, a fortnight ago, she has been perfectly free from pain.

I have met with one or two cases of coccydynia, however, which I have failed to cure by means of this operation; and where division of the muscular and tendinous fibres—even the most complete—and thus setting the coccyx perfectly free and perfectly at rest for a time, has merely eased the pain temporarily without relieving the patient of it altogether. In our patient in the Hospital the operation proved thus unsuccessful, and, therefore, I put in practice, what I had often thought of having recourse to, the more radical measure of removing altogether the coccyx or a portion of the bone. This amputation of some of the segments of the coccyx was resolved on the more readily in her case, because in her the several bones of it seemed firmly ankylosed, and it at the same time projected unusually low down, and was turned suddenly inwards at the tip. Making an incision of about two inches in length through the skin stretched tightly over the end of the bone, I exposed the latter, and having separated it from its connexion with the soft parts, and divided it between the second and third of its vertebrae with a pair of bone pliers, its two lower segments were easily removed. I have another patient suffering from this disease, in whom I have repeatedly had recourse to the isolation of the coccyx by means of the tenotomy knife, but always with the effect of producing only a temporary relief; and in her case I have long proposed to perform an operation similar to that performed in the patient in the ward, if the results prove as favourable as we desire, and as there seems at present every reasonable prospect of attaining. Removal of portions of the coccyx is an operation that has been performed more than once before, in cases of necrosis in some of its segments; but I believe its performance under the circumstances I have been describing to you, is altogether novel.

I have said, that as a general rule, the result of constitutional treatment of any kind affords us little hope of being able

to cure this disease by its adoption. But, as I have already hinted, there is a class of cases, of which I have seen a few rare instances, where the pain seems to partake somewhat of a neuralgic character, and where I think I have seen the patient benefited by the use of the remedies which are usually employed for the cure of neuralgic affections. At all events, wherever you find a patient complaining of pain in the coccyx, who at the same time is affected with pains in the other parts of the body, and who has the unhealthy chlorotic aspect common to those subject to neuralgia, you would do well in such a case to put your patient through a course of iron, arsenic, zinc, manganese, or other nerve tonics, or to make her use some of them in combination for a time. By this means you may possibly succeed in curing the coccydynia and in dispelling her other symptoms; and should that plan of treatment fail in effecting a cure, it will still form a very good and safe measure preliminary to the adoption of the severer but more certain operative procedure. I would only add, in connexion with this point, that there is a leash of nerves lying all round the coccyx; and I once imagined that the relief obtained by isolation of the bone was due to section of these nervous cords; but now the explanation of the phenomenon which I have already given you seems to me to be the more probable, and that when the coccyx is separated from the surrounding tissues, no more pain is experienced, because the bone is by this means freed from the action of the muscles formerly in connexion with it, and is thus placed in a condition of absolute rest.

As I am speaking of the coccyx, you will allow me to add that, if more attention were directed to the pathological and anatomical history of this organ than has hitherto been accorded to it, it would probably be found to be subject to diseases and disorders such as have hardly been even suspected. In the wide field of anatomical and pathological investigation, gentlemen, there is still much room for original observation and research; and the corner of it, to which I am now trying to turn your attention, has hitherto remained entirely unexplored. We have no thesis or monograph of any kind on the subject of the coccyx in its pathological relations; yet the organ is subject to various morbid conditions which are well worthy of careful examination. I have been telling you something about one of these morbid states, to which I have ventured to give a name and a place in pathology; and now, to interest you still more in the matter, and to show you in what direction inquiry might be most profitably directed, let me briefly indicate to you some of the other lesions to which the coccyx is liable. And, first, a word or two as to the

INJURIES OF THE COCCYX IN CONNEXION WITH PARTURITION.

The coccyx is, as you know, articulated to the lower end of the sacrum by a joint resembling those which unite together the several vertebræ higher up in the spinal column; and this sacro-coccygeal articulation is sometimes found to be inflamed, as a result of injury sustained during the parturient process. While labour is going on, as the head of the child descends along the floor of the pelvis, the coccyx can often be felt to be stretched very much backwards, and under the strain to which they are subjected some of the fibres of the anterior ligaments which bind this bone to the sacrum may be torn and give way, and in the joint thus exposed and injured inflammation is very apt to be set up. I have seen it swell up and become very painful from this cause after delivery; and in one case the inflammation thus set up led to the formation of an abscess. Or without producing any such immediately bad effects, the inflammatory process may subside and end merely in the production of ankylosis of the sacrum and coccyx, and then the evil effects of it may pass unnoticed till the patient comes again to be in labour, when it will be found that the unyielding bone presents a great obstruction to the progress of the fetal head. A good many cases have been put on record where it was averred that fracture of the coccyx had occurred during labour, and where, probably, the accident was of this nature, that the sacrum and coccyx had become ankylosed together as a result of some foregoing inflammation in the joint; and under the pressure to which the coccyx was subjected during parturition the morbidly adherent bones became again disunited. If the coccyx be turned very much inwards towards the cavity of the pelvis at the time when it becomes united to the lower end of the sacrum, the obstruction which it then offers to labour will be much greater than when it remains

in its normal position after ankylosis had taken place, and it may then be found necessary to have recourse to some operative measure to promote the progress, and to admit of the termination of the labour. What operation should be performed in such a case? Some say that it then becomes necessary to destroy the child, and to effect delivery of the mother by means of craniotomy; but if you will observe the course pursued by nature when allowed to terminate such a case unaided, you will find that she has a much simpler plan, which you can easily imitate, and by following which you may succeed in bringing the labour to a successful termination, without having recourse to the dreadful operation of craniotomy. What nature does in such cases I had once an opportunity of observing in a patient who was confined in the old Lying-in Hospital here. In a former labour this patient had suffered some injury of the coccyx, which ended in its becoming ankylosed to the sacrum at such an angle as to cause it to project inwards towards the cavity of the pelvis, where it now formed a firm and unyielding obstacle to the progress of the fetal head. For when the head descended to the point in the floor of the pelvis, where the point of the coccyx was protruding, it was there arrested, and remained fixed and immovable for a length of time, when at last, during a strong contraction of the uterus, the projecting bone gave way under the pressure of the child's head, the adherent bones were separated from each other, and the child was speedily expelled. And in every case of this kind, I think it would be better to break up artificially the morbid union that exists between the sacrum and the coccyx, than to have recourse to the deadly alternative of the destruction of the infant.

SURGICAL INJURIES OF THE COCCYX,

by which I mean fractures and dislocations of the bone occurring accidentally and independently of the parturient process, are not of very frequent occurrence in ordinary every-day practice, although a good many cases have been put on record. They were mostly produced by the patient having fallen backwards; and the striking features peculiar to every case are—1. The intense pain suffered by the patient when the coccyx was moved, as in the act of defecation, coughing, or walking; and 2. The instantaneous and complete relief afforded by the reduction of the displaced bone. I should like to cite to you two of the cases of this kind that have been published—one, because you have all the more common symptoms of the injury very concisely and touchingly recorded; the other because of the peculiar manner in which reduction of the dislocation was effected.

Smetius, a Professor of Medicine in the University of Heidelberg in the end of the sixteenth and beginning of the seventeenth century, has left a kind of diary on record of some of the most interesting cases that fell under his observation during the space of forty-eight years, and among other entries there occurs the following delectable entry:—"1588, October 27th.—My wife has fallen backwards, and so injured the coccygeal bone, that she cannot sit without great pain, nor can she empty the bowel or the bladder, or cough without much distress."

In the "Ephemerides Medico-Physicæ," one Gustavus Casimirus Gahrlipe tells of an accident that befel his father-in-law, an old septuagenarian, who in descending the steps of a palace when they were slippery with ice and snow, lost his footing, and fell with the lower end of the trunk against the stone stairs. He sustained a fracture of the os coccygis in consequence, but said nothing about it to his daughter, a young girl, who was the only person living with him at the time. He could get no passage in his bowels; and his daughter, believing this to be the cause of the distress which she saw him labouring under, administered some aperients, but without affording any relief. He had become seriously ill on the fifth day, when he spoke of his accident to a sagacious friend, who told him that perhaps his spine was injured, and advised him to allow himself to be rolled and tumbled and pushed about, as he lay on a wooden couch, by two robust women. He followed his friend's advice, and with the happiest result; for by the jostling the end of the os coccygis which was bent inwards was restored to its situation, and the obstruction being removed the bowels were moved *cum impetu summo*.

Allow me to quote a third case, which will show you in what a simple manner this accident may sometimes be

occasioned. Tobi a Meek'ren, an old Surgeon of Amsterdam, gave to the world in his "Medico-Chirurgical Observations," among other cases, one in which this accident—dislocation of the caudal bones—took place. The patient, he tells us, was a female, addicted to the sect of the Anabaptists, who went to the watercloset, and not knowing that the lid was down, suddenly injured her coccyx, so that she could neither sit nor stand, and was obliged to be carried to bed. On the second day the pain became greater, and she fevered and got convulsions; and then Meekren was called in in consultation with her ordinary attendant. They suspected the nature of the case, but the modest lady would not allow herself to be touched. But during the night her sufferings became so intolerable that her medical advisers had to be summoned again early in the morning; and this time they were allowed to reduce the dislocation which afforded her instantaneous and complete relief.

But besides being liable to be turned forwards, whether as a result of inflammation or injury during the process of parturition, or as the effect of direct violence from a fall or blow, the coccyx is found in some cases to project unusually far backwards. I do not refer now to those cases of which there are some few on record, and in which this dislocation of the coccyx backwards has been produced during labour, and has remained afterwards as a permanent but usually painless condition; the variety I allude to belongs rather to the class of

MALFORMATIONS OF THE COCCYX.

In the woman in the hospital the coccyx was unusually straight, and the general inclination of the bone was somewhat backwards, although the last segment of it was turned rather abruptly forward and projected towards the rectum. In her case it is not easy to determine whether this condition of the bone was present from birth, or was the result of some injury in after life. But in a late number of the *Dublin Medical Press*, Dr. Wilson gives an account of a patient with a projection resembling a tail, attached to the lower end of the spinal column; and in the last number of the same journal there is a paper by Dr. Jacob, reprinted from the *Dublin Hospital Reports*, in which he describes a tumour of this kind that had been amputated by his father, and in which he speaks of a family several of whose members presented this remarkable variety of malformation. In the "Chronicles of Lanercost" it is related that the Norman sailors used to believe the Englishmen to be furnished with tails, and when they had to execute them they hung them always with a dog alongside, thus anticipating the principle of *similia similibus*.

DEFICIENT DEVELOPMENT OF THE COCCYX

has sometimes been seen as a rare instance of deformity. The number of segments is liable to much deviation; but its total want, or its existence in a merely rudimental condition, is rare. Perhaps the most frequent and striking instances of this kind of deformity occur in the domain of Comparative Anatomy. Thus in the Isle of Man there is a breed of cats, all the members of which are born without tails, the coccygeal bones being reduced in number to a very few, and these rudimentary in character. Absence of the caudal bones, I repeat, in man is a rare phenomenon, although their existence at all is not often suspected by those who have no knowledge of anatomy, some of whom have entertained the most singular ideas on the subject. Perhaps no theory was more singular than that of Lord Monboddo, an old Scottish judge, who believed that the absence of the tail was a phenomenon peculiar to the modern human races, and that the modern curtailment of this appendage was a result of their higher degree of civilisation. The worthy judge, at an early period of his investigations, believed that we must all be still born with tails, and that possibly the wise women and the doctors cut or twisted them off the moment the child was born. It used even to be told against his Lordship, that on one occasion when an addition was about to be made to his own family, he was caught hiding in the bedroom, in some corner of which he had secreted himself with a view of watching all the proceedings, and witnessing for himself the removal of the new-born infant's tail.

TUMOURS OF THE COCCYX—DOUBLE MONSTROSITY BY INCLUSION.

But leaving the mythical and mysterious part of the question, let me call your attention to this sketch (see Fig. 2) of the posterior aspect of an infant, whose entrance into the world created a great deal of noise some three years ago, and

regarding whom a paragraph appeared in many newspapers, headed, "CURIOUS MONSTROSITY—A CHILD BORN WITH A

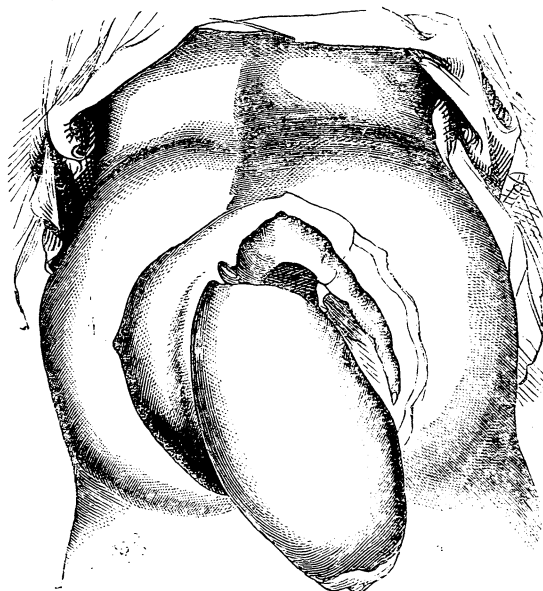

FIG. 2.—Sketch of the coccygeal tumour attached to the child. Dr. Richardson's case.

TAIL." The case occurred in the practice of my friend, Dr. Richardson, of Stockton-on-Tees, who relieved the child of its extraordinary appendix by amputation, and who had the kindness to send me the tumour for dissection along with this sketch of the child taken before the performance of the operation. The tumour, which is of an oval form and about six inches in length, by four in breadth, was attached to the skin of the back opposite the middle of the sacrum by a narrow rounded neck of about an inch in diameter, through which two or three small vessels passed into the tumour. At the lower end, which projected slightly beyond the level of

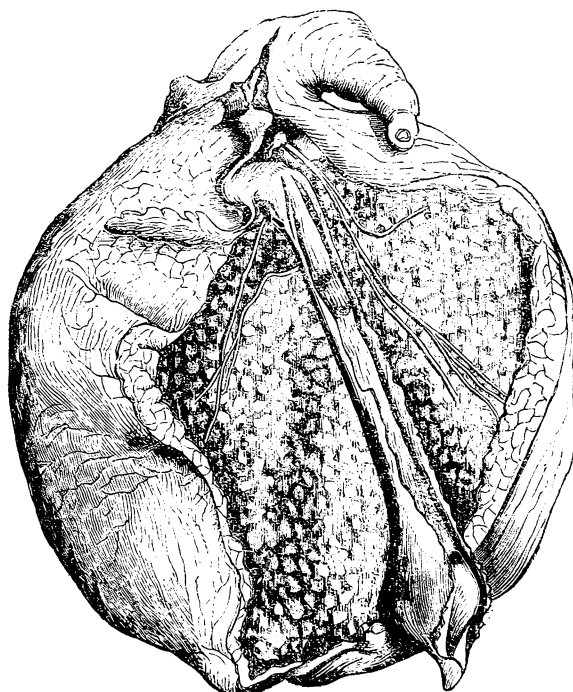

FIG. 3.—Sketch of the coccygeal tumour dissected. the folds of the nates, there was a slight depression, through which a point of bone could be distinctly felt, while from the

upper extremity, on the surface which was turned towards the back of the infant, there grew a projection about two inches in length, which bore a perfect resemblance to a finger or toe, containing, as it did, two bones like phalanges, and being furnished at the tip with a well-developed nail. The skin of the child's back immediately surrounding the point to which this tumour was attached was altered in character, and resembled in appearance the mucous membrane of the lips, while the skin in contact with this peculiar structure was thickly covered with hair. The child was in perfectly good health; and, Dr. Richardson very wisely determined upon relieving it of its extraordinary encumbrance, which he succeeded in doing with perfect safety by first tying a cord round the neck of the tumour, and then cutting it off beyond the ligature. There was no remarkable degree of hæmorrhage, only one vessel requiring to be tied; and the infant showed no bad symptoms afterwards, while the wound speedily closed. On dissection, the tumour was found to consist, as you here see (see Fig. 3), of a mass of fat enveloped in skin, and containing in its midst a long bone, running nearly through the entire length of the growth, while a number of vessels and nerves came through the neck and were distributed throughout the mass. The bone was well ossified and invested by periosteum; but it does not present a sufficiently well-marked resemblance to any of the bones in the human skeleton to enable us to decide as to its real nature. It bears more resemblance to a tibia, however, than to any other bone. Towards the upper end of the one side it has attached to it a portion of tissue, redder in colour and denser in texture than the rest of the substance of the tumour, and almost resembling muscle in appearance.

Now, what is the nature of this curious caudal appendix? It is simply an instance of a kind of malformation which occurs when two ova have been impregnated, and when only one of the fetuses comes to maturity, while the other is blighted at an early stage, and arrested in its development, but becomes adherent to some part of the body of its co-twin, where it appears at birth in the form of a tumour. Tumours of this kind may be found adhering to different parts of the bodies of infants, and we occasionally meet with cases where they are attached to the very lower extremity of the trunk and in connexion with the coccyx or region at least of the coccyx. I show you here a drawing of a child (see

FIG. 4.—Sketch of a coccygeal tumour which presented at birth.

Fig. 4) with a large sacculated tumour of this description growing from the between the nates. In this case the

tumour presented at birth, and proved a source of great difficulty to the practitioner in attendance, who could not make out the nature of the case until the birth of the lower half of the body had been effected. In the practice of Dr. Paterson, of Leith, a similar case occurred about eighteen years ago, when a boy was born with such a tumour growing from the lower part of the back of the pelvis. This tumour (see Fig. 5) was seen by a good many

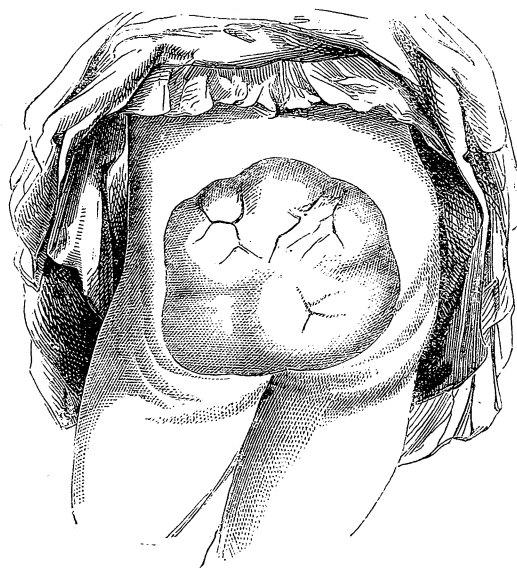

FIG. 5.—Sketch of a coccygeal tumour occurring in a child born eighteen years ago and still living. Dr. Paterson's case.

different medical men, and very different opinions were entertained as to its nature, but most were inclined to the belief that it was a case of spina bifida. I had just been reading Meckel's work on Double Monsters, in which he describes some cases of this kind, and came then to the conclusion, which I still believe to be the correct one, that Dr. Paterson's patient was another instance of a fetus born with an undeveloped one attached to it; but the bearer of that supernumerary fetus still lives, and as the tumour was never removed there has been no means of verifying the diagnosis. Here is still another drawing (see Fig. 6) of a case of this

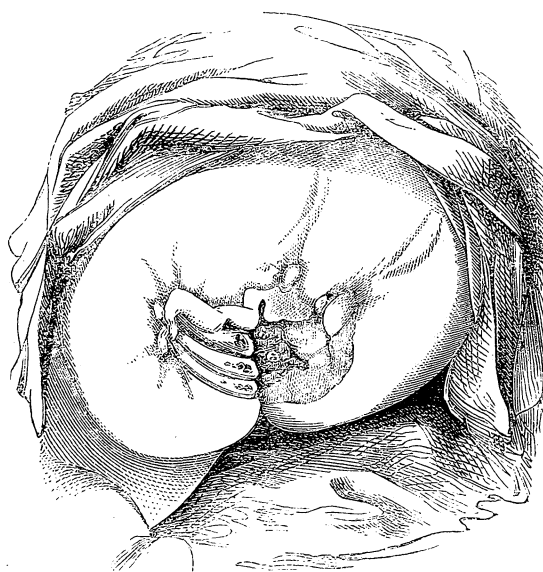

FIG. 6.

nature, occurring in the person of a girl, who came into the Hospital several years ago with a cystic mass attached to the back opposite the sacrum and coccyx, which had been there

at birth, and which still continued to grow. A portion of the growth was removed, and it was found to consist chiefly of a few large cysts, which gave out an intolerably offensive secretion. There are some preparations of this kind in the museum of St. Bartholomew's Hospital in London, and among others a preparation of a supernumerary undeveloped fœtus, which was removed from the lower part of the back of an adult female by Mr. Wormald. The tumour in this case, Mr. Wormald writes me, seemed to come from the interior of the pelvis, and as it grew the sacrum and coccyx were turned upwards and backwards. It was of enormous size, requiring an incision on each side of twenty-five inches in length for its removal, and on examination afterwards it was found to be composed of a mass of cysts, some of them containing a watery fluid, others steatomatous matter, hairs, fat, and osseous deposits. The patient gradually recovered from the operation; but the sacrum and coccyx never returned to their normal position. A gentleman died a few years ago, the heir to a Scottish earldom, who had a tumour growing from the lower and back part of the trunk, regarding which endless consultations had been held during his lifetime. It was often discussed whether it would be safe and proper to remove it; and when he died, at the age of forty, it was found that this tumour, which had been a source of discomfort and uneasiness to him all his life, might very easily have been removed.

If you inquire into the nature of these tumours you will find them to vary very much as regards their structure. Sometimes they consist of masses of fatty substance alone; sometimes they contain bones, rudimentary, or more or less developed; or they may contain teeth. Some of them have been found having a jaw-bone with teeth in the sockets. Portions of intestine and portions of other organs and parts of the body have at times been found in them, all tending to show that they are merely instances of secondary blighted fœtuses attached to well developed ones, and obtaining nourishment from them. Some of these secondary fœtuses remain in the most rudimentary condition possible, presenting only a cellular mass. Others again contain tissues more highly organised; and some of them present traces of parts approaching in development to the organs and parts of their more perfect mates. These additional fœtuses attached to the sacrum and coccyx form a puzzle, however, to teratologists in this respect, that they cannot be found to be regulated in any way by a law which holds good in the case of double monsters of almost every other description. In all the common types of double monsters it is a law that like is always attached to like in the two bodies. Thus the chest of one child is always attached to the chest of another, the back to the back, a sternum to a sternum, an occiput to an occiput, an artery to an artery, a nerve to a nerve, the corresponding bone, muscle, artery, nerve, etc. of one body, to exactly the same corresponding bone, muscle, artery, nerve, etc. of the other body of the double monster. But to this law there are some few and rare exceptions. Thus I have in my hand the skeleton of a fully developed kitten which has the pelvis and posterior extremities of a secondary fœtal kitten attached to the lower end of the sternum. Such a union of unlike parts is very rare, and we may perhaps deduce a lesson from it in transcendental anatomy, as to the analogy between the pelvic and sternal bones. And the coccygeal tumours in question form also, I repeat, a very striking exception to a law which is so general; for in them you have parts and tissues of the secondary fœtus attached to parts and tissues of the developed child that are not at all similar. What are we to do in the way of

TREATMENT OF THESE COCCYGEAL TUMOURS?

When they can be removed with safety to the infant, it will, of course, always be advisable to do so; but it is not always very easy to decide upon the safety of the operation. In such a case as that of Dr. Richardson, where the tumour was pediculated and attached by a narrow neck, and where no tissue of importance was present in the isthmus, the operation was safe, and the result satisfactory. The same may be said of Mr. Wormald's case, and of some others; but sometimes, as I have told you, portions of intestine pass out from the body of the child into the coccygeal tumour, and whenever there is any suspicion of the presence of such a communication the operation had better be left undone. Where removal is to be effected at all, it is best to do it as Dr. Richardson did, as

soon after birth as possible. In the case of the girl in the Hospital, bad ulcers formed in the opened tumour, and exhaled such odours as to render her presence intolerable to all the other patients. In the case of Dr. Paterson's patient, nothing at all was done, and the cystic mass has shrunk up and become reduced in size, instead of becoming developed along with the rest of the body; and the young man, who is now a clerk in a public office, works all day at his desk sitting upon, and in one sense at least supported by, this undeveloped brother.

ORIGINAL COMMUNICATIONS.

THE EMPLOYMENT OF WATER IN AUSCULTATION.

By S. SCOTT ALISON, M.D.

Assistant Physician to the Hospital for Consumption.

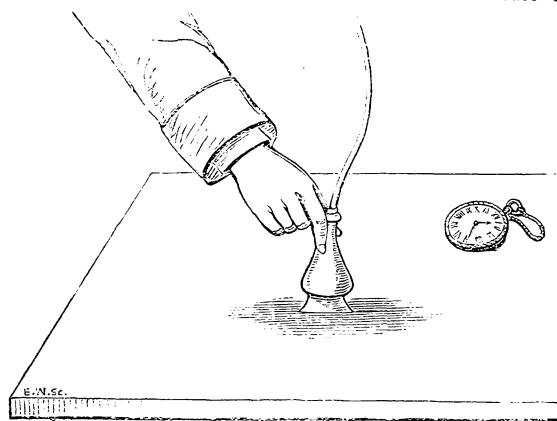

WHEN lately engaged in performing experiments upon the propagation of sound, I ascertained that water placed between the aperture of a hearing tube and a solid sounding body, gave an increase to the sound conveyed to the ear without it, and that a sound so near as to be inaudible without water so interposed was made audible by the addition of this medium of communication. For example,—a watch placed upon a table would be moderately well heard when listened to through a hearing-tube with its aperture placed immediately upon that table; but would be better heard when the aperture of the hearing-tube was placed in water lying upon the table; and the sound of a watch removed to some distance upon the table, though not heard by means of the aperture of the hearing-tube placed directly upon this body, would be rendered audible by interposing water.

The amount of increase of sound thus procured by the interposition of water is very considerable, and is such as very materially to add to the value of hearing-tubes when employed upon the sounds of solid bodies. The increase of sound is very striking; an impression is made upon the mind as if the sound were proceeding from a body greatly larger than it really is; the sound is louder; it is also fuller and softer. If the sounding body be listened to through a double stethoscope, such as my differential strethophone or phonoscope, which has two apertures for conveying sounds separately to both ears; and if in the case of one of these apertures water be interposed, such is the increase of sound so produced, that the mind becomes conscious of the sound in that ear only, having the advantage of the interposed water. The mind now becomes unconscious of any sound in the other ear; although, previous to the employment of the water, the mind was perfectly sensible of it. This phenomenon forms a good test of the water having produced a stronger auditory sensation; for I have ascertained that the same sound conveyed in a major intensity to one ear sensorially nullifies a minor impression from the same sounding body conveyed to the other ear. This is the test of restriction of hearing to one ear, or of uno-aural hearing.

The quantity of water which will give an increase of sound need not be more than a fine film under the hearing-tube, and extensive enough to connect the entire circumference of the aperture with the solid sounding body. When water in such small quantity is employed the increase of sound is made more obvious by holding the aperture of the hearing-tube very lightly upon the solid body, and the result may be made still more remarkable by raising the edges of the aperture a very little from the solid body, taking care to preserve the water in contact with its entire circumference, and also in contact with the solid body, the water, in fact, being preserved in the shape of a ring, with one edge in contact with the hearing-tube and with the other in contact with the solid body.

In the case of sounds, such as those of a watch, a greater increase of sound is obtained by employing a large quantity of water, such as a tumblerful or a bowlful; but if a very great amount of water be employed, such as that in a large cistern, and the hearing-tube be placed at one extremity and the sounding body at the other, no increase may be obtained, and indeed the sound may be rendered inaudible,—for it is to be remembered that sound

diminishes in the ratio of the square of the distance, and water gives no exception to this law. For an increase of

sound to be procured the diminution from distance must be less than the augmentation from the intensifying property of water. In the case of sounds, such as are produced by striking one large stone upon another upon the dry ground, an intensification of sound may be procured, although the water intervening may be many feet in extent.

The increase of sound procured by the interposition of water varies much with the material of which the hearing tube is formed. Wooden and metallic plate-tubes, such as are firm or non-flexible, receive no advantage from water; tubes such as the flexible stethoscope and ordinary hearing or speaking tubes acquire a material reinforcement from water, while tubes made of india-rubber gain a very great advantage from the interposition of this medium. It may be stated, as a general rule, that the more a hearing-tube becomes a mere air instrument, and departs from the character of a solid conducting instrument, the more water adds to its acoustic value. When a tube, by means of firm solid walls, becomes more of a solid conductor of sound, water becomes less useful, till at last, as in the case of a wooden stethoscope with only a fine bore, it diminishes sound, and acts as a damper.

The construction of hearing-tubes materially affects the results obtained from the employment of water. A tube which is provided with an ear-piece that enters the meatus externus serves to show the augmenting property of water more than one having a circular disc to cover the external ear. A cup or expanded extremity, for the collection of sound, serves likewise to increase the reinforcing power of water. The contraction of the tube beyond the cup to the uniform size of the external meatus favours the same result.

Whatever interferes with the free undulations of the air contained in the tube reduces the property of water under consideration. If a piece of membrane of the greatest tenuity be stretched across the tube or bore of the instrument, between the cup or aperture and the aural extremity, the result is materially reduced.

If a tube be converted into a solid body by closing up the hollow part, water far from increasing the sound heard, materially reduces it. A solid rod of wood, such as a ruler or a solid stethoscope, is deteriorated by water employed in the manner under consideration.

The evenness or unevenness of the surface of sounding bodies materially affects the result obtainable from water when hearing-tubes are employed. The augmentation of sound is much greater when the surface is rough and uneven, and thus prevents the exact fitting of the cup of the hearing-tube upon it.

The consistence of solid bodies naturally affects the result of the employment of water. The effect is greater in the case of hard resisting bodies, such as wood or stone, than of softer bodies, such as leather.

The freedom or constrained position of the cup or the tube, in respect of capability of vibrating, very materially influences the action of water. If the cup be held firmly by the fingers the result is greatly deteriorated. If the cup be pressed to the bottom of a vessel containing water, the sound heard is greatly less when it is kept free in media aqua.

In order that water shall augment sound in the manner under consideration, viz. from solid bodies through hearing-tubes, it is necessary that the water come in immediate contact with the aperture of the tube, or be separated from it only by some thin moveable or vibrating body, such as thin india-rubber, gutta-percha, or other membrane, or other solid body which, in reference to the strength of the sound, shall be small and vibratory. A thin membrane offers little impediment in the case even of a fine delicate sound, but a thin layer of wood, the one-fiftieth part of an inch in thickness, will materially counteract the augmenting power of water in the case of a fine sound, such as that of a watch or even of a tuning-fork. The more the intervening solid body is indisposed to vibrate, the more it interferes with the sound-augmenting property of water. For a layer of wood one-twelfth of an inch thick, placed between the water and the hearing-tube, to admit of the advantage of water being even in some degree manifested, the sound proceeding from the solid body beyond the water must be very loud, and capable of violently agitating the water, and the wood placed between it and the hearing-tube. Layers of india-rubber offer much less impediment to the augmenting power of water; these, in fact, act as membranes. Thin membranes offer no sensible impediment whatever.

When hearing-tubes are to be employed lower than the mere surface of water, and we desire to have the fullest possible amount of sound, it is necessary to close the lower aperture of the tube, so that the water shall not enter into the interior of the instrument. If this be not done no sensible increase of the sound is obtained by carrying the instrument lower in the case of a hearing-tube of uniform diameter, or a simple cylinder, and a great reduction of the sound is observed in the case of a hearing-tube which is provided with an expanded bell-shaped or other widened aperture, such as the cup extremity of the stethoscope. It is very different with tubes, whether cylindrical or expanding at the apertures, closed with membranes; for the more these instruments are sunk the greater is the amount of sound procured. The increase of sound procured by sinking such an instrument is very great, provided the solid sounding body be not far distant.

In the experiments of M. Collodon, in the Lake of Geneva, in 1826, a cylinder of uniform diameter was employed, and it was closed at the bottom with tin, the same material of which the walls were constructed. It was three yards long and eight inches in diameter. This hearing-tube was provided neither with a fine tube to pass into the ear, nor with an expanded extremity for the better collection of sound, so that as a hearing-tube instrument it was very defective, having, besides, the disadvantage of a solid bottom. But in some of my experiments upon sound in water proceeding from solid bodies, I have employed an instrument having all the advantages of construction possessed by an ordinary hearing-tube, viz. a cup or expanded extremity or aperture, for collecting the diverging pulses, so to speak, of sound, and to converge them together; a narrow tube to carry these converged pulses, and an open extremity to pass into the external canal of the ear, so that the sonorous pulses, without suffering diminution by escape into the external air, should impinge upon the membrana tympani and the solid walls of the meatus. These advantages of construction in hearing tubes are as desirable in dealing with sounds in water as with sounds in air; and, if the precaution above referred to be adopted, are as completely obtainable. When an expanded extremity or aperture is closed with membrane and sunk deep in water, all the sonorous rays which reach the aperture act upon the air within the aperture, and are continued on through the column of air to the ear; but if the membrane be withdrawn the water rises into the open aperture and reaches to the narrow part of the tube, the area of which may be perhaps only one-twentieth of that of the aperture, consequently the sonorous rays or pulses which reach the column of air in the tube are greatly less. Besides this disadvantage, there is another and a greater—the free vibration of the materials of the expanded extremity of the hearing-tube consonating with the external water in a state of sonorous undulation is very materially impeded, and its reaction upon the contained column of air and upon the surface of the water in contact with the air is interfered with by the presence of the water in the interior. The resistance of the water in the interior is sufficient to interfere with the undulations of the walls of the tube on which so much of the

advantage of hearing-tubes depends. That the admission of water reduces to a great extent the vibrations of the tube may be at once proved by placing the fingers upon the instrument: the vibrations are sensibly reduced, and may be even rendered altogether imperceptible to the touch.

By the interposition of water between a solid sounding body and the aperture of a hearing-tube, sound is conveyed further than by employing simply a hearing-tube without water; so that when it is necessary to convey a sound far through a hearing-tube water may be advantageously employed; but it is not to be forgotten that whether we employ water or dispense with it, sound is liable to decay, and that as the distance travelled increases the intensity of sound diminishes.

These observations having been made, I proceed now to the consideration of the employment of water in the auscultation of the sounds of the human body, and more especially of the morbid sounds of the chest.

(To be continued.)

CASES ILLUSTRATIVE OF THE ORIGIN OF TYPHUS FEVER FROM OVERCROWDING.

By CHARLES MURCHISON, M.D. L.R.C.P.

Assistant Physician to King's College Hospital, and to the London Fever Hospital.

It is only by an accurate discrimination of the different forms of continued fever that we can hope to arrive at a knowledge of their causes. Recent researches have shown that the poison of typhoid or pythogenic fever is generated in the putrid emanations from decaying animal matter, while that of the true typhus is produced by the condensed exhalations from living bodies, more especially when the persons exposed to them have for some time previously been in a destitute condition.

From the circumstance that pythogenic fever is but sparingly, if at all, contagious, and that outbreaks of it are always of a very limited and circumscribed character, it is by no means difficult to connect this disease with its cause. Abundant evidence now exists in proof of this connexion; and I need only refer to the "Westminster fever" of 1848, the Croydon fever of 1852, the Cowbridge fever of 1853, that of the National Hotel at Washington in 1857, and the "Windsor epidemic" of 1858.

Typhus fever, on the other hand, prevailing in great epidemics, and being eminently contagious, is with more difficulty in individual instances traced to its originating cause. When widely prevalent in large cities it is seldom possible to exclude the possibility of contagion; and hence, in order to demonstrate the nature of its origin, I have hitherto been compelled to refer to the first appearance of the disease in large and isolated bodies of men, such as armies. In periods like the present, however, when typhus is very rare, we may succeed in tracing its origin in single families and individuals.

Dr. John Hunter, Physician to the army, has recorded in the third volume of the *Transactions* of the College of Physicians an instance of typhus originating from overcrowding, which occurred in London in 1779. A family, consisting of husband, wife, and several children, had been lodged for some time in a room from twelve to fourteen feet square, and had been very badly off. The disease could not be traced to contagion, and typhus was by no means prevalent at the time.

Two remarkable instances of this nature have recently come under my notice, and deserve being put on record.

I. In a "Report on the Prevalence of Continued Fevers during the year 1858," published in the *Lancet* for April 2, 1859, I stated, that, while there had been no diminution below the average number of pythogenic cases, during the nine months from June 1858 to February 1859 inclusive, only two cases of typhus with the characteristic eruption had been admitted into the London Fever Hospital, although in 1856 the numbers had amounted to 1062. All at once in March, seven characteristic cases were admitted from one house, 10, Meridian-place, Bermondsey. It became an interesting point to investigate the precise conditions under which this fever appeared. The following account is drawn up, partly from inquiries made by myself on the spot, and partly from a com-

munication, for which I am indebted to Dr. Challice, the Medical Officer of Health for the district.

1. The court in which the house is situated is paved and open at both ends, and is about 11 feet wide. The drainage in the court appears to have been in a satisfactory condition. In fact, only a year before, great improvements had been carried out. All the cesspools had been emptied and filled up; the drains trapped and the water let on. The privy in No. 10, was furnished with a soil pan and trapped, as was also the sink. These facts are important, inasmuch as the fever was not that which results from the putrid emanations from drains.

2. The house, No. 10, consists of two floors, connected by a very narrow staircase. There are two rooms on each floor: and in each room, a door, a single window, and a fireplace. All the rooms were little better than closets, their dimensions being as follows:

	Length.	Width.	Height.	No. of Cubic Feet.*
	Ft. In.	Ft. In.	Ft. In.	
1. Ground Floor—Front room ..	8 9	8 6	8 0	595
Back " ..	8 6	8 0	8 0	544
2. Upper Floor—Front room ..	11 2	8 6	7 2	680
Back " ..	8 6	8 2	7 2	497

* In this and the following instance I have made no allowance for the space occupied by the furniture.

The doors of the rooms on the ground floor open into a passage not more than two feet wide. The windows in all the rooms can be opened; but throughout the winter, and up to the outbreak of fever, they had been so seldom or never.

3. A mother with her six children occupied the two rooms on the ground floor. The mother was aged 34; and the respective ages of the children were 18, 17, 15, 10, 7, and 3. Three slept in one bed in the front room; and four in the back room. After the fever broke out the grandmother of the children came from Dover to nurse them, and she also slept in one of the rooms. The rooms upstairs were occupied by a man and his wife.

4. It will thus be seen that before the arrival of the grandmother seven human beings occupied 1139 cubic feet of space, or each individual had only 163 cubic feet. After the arrival of the grandmother there were only 142 cubic feet to each.

5. There were no means of ventilation. Dr. Challice describes the rooms as having at that time the "peculiar animal odour always noticed in cases of overcrowding and dirt." The habits of the family were filthy in the extreme. The parish inspector found the rooms "alive with vermin;" and the nurses in the Fever hospital declared that they had scarcely ever known patients admitted in such a filthy condition.

6. The father of the family was a sailor, and had been at sea for many months; and although the family were not absolutely penniless, the mother spent most of their little earnings in gin.

7. There were no other cases of fever in the court or in the immediate neighbourhood. Indeed, true typhus was at the time excessively rare throughout the whole metropolis. None of the members of either family had, as far as could be ascertained, been exposed to any contagious disease. Shortly afterwards, however, several cases of typhus occurred in the next house, and two were admitted from it into the London Fever Hospital.

8. The mother and eldest child appeared to have become first affected about the end of February. Three others of the children were seized during the first week of March, and a fifth in the second week. The sixth child, the youngest, escaped. The mother and five children were admitted into the Fever Hospital on the 12th and 15th of March. All recovered. The grandmother, who came from Dover early in March, took the fever, and died on the 15th, at 10, Meridian-place. The man, who resided up stairs, was taken ill (contagion?) about the 9th of March, was admitted on the 15th, and died on the 22nd. His wife did not take the fever.

II. The next cases of typhus admitted into the London Fever Hospital came from No. 5, Henry-passage, St. Pancras. The following is the sequence of events concerning them:—

1. The fever first appeared in a family residing on the ground floor of this house, and consisting of a father, aged 54; a mother, aged 40; and six children, of the respective ages of 16, 14, 12, 10, 8, and 5.

2. These eight persons resided and slept in two rooms, which together contained only 1378 cubic feet of space, making an allowance of only 172.5 cubic feet to each individual. This I ascertained from personal examination. Each of the two rooms was furnished with a door, one window, and a fireplace. The mother informed me, that during the winter, and previous to the outbreak of fever, the windows had seldom been opened.

3. The whole family had long been very destitute, the father having for many months been out of employment.

4. No source of contagion could be traced. These were the first cases of typhus in the court and in the neighbourhood. But, on the other hand, they formed a focus of contagion, whence other cases originated. Shortly after, cases appeared in the next house, one of which was admitted into the Fever Hospital. A sister also of the mother's in No. 5, came from an adjoining street to attend upon her. She caught the fever, as did also her husband and child; and all three died. A third sister came to nurse this last one, from another street in the same neighbourhood. She was taken ill shortly after with fever, as were also her husband and child. The husband died; and the mother and child are still ill. Here, indeed, we have a melancholy instance of the lamentable results which may accrue from a neglect of sanitary precautions in a single family.

Now, in the above cases, it may be argued, that we cannot be positively certain that the disease was not primarily introduced by contagion; and, indeed, the same objection may be raised to every similar instance. I would reply, that at the period in question there were no cases of typhus in the immediate neighbourhood; that no member of the families first affected had been exposed to contagion; and that typhus was at the time scarcely to be met with, either in the metropolis, or in any part of the kingdom. If the objection has any weight, we must admit that the contagious specific poison of typhus is always and everywhere present, ready to manifest itself, whenever (and only then) the causes, which I have supposed to generate it, are present.

79, Wimpole-street, W.

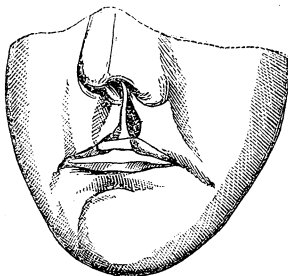

ON THE OPERATION FOR HARE-LIP.

By JOHN DIX, M.R.C.S.

Surgeon to the Hull and Sculcoates Dispensary.

SOME months ago, I performed the following operation for hare-lip, on an infant six weeks old, with an excellent result; and, I believe, the modifications which I adopted will be found worthy of imitation.

The accompanying woodcut will explain better than words the plan of the operation.

I first freely separated the gingival adhesions of each portion of the lip,—the essential first step in all such operations, as every one knows, though it is not always sufficiently attended to.

Next with a cataract knife, I proceeded to pare the outer edge of the fissure, commencing the incision above and continuing it nearly down to, but not through, the free edge of the lip, leaving the slip attached below for future use, instead of cutting it away.

This cut was not made in the usual manner, directly from before to behind, but in a slanting direction so as to remove much from the anterior surface, and little or none from the posterior.

On the opposite side this arrangement was reversed, so

that most was taken from the mucous surface, and scarcely any from the skin; and here not merely was the detached piece cut away, but also, by another cut, the terminal convexity of the fissure was freely excised as far as the median line. This last excision removes most, from the anterior, cutaneous aspect.

To this last raw surface the little flap from the other side was subsequently adapted, and united by very fine continued suture—the deep parts having been first accurately adjusted and fixed with a single needle and twisted suture.

The results of this mode of proceeding will be readily seen,—and I believe them to be advantages.

First, the denuded surfaces are larger, and the adaptation is effected between two bevelled edges, one of which overlaps the other, instead of between two flat surfaces applied side by side, in which the contact cannot be so intimate, so extensive, or so readily maintained.

Secondly, none of the length of the lip from side to side is cut away, so that the parts come together with less tension, and therefore with greater chance of union.

Thirdly, the rounded extremities of the fissure, which are frequently more or less visible in after life, are entirely got rid of; one by turning down the flap which includes it,—the other by excision, which may be practised all the more freely, because the loss will be repaired by the aforesaid flap from the other side.

In this case a portion of the transplanted slip did not live to adhere where it had been fixed; but enough remained to fill up the inequality which so often persists, and which it was especially intended to remedy. In a subsequent operation I hope to obviate this slight mischance by making the flap of rather larger size, and therefore of stronger growth.

I have never seen a case in which the operation was more entirely successful—the notch is completely obliterated, and even superseded by a little bead-like projection, which is the natural configuration of a child's lip, and which is here formed by the union and contraction of the "little flap."

One other point on which opinions differ in reference to operations for hare-lip I cannot pass over in silence, particularly as I have in this case myself violated what I believe to be the rule of safety and also of true professional morality, viz. the age at which such operation should be performed. The danger of hæmorrhage in very young children is well known. From this cause I have myself seen not less than three deaths in cases of operation for hare-lip on infants of seven or eight weeks old. In a child of eighteen months or two years old such an operation is, I suppose, entirely free from risk to life. How great then is the responsibility of the Surgeon who places a human life in needless jeopardy by advising or adopting surgical proceedings at a period when they are by no means free from danger,—which hazard may be altogether obviated by a few months' delay.

Of course special circumstances may justify a departure from this rule of practice—for instance, a child may be unable to suck, so that its life is endangered by lack of nutrition; or the parents may be importunate and insist on an operation earlier than the Surgeon thinks advisable—such was the case in the instance I have related above.

The kind of incisions above described so as to produce bevelled edges, may be advantageously adopted in other operations on the lips and face. In this way I lately removed an epithelioma from the lower lip of a man aged 45 years. Perfect and immediate union took place, and no cicatrix is observable without careful search.

With reference to this case it is worthy of observation that the man had never smoked.

THE BARK OF THE LIME-TREE, Dr. Kirn informs us, when boiled for some time, becomes soft, supple, and takes any form, retaining it when cold. It thus becomes a kind of substitute for gutta-percha.

DR. MERCIER has written a pamphlet of ninety pages, which has already reached a second edition, in order to explain the nature of J. J. Rousseau's illness, and the influence it had upon his writings. Spermatorrhœa he believes to have been at the bottom of all Jean Jacques's grievances! Lallemand also had the same idea. Is this pamphlet an advertisement? Surely the weaknesses of this *Ermite de Ermenonville*, of this *doloureuse pénitent de l'humanité*, might be left quiet.

THE LONDON
PRACTICE OF MEDICINE AND SURGERY.

ST. BARTHOLOMEW'S HOSPITAL.

CONTRACTION OF THE ADDUCTORS OF THE
THIGHS AFTER FEVER.—TENOTOMY.

(Under the care of Mr. PAGET.)

Mr. Paget has under treatment a case in which the adductors of both thighs are contracted in a very singular and unusual way. The patient is a moderately stout and healthy looking girl. Some time ago, she suffered from fever, and was confined to her bed for some weeks, and on recovery found that her thighs had been drawn in and stiffened. On examination the adductor muscles might be felt very rigid indeed, and the knees were found firmly pressed together. It was thought possible that there might be some hysteria in the case, and chloroform was administered. Under its influence, however, no relaxation took place, and it was clear that the condition was quite independent of the will. Mr. Paget has accordingly divided the tendons of the long adductors on both sides, and the girl is now kept on her back in bed, with the knees drawn forcibly outwards by straps. Mr. Paget remarked the other day at the patient's bedside, that this form of muscular contraction was very rare, so much so, that he did not recollect to have ever seen a similar case.

PROPRIETY OF AMPUTATION FOR TRAUMATIC
GANGRENE.

(Under the care of Mr. STANLEY.)

We mentioned a fortnight ago, an important practical case, in which the question as to the propriety of amputating on account of extensive gangrene of the leg was entertained in a consultation which included the three Senior Surgeons of this Hospital. That the conclusion came to was the right one, has been proved by the result of the case. The man, although in a condition so little hopeful at the time, rallied well from the shock of the operation. Some sloughing of part of the integument followed, but this has ceased, and the stump was in a promising condition, when suddenly acute tetanus set in. Under the latter disease, which must of course be deemed a mere accident, the poor fellow sank on the tenth day. At the consultation before the amputation, Mr. Lawrence had expressed a very decided opinion that the man would not live twenty-four hours if the limb were left on.

While giving the conclusion of this case, we may also allude to the further progress of another at the same Hospital, to which we referred last week. It is that of the inter-muscular hernia operated on by Mr. Lloyd. Although recorded in the *Mirror* of a contemporary of last week as having "succumbed," the man is (as we had stated) still doing remarkably well. He has, indeed, not had a bad symptom since the operation. Justice to ourselves and to those of our readers, who may chance to have read both journals for last week and noticed the extraordinary discrepancy, compels us to make this additional statement.

SUPPOSED ABSCESS OF THE LIVER.—PUNCTURE
ON TWO OCCASIONS.

(Under the care of Mr. LAWRENCE.)

A boy now under Mr. Lawrence's care in Henry VIII. ward at St. Bartholomew's is well worth a few minutes' attention from anyone who may have an opportunity of examining him. In his right subcostal region is a large evenly rounded prominence, easily visible to the naked eye, and in which fluctuation is tolerably distinct. There is neither redness of the overlying skin, nor tenderness or pain in the tumour. It is evidently continuous above with the liver. He does not look ill, though of clear skin, and somewhat delicate aspect. He is allowed to be up and about the liver, and eats his food with good appetite. His history of the swelling is, that he only noticed it about a week before his admission, which took place five weeks ago, and that there was then a good deal of pain about it. Three years ago, however, he received a blow on the part from falling on some planks, and after that he had for some weeks a good deal of aching there. His age is fourteen. On two occasions during the past fortnight Mr. Lawrence has punctured the tumour in its most prominent

part with a small trocar, and in each a few ounces of thin opaque yellow fluid were removed. No remains of hydatids were detected on either occasion. Mr. Lawrence stated in a consultation on the case last Saturday, that he thought the tumour was, at any rate, adherent to the abdominal parietes, and that he had it in prospect on the next occasion to make a freer opening into it. Whether it is an idiopathic abscess or a suppurated hydatid cyst, is still an open question.

THE FLEXION TREATMENT OF POPLITEAL
ANEURISM.

(Under the care of Mr. PAGET.)

The new method of treating popliteal aneurism by bending the knee and retaining it in that position, as adapted with success by Mr. Ernest Hart, and subsequently by Mr. Shaw, does not seem to have been productive of good results in the few cases in which it has as yet been tried in the London Hospitals. In a case under the care of Mr. Moore in the Middlesex Hospital the aneurism, which was an unusually large one, gave way into the joint during treatment by flexion. That the position mentioned might easily increase the liability to such an occurrence may readily be conceived, more especially when the aneurismal sac is placed on the articular aspect of the artery. Mr. Moore's patient, despite the formidable complication alluded to, made a good recovery after ligature of the femoral, and the effused blood was absorbed from the joint without causing any material irritation.

Mr. Paget has at the present time a case under treatment in Harley ward which bears some similarity to the above. Fortunately the joint has not become implicated; but there can be no question but that during the flexion treatment, which lasted only a few days, the aneurism enlarged, and that much irritation was set up around it. The patient is a fairly healthy man, aged 30, and the aneurism is situated in his left popliteal space. It had existed about five weeks, and was of large size when a fortnight ago he was admitted into the Hospital. So much increase in size of the tumour, tenderness about it, and swelling of the cellular tissue took place that the propriety of immediate ligature was discussed in consultation on Friday last. It was feared that the sac might be about to give way. It was decided to wait and watch the further progress of events. On Saturday Mr. Lawrence and Mr. Stanley again met Mr. Paget at the man's bedside. The condition of things was no worse in any respect than the day before, in fact, the pulsation seemed rather less. Mr. Paget remarked that he was loth to resort to the ligature prematurely, as in many of the cases in which the compression plan had succeeded consolidation had ensued unexpectedly after just such a blaze of irritation in and about the sac as was now taking place. He, therefore, preferred still to wait, having the tumour narrowly watched, and being prepared to ligature at once should the sac give way. Mr. Stanley supported this opinion, and it was adopted; although Mr. Lawrence, in whom the novel plans of compression and flexion treatment have as yet not obtained a convert, was in favour of immediate operation.

We shall revert to this case at another time.

SAMARITAN HOSPITAL.

THREE CASES OF OVARIOTOMY.

(Under the care of Mr. SPENCER WELLS.)

Case 1. OVARIAN TUMOUR—

ASCITES—OVARIOTOMY—SUCCESSFUL RESULT.

[From Notes by Mr. PHILLIPS, House Surgeon.]

R. W. aged 43, came from Dorking to consult Mr. Spencer Wells, and was admitted March 28, 1859.

History.—She has been married 20 years; has had eight children, seven of whom are living. Her mother is said to have died of ascites, but it might have been ovarian dropsy. Four years ago she was confined with her last child. During her pregnancy she had a great deal of pain in the left side. This disappeared after the labour, but her abdomen did not diminish in size as usual. On the contrary, it continued to increase gradually, but very slowly, until last September, when the increase became more rapid. It was not noticed to increase more on one side than the other, but extended centrally from below upwards. Since the more rapid increase she has lost health, strength, appetite and flesh. The

catamenia have been quite regular, but there was a greater quantity than usual last time.

Present State.—She is a large spare woman, of very sallow complexion, and the skin is blotched in brown patches, very much like "bronzed skin." Bowels regular; rapid, very feeble pulse. The appearance of the abdomen is well represented by the appended wood-cut, copied from a photograph taken by Dr. Wright, but some months later, just before operation.

The girth at the umbilicus was 53 inches, while the vertical measurement from ensiform cartilage to symphysis pubis was 28 inches. She had had an umbilical hernia long before the commencement of her present disease, and the skin at this spot was thin and transparent, being distended almost to bursting. Between the umbilicus and symphysis pubis the skin was raised by dilated and varicose lymphatics, presenting a very peculiar appearance. No solid tumour could be felt; but as fluctuation was very distinct all over the abdomen, though more distinct above and less below, and as percussion showed that the intestines were in the lumbar and hypochondriac regions, it was thought probable that an ovarian tumour was surrounded by ascitic fluid. Vaginal examination did not settle the question. The anterior wall of the vagina was somewhat depressed, but the uterus was moveable, and no solid tumour could be felt.

Progress of the case.—Partly because the skin at the umbilicus threatened to give way, and the patient was suffering greatly from distension—and partly to settle the diagnosis—Mr. Wells tapped the abdomen and removed six gallons of pale amber coloured highly albuminous serum. A moveable unattached ovarian tumour was then discovered, apparently about the size of a man's head.

She suffered a good deal from sickness and depression for some days after the tapping, but left the hospital on the 4th of April provided with an elastic belt and umbilical pad, with directions to return before the abdomen became as much distended as it had been.

She remained in the country until May 7, when she was readmitted. The girth at the umbilicus was then fifty-one inches, and the distance between ensiform cartilage and symphysis pubis twenty-eight inches. The catamenia had not appeared since she left the hospital, but they came on the day after she returned.

It now became a question whether ovariectomy should be performed at once, or whether an attempt should be made to lessen the shock of the operation by removing the ascitic fluid first, and the tumour a few days afterwards. After consultation, Mr. Wells decided on the latter course, and removed 49lb. 10 oz. of ascitic fluid on the 9th of May. Sickness, tympanitis, some pain, and rapid feeble pulse continued for ten days after the tapping, and it was not until the 24th of May that she was in a state sufficiently favourable for operation.

May 24.—*Operation* at 4.30 p.m.—Present, the hospital staff, with Drs. W. Webb, Greenhalgh, Westmacott, Davidson, R.N., Aitken, Mr. W. Adams, Mr. Knight, of Dorking, etc. Mr. Wells was anxious, if possible, to remove the tumour before much ascitic fluid escaped, in order that this

fluid might serve as a protection to the intestines from the air. Accordingly, as soon as the integuments were divided over the linea alba, from two inches above the umbilicus to about the same distance above the symphysis pubis, and some bleeding from superficial vessels had ceased, Dr. Routh pressed the tumour well forwards, as Mr. Wells rapidly laid the peritoneal cavity open throughout the whole extent of the incision. There were only one or two slight omental adhesions, and as soon as these were separated by the hand the tumour was easily removed. The pedicle was formed of the right Fallopian tube, and broad and round ligaments, and was so very short that the clamp used to secure it was placed close to the uterus. The tumour was removed by cutting away, leaving a portion of it projecting as a mushroom outside the clamp. Scarcely an ounce of blood was lost. The opposite ovary was found to be healthy. The wound was united by five harelip pins passed through the whole thickness of the abdominal parietes, including the peritoneum, which was perforated on each side at about a third of an inch from the divided edge. The needles perforated the skin on each side at about an inch from the divided edge. Superficial sutures of silver wire were introduced between each pin. The clamp and stump of pedicle were both kept outside on the abdomen, and the wound closed closely around. Not until the wound was nearly united was the ascitic fluid pressed out. The operation only occupied ten minutes. Lint was placed over the wound, and the abdomen supported by a flannel bandage. The tumour was a good specimen of the pseudo-colloid ovarian tumour, or compound ovarian cyst, and weighed ten pounds. The patient remained rather faint and very sick for about an hour, when she began to recover. A morphia suppository (one-third of a grain), was introduced at 6 p.m. A little brandy and water was given, and she began to feel better. At 10 p.m. as there was some pain, a second suppository was given.

First day after operation.—Vomiting continues troublesome, but she has had a fair night. Pulse, 98. Skin moist and warm. Tongue clean. No pain. Urine passed by catheter, scanty and high coloured. Six minims of hydrocyanic acid were given in an ounce of water, but it was soon thrown up. Effervescing draughts were given in the afternoon, but the sickness continued, and she kept nothing on the stomach all day. Still at night she was cheerful and without pain, and the urine increased in quantity.

Second day.—Pulse stronger than it was before the operation. Some inclination in the bowels to act. Going on well in all respects. There was some abdominal pain in the afternoon, and another suppository was given. Vomiting had continued, but she kept some tea and toast down this afternoon. At night there was sickness and faintness, with small feeble pulse, and anxious countenance; and small quantities of brandy and iced water were given at intervals through the night.

Third day.—Sickness continues; pulse 120, very feeble; she is very low and faint, and the skin covered with a cold clammy perspiration; breathing a good deal oppressed; urine scanty, and high-coloured. Finding the physical signs of a large accumulation of fluid in the peritoneal cavity, Mr. Wells removed the clamp, and after fixing the pedicle by a ligature, introduced his finger beside it, and thus gave exit to several pints of very fetid serum. She felt very much relieved after this. The sickness ceased two or three hours afterwards, and she kept down some cyder, to which she took a fancy, and some veal broth afterwards. The pulse ranged to-day between 140 and 130.

Fourth day.—Better all the morning, but in the afternoon she attempted to get to the night-chair—of course against orders—and was very much exhausted afterwards. She was faint, bedewed with cold perspiration, the hands and feet very cold, and the pulse almost imperceptible. Brandy was given freely, and she rallied. Then retching became very distressing, and a turpentine enema was given. This came away with some fæces, and a large amount of flatus. Rum and milk were afterwards injected into the rectum, and brandy was given every hour with water.

Fifth day.—She is rallying. Sickness ceased after some iced champagne which was given this morning. The harelip pins were removed, and the wound found well united deeply, though the edges of the skin had not united. There is still a considerable discharge of fetid serum from the lower portion of the wound, where the ligature on the remains of the pedicle passes. Six ounces of strong beef-tea, with half an

ounce of brandy were injected into the rectum three times to-day, and she drank a quart bottle of champagne. A large quantity of flatus passes *per anum*.

Sixth day.—Rather better all day; but is much troubled by flatulent distension of abdomen. An enema of two drachms of tincture of assafoetida, and half an ounce of turpentine in a pint of thin arrowroot, was given, which came away soon afterwards, followed by a great deal of flatus, and much relief. Pulse has ranged for the last three days from 120 to 130. The enemata of beef-tea and brandy were continued, and she took a pint of champagne daily.

Seventh day.—Pulse down to 108; urine more copious; abdomen much diminished in size. Beef-tea enemata and champagne as yesterday.

Second week.—During this week there was a gradual amendment, though sickness and flatulence were troublesome at times. The ligature came away with the sloughing stump of pedicle on the eighth day, when the superficial sutures were removed, with the exception of one. Pulse ranging from 108 to 96 until the *thirteenth day*, when it ran to 130 after a restless night. In the afternoon of this day there was a very large discharge of fetid pus from the opening left by the passage of the pedicle. She was low and heavy after this for some hours, and complained of cold feet; but some abdominal pain which had troubled her disappeared.

Third week.—This was a week of slow, but steady improvement. She began to take food with appetite; the bowels acted regularly; the pulse ranged from 120 to 100. The urine was passed in natural quantity; the discharge from the wound gradually ceased; she began to sit up; the opening where the pedicle passed very rapidly filled by granulation; she passed good nights, rapidly gained strength, and left the Hospital to return to Dorking by railway on the 20th of June, *twenty-seven days* after operation. She has been heard of since, and has gone on remarkably well.

Remarks.—One point of great practical interest in this case, namely, the propriety of removing ascitic fluid surrounding ovarian tumours as a preliminary step some days before ovariectomy, we shall refer to hereafter. Also to the plan of uniting the wound by including the peritoneum in the sutures. A third point of importance is the removal of the tumour while the peritoneal cavity is protected by the presence of the ascitic fluid. A fourth is the evacuation of the serum collecting in this cavity after the operation, by opening the wound. In a paper read last February at the Medico-Chirurgical Society, when commenting on the causes of death after ovariectomy, Mr. Wells said: "If with pain in the abdomen there were the physical signs of serous effusion, I would provide for the escape of this serum through some portion of the wound." He argued that this serum contains a morbid poison. It is very acrid. It makes the hands smart of any one whom it touches. Those inoculated by it are apt to suffer from morbid poisoning. If a medical man infected by it attend a woman in labour, that woman in all probability has puerperal peritonitis. "If then," Mr. Wells argued, "a patient can generate a poison capable of killing other people, may it not kill her? It is probably only formed by the inflamed portion of peritoneum, the other portions being quite capable of absorbing rapidly." Whatever may be thought of this hypothesis, it is very clear that in the case above narrated the practice so recommended was attended with the most marked success. The first evacuation of the serum was followed by immediate amendment, and some days afterwards alarming symptoms disappeared soon after the escape of some fetid pus. This was precisely what was observed in a case operated on by Mr. Wells, in February, 1858, when there was a very copious fetid sero-purulent discharge from the abdomen through the portion of wound kept open by the ligature on the peduncle. On two or three occasions when this opening became plugged accidentally, the patient complained of a good deal of pain and became feverish, but immediate relief was afforded by a free discharge of fluid after clearing the ligature.

Cases 2 & 3.—The report of this case has extended to such a length that we must defer until next week the report of another case of solid ovarian tumour surrounded by ascitic fluid, which was removed by Mr. Spencer Wells, in the Samaritan Hospital on June 17, and of a multilocular cyst, which was also removed by him on the 24th of June in the same Hospital.

HOSPITAL NOTES.

IRON-THREAD IN VESICO-VAGINAL FISTULÆ.

SINCE last autumn Professor Simpson has operated on fourteen cases of vesico-vaginal fistulæ. The last two are proceeding favourably in all respects, but the operation in them is too lately done to admit yet of perfect certainty as to the ultimate result. Out of the remaining twelve, in three the operation was only partially successful, and will require to be repeated a second time. In the remaining nine the fistulæ were closed by the first operation. Dr. Simpson has always used the common blue, annealed, iron-wire (No. 32 of the ironmonger's gauge) as his suture-thread. In his last six cases he has dispensed with the assistance of all clamps, buttons, or splints, and has merely brought together the vivified edges of the fistulæ, some of which were very large, with deep and closely-placed stitches of the iron-thread. All these six cases have proved successful. The two cases at present under treatment have been operated on in the same way.

THE PROVINCIAL

PRACTICE OF MEDICINE AND SURGERY.

STATISTICAL ANALYSIS OF 177 LITHOTOMY OPERATIONS.

At page 32 of our January number for the present year, we entered into a statistical analysis of the lithotomy operations performed in the different metropolitan (a) Hospitals during a period of three years and a-half. We now undertake a similar task as regards such of the larger of the Provincial Hospitals as have furnished us from time to time with the necessary data. In the present instance, the period included is from October, 1853, to December, 1858, or four years and a-quarter.

The following Provincial Hospitals have furnished the data which we are now about to analyse:—The Royal Berkshire (Reading), the Bradford, the Bristol General, the Canterbury, the Cheltenham General, the Cumberland (Carlisle), the Derby General, the Devon and Exeter, the Dorset County (Dorchester), the Dundee Royal Infirmary, the Durham, the Glasgow Royal, the Gloucester, the Huddersfield, the Hull, the Leeds, the Leicester General, the Liverpool Southern, and Toxteth, the Liverpool Royal, the Newcastle-upon-Tyne, the Nottingham, the Queen's (Birmingham), the Sheffield General, the South Staffordshire (Wolverhampton), the Staffordshire General (Stafford), the West Norfolk and Lynn (Lynn), the Winchester, York County.

The London list comprised a gross total of 186 cases, with 40 deaths; while the Provincial will show 175, with 22 deaths.

Before proceeding further, however, a few words of explanation are due to the reader as to the mode in which the facts to be analysed have been collected, and the degree of confidence which they claim. The data upon which our Quarterly Statistical Reports were founded, were furnished to us by the resident Medical officers of the different Institutions. The care and accuracy with which, in almost all instances, these statements had evidently been drawn up, enables us to rely confidently on their general correctness. It would, however, happen sometimes that owing to a change of House Surgeons or other accidental cause, the list of operations from one or other Hospital might for a certain quarter not be obtainable. Several of the Hospitals which during the first part of the period mentioned, furnished us with their operations, ceased to do so after a time, and were unavoidably on our part omitted from our list. These circumstances certainly go to some extent to diminish the value of the following summary. Still we have no reason whatever to doubt but that in each instance the whole of the operations performed in any single Hospital during the time that it proceeded to furnish us with them were duly supplied, and with-

(a) By an unfortunate error of the printer, the report alluded to was headed *Provincial*, instead of *London Practice of Medicine and Surgery*, and was preceded by the list of Provincial Hospitals.

out selection or omission. The periods referred to as having in some instances been omitted, did not probably differ in their rate of mortality from those which were included; at any rate, they were omitted for reasons wholly without regard to any such difference, if it existed. We believe, therefore, that although they may not be strictly and unexceptionably accurate, that the statements which follow will supply a very close approximation to the real statistics of Provincial Operative Surgery. At any rate, they will give the reader a far better idea of what that Surgery is, what its success, and what its fatality, than any other method within our reach. Before entering upon its examination, it now only remains for us to tender our best thanks, and those of the Profession at large, to the many gentlemen who without any selfish object, and in the pure love of science, have, at the cost of much labour to themselves, put it in our power to obtain such valuable deductions.

INFLUENCE OF THE PATIENT'S AGE ON HIS PROSPECT OF RECOVERY.

Age.	No.	Recovered.	Died.	Per centage of Deaths.	
1	1	1	0	'00	No death
2	9	8	1	11.10	1 death in 9
3	12	11	1	8.30	1 in 12
4	18	15	3	16.66	1 in 6
5 to 8	40	40	0	'00	All recovered
8 to 10	14	13	1	7.1	1 in 14
10 to 15	21	20	1	4.7	1 in 21
15 to 20	6	5	1	16.6	1 in 6
20 to 25	8	6	2	25.0	1 in 4
25 to 30	3	2	1	33.3	1 in 3
30 to 35	4	3	1	25.0	1 in 4
35 to 40	5	4	1	20.0	1 in 5
40 to 45	4	2	2	50.0	1 in 2
45 to 50	3	2	1	33.3	1 in 3
50 to 55	3	2	1	33.3	1 in 3
55 to 60	9	7	2	22.2	1 in 4½
60 to 65	8	7	1	12.5	1 in 8
65 to 70	6	4	2	33.3	1 in 3
70 to 75	1	1	0	'00	No death
75 to 80	2	2	0	'00	No death
Total.	177	155	22	12.3	

Thus it would appear that in the practice of our Provincial Hospitals the period of life in which the lowest death-rate after lithotomy prevails is between the ages of 5 and 10. Of fifty-five operations performed on patients between these ages all but one resulted in recovery. Children under the age of 5 do not appear to bear the operation so well as those a little older, since out of 41 operations we have 5 deaths. In the periods between the age of 10 years and puberty, and from the latter to 25, the mortality is much larger than in childhood, and it rises still higher during the twenty years next following, to decline, however, with further advancing age. The table before us differs from most other statistical statements on this subject, in showing a diminished ratio of death in the aged as compared with those in the middle period of life. The oldest three patients all recovered; and while out of sixteen operations performed on patients between the ages of 25 and 45, 5 ended in death, or nearly 1 in 3; out of 17, in which the subjects were between 60 and 80, the proportion was only 1 in 6. We shall at some future time show how remarkably this differs from what is found to be the case in London practice, and to offer some conjectures as to its explanation. In the meantime we will only remark, that lithotomy is practised with at least proportionate frequency in the provinces, and that it therefore is not the disturbing influence.

CAUSES OF DEATH.

We regret that we do not possess such detailed information on this head as was the case with the London operations, and that respecting several we have only been informed of the bare fact that death occurred. Under the head of "Cause of Death not Known," we shall therefore be compelled to include four out of the twenty-two cases. We have endeavoured to classify the remaining eighteen in the subjoined list according to the accident or lesion to which the fatal event appeared to be mainly attributable. In many, perhaps in most, more than one had been coincidently in action. Thus, in not a few in which the immediate cause of death was

pyæmia or abscesses about the bladder, hæmorrhage, which occurred at the time of the operation, appeared to have exerted an influence predisposing the patient to such lesions. The classification is, therefore, only an approximation to the truth, and must be so considered by our readers:—

Peritonitis	in 6 instances.
Abscesses about the bladder	" 4 "
Hæmorrhage	" 3 "
Pyæmia	" 2 "
Shock of the operation	" 2 "
Renal disease	" 2 "
Extravasation of urine	" 2 "
Exhaustion	" 2 "
Broncho-pneumonia	" 1 "

In this list several of the cases are counted under more than one head on account of several of the lesions mentioned having been combined.

RENAL DISEASE AS A CAUSE OF DEATH. (Two Cases.)

The cases in which death is directly assigned to renal disease are only two. In the first a man of 25, in very bad health at the time, died fifteen days after the operation, and both kidneys were found extensively diseased, one of them being a mere bag filled with fœtid pus. In the other the diagnosis was conjectural only: the patient, a man, aged 45, in tolerable health, had a small stone extracted (5ss) and sank comatose on the fifteenth day. The coma had existed during the two days preceding death, and there appeared good reason for considering it that of uræmic poisoning.

HEMORRHAGE AS A CAUSE OF DEATH. (Three Cases.)

In the first of these a very stout man, aged 55, had four calculi of moderate size removed. Secondary hæmorrhage occurred and made plugging necessary. Inflammation of the pelvic cellular tissue followed, and he sank exhausted on the 21st day. The subject of the second was a boy of 4, in good health. The hæmorrhage was immediate, and so profuse as to require plugging. Diarrhœa set in during the afternoon of the same day, and convulsions followed. Death took place on the third day, and at the autopsy there were evidences of infiltration of urine behind the bladder. In the third a worn down man of 44, had a large stone removed with unusually free bleeding, after which he sank exhausted on the fifth day.

SHOCK OF THE OPERATION. (Two Cases.)

The influence of chloroform as having possibly been injurious cannot escape attention in the following cases.

First Case (38), a boy, aged 4, in good health, had a stone the size of a marble removed by an easy operation. About twelve hours afterwards he began to suffer from vomiting, tympanitis, abdominal tenderness, and great depression, and these ended in death within thirty-six hours of the operation. At the autopsy no traces of peritonitis were found, and the condition of the parts proved that no unnecessary injuries had been inflicted in the operation. The bladder was congested. Second Case (39), a child of 2, in good health, died on the third day, having remained in a very sunken condition with much vomiting throughout. He had been half an hour under the influence of chloroform.

BRONCHITIS. (One Case.)

A man, aged 66, in good health, had two large stones removed, and sank under broncho-pneumonia a month afterwards. The wound was healing steadily. Before the operation he had been the subject of a fistula which was believed to communicate with the rectum.

PYÆMIA AS A CAUSE OF DEATH. (Two Cases.)

In the first of these (85) a healthy man, aged 48, had a calculus the size of a hen's egg, removed, and died two months afterwards, having been very low for some time before death. There were abscesses in both recti muscles, and in one psoas, and effusion into one pleural sac. The wound was not healed. In the second (129), a man of 63, sank on the tenth day. We have no particulars, excepting that "phlebitis was the cause of death."

PERITONITIS AS A CAUSE OF DEATH. (Six Cases.)

In one of these (17) a healthy man, aged 54, had a stone removed, weighing two ounces. Much difficulty was encountered, and the operation was prolonged. Death occurred at the end of a week. There was inflammation of the pelvic peritoneum, and an abscess over the left iliacus muscle. In the second (case 6), a boy, aged 8, died with all the symptoms of peritonitis forty-eight hours after the operation. The third closely resembled this: a healthy lad of 17 sinking on the second day, with indications of commencing peritonitis (83). In the fourth also, the fatal event rapidly followed the operation. In it the patient was a boy of 4, in fair health, who died of peritonitis on the third day. In the fifth, a stout man, aged 31, of intemperate habits, died of peritonitis on the fifth day after an operation, in which nothing unusual had occurred. The subject of the sixth (87), was a man, aged 56, in fair health, who had been submitted to lithotomy four times before. The fifth operation was a recto-urethral one, the stone being believed to be encysted. The cyst was incised, and the stone removed; but the man sank from peritonitis, complicated with purulent infiltration about the bladder, on the third day.

It will be remarked that none of these six patients appear to have been in bad health at the time of the operation; and three of them were under twenty years of age, two being young children.

PELVIC SUPPURATION AS A CAUSE OF DEATH. (Four Cases.)

Two of these (cases 17 and 87) have already been mentioned under the head of Peritonitis, and a third (case 63) under that of Hæmorrhage. In the fourth, an unhealthy lad, aged 12, had a moderate sized lithic acid stone removed, and died on the eighth day. An abscess was found between the rectum and the bladder, and there was also pelvic peritonitis.

In all these peritonitis of pelvic serous membrane co-existed with the abscess.

EXHAUSTION. (Two Cases.)

The first of these (case 63) is already mentioned in the list of Hæmorrhage cases. The subject of the second was a man, aged 65, in fair health at the time, but who, without any specific ill symptoms, sank into a feeble state after the operation. Death took place in the eighth week. Four calculi had been removed, weighing together about an ounce.

EXTRAVASATION OF URINE.

Case 86, the first of these, has been alluded to under Hæmorrhage. In the second, a florid and healthy man, aged 37, sank thirty-six hours after the operation. Commencing peritonitis, and extravasation of urine, are stated to have been found.

NOTES AND QUERIES.

He that questioneth much shall learn much.—Bacon.

No. 345.—DRESS OF PHYSICIANS.

"We are bound to declare, and do so with infinite pleasure, that the members of the Medical Profession are, take them all in all, patterns of neatness and accuracy in their dress. They are ten times better clad than the clergy, who in Scotland, at least, exhibit an almost superstitious reverence for the precept of taking no thought as to their raiment. They are more scrupulous in their attire than the lawyers. . . A sloven by the side of a sick bed looks like the forerunner of Azrael; whereas a well-dressed, trim, and gentlemanly Medico, entering the chamber like a sunbeam, carries with him a mesmeric influence, which, better than pill or potion, allays the fever of the patient. In the days of Abernethy, roughness was considered a Medical virtue; courtesy was branded as hypocrisy. Poets, who have shown themselves from the beginning of time the best judges of propriety, invariably represent eminent Medical men as patterns of mundane neatness. Podalirius and Machaon—Physicians both—are the only men noticed in the Iliad who inspire us with the idea of uniform tidiness, and strict propriety of apparel.

Throughout the whole Trojan war, they dressed like gentlemen, maintained the dignity of the order, and doubtless, as they were not salaried, picked up an infinity of fees, to which they were most justly entitled."—*Blackwood*.

No. 346.—TEA.

SIR,—In an old newspaper (a fac-simile of which I possess) entitled the *Commonwealth Mercury*, published in September 1658, I find the two following advertisements, which, perhaps, may be curious enough for a place in "Notes and Queries."

H. L. MAYSMOR.

Springfield-lodge, Park-vill. east, Regent's-park.

"That excellent, and by all Physicians approved, China Drink, called by the Chineans, Tcha, by other nations Tay or Tee, is sold at the Sultaness-head, a cophee-house in Sweeting's-rents, by the Royal Exchange, London."

"Whosoever desireth to be cured of a Rupture or Broken Belly, of any ages to threescore and ten, let them repair to one Rowland Pippin, who will by God's help make them whole; the poor for charity, the mean for little, the rich for reasonable terms. He will stand to all charge for the cure until they shall finde by experience their own good. He hath taken a chamber in the Strand, at the Three Pigeons, near Somerset-house, where you may finde him all the Fore-noons until nine of the clock, and from one to five in the afternoon. He lives in the country at Sutton-brewhouse, near Gilford in Surrey; his Father, Brother, and himself have used this practise this threescore years in the west, where the name of Pippin is remarkable for several cures of this nature."

No. 347.—REMEDY FOR JAUNDICE.

"I scarcely know whether ears polite will tolerate the record of a sovereign remedy for jaundice, which fell under my notice in a parish in Dorsetshire a few weeks since, but which I find upon inquiry to be generally known and practised in the neighbourhood. The patient is made to eat *nine lice* on a piece of bread and butter. In the case referred to, I am bound to state for the credit of the parish, that the animalcules were somewhat difficult of attainment; but that, after having been duly collected by the indefatigable labours of the village doctress, they were administered with the most perfect success."

No. 348.—IS THERE NO WAY OF RADICALLY DESTROYING ASCARIDES?

SIR,—An interesting discussion has lately taken place in the Academy of Medicine of Paris, respecting the best remedies for the cure of persons affected with ascarides in the rectum. The subject is one which I venture to think deserves more attention than is usually accorded to it; and for the reason that, in a very great number of cases, the treatment hitherto employed for their destruction appears to be incapable of entirely eradicating these creatures. Küchenmeister seems to admit that their extirpation is impossible; he tells us that he himself has long suffered from their presence in his own person, and has not been able to free himself from them. Dr. Watson relates incurable cases; most observers, also, have probably met with cases in which their efforts at a perfect cure were unavailing. Such a conclusion, also, I regret to say, seems to be what their experience has brought our French brethren to on this subject. Now really it does seem hard to think that our art is unable to cope with these wretched creatures; and especially so, when we reflect upon the actual misery which their presence often causes. Will you, therefore, allow me, through your Journal, to ask of others the benefit of their therapeutical experience in the cure of this affection? The experience of Dr. Hervieux leads him to this conclusion: That castor-oil and simple daily glysters are the only useful remedies known to us at the present moment. He considers the affection incurable. So also does Dr. Blacke; and he relates a number of cases, in all of which the art of Medicine failed to cure. One was the case of "a fashionable lady, remarkable for her beauty, in whom every kind of treatment failed. When she went into society, she was forced to sit on cool, unstuffed chairs, in order to diminish the painful sensations caused by the ascarides." Dr. Legroux was convinced that mercurial ointment dissolved in water, and given as a glyster, would destroy these animals; he had used such an injection in cases where he had in vain used all other remedies; he did not, moreover, mean to assert that the ointment was a specific. Such were some of the

opinions given on the occasion referred to in the French Academy. I think that whoever would give a satisfactory answer to the following questions would confer a great boon on the community:—How high up in the intestinal canal do ascarides live and breed? What injections will kill the animals without injuring the intestine? Do the injections which destroy the animals, also destroy their ova? Is there any proof that these animals reside higher up in the intestine than injections will reach? Why do they come down towards the anus, especially at night and in the evening?

SATURDAY, JULY 2.

RUCK versus STILWELL.

THE verdict of the jury in this case has placed all medical men who practise in Lunacy in a very unsafe position. Large damages have been given for what has been called "false imprisonment" where there has been no imprisonment, but simply the detention of a dangerous lunatic until his malady abated, time not having been given to ascertain his real recovery. The case was made to turn, not on the patient's state of mind when in the asylum, but on the supposed partnership of one of those who signed the Medical certificates with the asylum in which the patient seems to have recovered; and yet, unless the meaning of English words is wholly changed, there was no partnership existing, nor any engagement resembling a partnership.

Mr. Ruck, a man of property, after being in an unsettled state, bordering on mental derangement, for about two years, became intemperate, disposed to wander about without reasonable object, took extravagant views of the value of his estates, and fancied he heard voices informing him of his wife's notorious infidelity, not with one person, but with many persons casually met in travelling or anywhere; without affecting decency or even concealment. He expressed these suspicions in the grossest terms; and imagined that a friend who tried to persuade him of the wrong he was doing to his wife had some interested object in view, and drugged the wine placed before him. He left his friend's house in this wild state, to go nobody knew whither; and as, still influenced by the imaginary voices, he was in the habit of carrying loaded pistols with him, he was very properly secured. In these circumstances, his wife, instead of waiting until he murdered her or somebody else, resorted, after much patient suffering, to the advice of Medical men; and, on the Certificates of Dr. Conolly, of Hanwell, and Mr. Barnett, of Reading, signed an order for his admission into the excellent asylum called Moorcroft-house, near Uxbridge; where the judicious, and liberal, and kind treatment pursued by Dr. Stilwell, soon induced comparative tranquillity. Dr. Conolly saw him, and

conversed with him occasionally. Although not violent, Mr. Ruck still for some months heard voices, and he still cherished his monstrous delusions, and expressed them in foul words. For a time, in the eighth month of his residence in the asylum, he appeared to be becoming less calm when alluding to these delusions; but in the ninth month he discontinued conversing upon them at all, and shunned conversation with those about him; but he never disavowed them, or expressed regret for the cruel wrongs done to his wife. Neither to Dr. Stilwell, nor to Mr. James Stilwell, the regular Medical attendant, nor to Dr. Conolly, with whom he had several opportunities of speaking, did he say one word expressive of his having recovered his reasonable senses. But at this time his attorney took him to various medical men, to whom, and to whom alone, Mr. Ruck professed that his delusions had left him. These medical men declared that the case had been one of delirium tremens, and ought never to have been sent to an Asylum. They gave a positive opinion of the early symptoms, which they had not seen; and thus exhibited to the public one of those scenes which conflicting Doctors too often and far too eagerly act in. Consequently, on a petition for a commission in lunacy, intended to secure the patient's wife and children the means of subsistence, the jury found that Mr. Ruck was sane: they were far from unanimous on the point; but there was a majority in favour of that opinion.

After this decision, Mr. Ruck has never expressed sorrow for his insane and cruel aspersions on his wife; has not lived with her; has disregarded both her and her children, and scarcely allowed her any money to support herself or them; pursuing, indeed, a line of conduct only consistent with the supposition of his mind continuing to be unsound.

Ten months afterward, an action is brought against Dr. Stilwell for false imprisonment. The previous insanity, and the nature of it, are not denied; the treatment of the patient in the Asylum is not impugned; and the whole cause is made to turn on the assertion that Dr. Conolly, who signed one of the Medical certificates, was a partner in Moorcroft-house.

What are the facts respecting this asserted partnership? We believe them to be simply these. Dr. Conolly was the intimate friend of the late Dr. Arthur Stilwell, the proprietor of Moorcroft; he was gratified to find, several years ago—and when private asylums were far from being what they now are—an establishment in which there was everything conducive to the mental and physical recovery of gentlemen afflicted with insanity; a spacious and cheerful house, extensive grounds, social enjoyments, and kind and enlightened superintendence. From that time he recommended patients of that class to be placed under Dr. Arthur Stilwell's care. When a Physician practising exclusively in cases of nervous disorder is consulted about an insane patient, his duty is not limited to prescribing pills and draughts, or to any mere Medical treatment. The patient's recovery requires these things carefully to be considered; but it also requires moral treatment, management, protection, security by night and day, and the regulation of all the habits of the patient's life, often for many months; and this is in many cases impracticable, except in a good asylum. To carry the plan into effect, and to the satisfaction of the patient's friends, the Physician who is consulted, if practising in cases of lunacy, and who recommends the asylum he prefers, is, in almost every instance, expected to see the patient from time to time during his residence in the asylum; and for these visits, and for the responsibility he incurs, he must, of course, be in some way or other compensated. At Moorcroft, during Dr. A. Stilwell's life, Dr. Conolly was paid, when such circumstances arose, by the proprietor of the asylum; to the great benefit, even in a pecuniary sense, of the friends of the patient. This arrangement has continued to exist between Dr. Conolly and the present Dr. Stilwell. At the time Mr. Ruck was at Moorcroft, nearly forty patients were in the esta-

blishment; of whom fifteen or eighteen had been sent thither by Dr. Conolly, and for seeing these he received the moderate sums which have been so needlessly disclosed to the public. The statement of these payments merely showed that the proprietors of Moorcroft, far from making a bargain with Dr. Conolly to attend his patients, when under their care, at so much per head, liberally paid him in relation to the payments which could be afforded by the friends of each patient: and even this was a mere *honorarium*, for which Dr. Conolly could make no legal claim; and which did not make him accountable for any of the expenses of the Moorcroft establishment. But in a Court of Law all these facts easily become distorted. Jurors whose education scarcely qualifies them for being judges except of mere money transactions, and a barrister eager for the plaudits of common auditors, can thus inflict great injustice; and truth is trampled under foot. The remedy of these things will, however, surely come. Medical men will even now scarcely venture to sign certificates of insanity. Patients temporarily recovered, although known to be dangerous, are every week liberated from asylums. Two or three horrible murders have been already the result; and many more may be expected. In the streets, in the parks, in the theatres, at the gates of our palaces, may now be seen, too often, these people of dangerous impulses, inconsistent with the safety of their neighbours.

The temptation offered to the public press by these lunacy cases is usually productive of comments which, however exaggerated, or even unjust, are welcomed by many readers. For a time, truth is still lost sight of and overshadowed, and a well-earned reputation may be destroyed in a day. Against such danger there is no protection; and those assailed can only bow awhile to the storm, relying on the eventual ascendency of justice. The triumphant injustice established by the verdict of the case of Ruck will, doubtless, for some brief space, furnish a subject for popular commentary not very gratifying to the many honourable men who devote themselves to a difficult and important, and most anxious branch of professional study and duty. Dr. Stilwell must patiently submit to hear his most comfortable house, with all its generous arrangements, stigmatised as a prison; and Dr. Conolly must as patiently read imputations upon him, implying the enormity of receiving remuneration for his medical services.

THE WEEK.

At the moment of going to press we receive a copy of correspondence (which we shall publish entire next week) between some Practitioners of Southampton (Drs. Lake, Scott, and Aldridge), Dr. Christison and Dr. Hawkins the Medical Registrar, respecting the right of ungraduated Licentiates of a College of Physicians to assume the title of Doctor. Dr. Hawkins says:—"I do not designate a Licentiate, as above described, as M.D. in the Register, or in any certified copy of the register;" and again states officially his direction that "in letters and receipts sent from this office, no person shall be addressed as Doctor who has not taken the degree of M.D."

Lord Clyde reports to the Governor-General of India on the conclusion of the military operations which ensued on the great mutiny, that the Medical Department—

"being composed of officers belonging to the two services, has shone equally in the matters of general organisation and of regimental arrangements. The Director-General, Dr. Forsyth, and the Inspector-General of Her Majesty's forces, Dr. Linton, C.B. in Calcutta, have worked successfully to meet the great requirements made on them; and the staff and regimental Medical officers have well maintained the credit of their noble profession, and the reputation for self-

sacrifice which belongs to the surgeons of Her Majesty's armies—a reputation which is maintained in the field on all occasions, as well as in the most trying circumstances of the Hospital;"—

Hereupon Lord Canning "desires to express" to Drs. Forsyth and Linton, and to all the officers of the Medical Department "who have been employed in the field, or who have elsewhere furthered the service by their exertions in providing for the welfare and the wants of the troops, the cordial acknowledgments of the Government of India for the important services they have rendered." Whether these officers will receive more substantial marks of favour than "cordial acknowledgments" remains to be seen. After a celebrated cavalry charge not quite out of recollection, said to have been "ordered by a fool and led by a madman," both the commander and the leader were decorated with the highest military honours. Had Medical men proved equally good officers, a court-martial would have been the inevitable result. When they do their work so well as to elicit the thanks of the Commander-in-Chief, it seems rather hard to be satisfied with the "cordial acknowledgments" even of a Governor-General.

Ophthalmic Hospitals appear to be very rare in France and in Germany. The speciality, however, of Optical Surgery is waking up in Germany. It is announced, as something like an event, that in accordance with a decision of the Minister of Instruction, a new service, specially devoted to diseases of the eye, has been established at Berlin, in the Hôpital de la Charité. M. Græfe is the head Doctor of it. Hitherto, this celebrated ophthalmologist (the word is not ours) has only been able to take under his charge a very few individuals at a private establishment. "All the world may now go and profit of his learned instruction."

Watters and Edwards, two of the gang of advertising aurists, have been fully committed for trial. At the final inquiry, before Mr. Norton, it appeared that the prisoner Watters had, as far back as about the year 1833, pleaded guilty to a charge of arson, and was sentenced to eighteen months' imprisonment, and subsequently to that, had been tried, convicted, and sentenced to three years' imprisonment for personating other persons at the College of Surgeons. Edwards's history is, that he was brought up as a druggist. His connexion with the Bennett gang is made out by his own evidence on the trial of the solicitor, Haynes, at the Old Bailey, last April. Edwards said:—

"I live at 28, North-street, Limehouse. I was in the employment of Messrs. Bennett Brothers, of 32, Spring-gardens; they carried on the business of aurists. I know the defendant Haynes. I have frequently seen him at 32, Spring-gardens. I was assistant to compound the medicine, and gave it to the patients. I know the composition of the medicine well—there were five compositions, eardrops, embrocation, injection, fumigation, and tincture. This bottle contains the embrocation, and this the injection; this is urine; they are all the same, differently coloured. The fumigation has no oil in it—the others have oil; this one is train-oil (what they call cabbage-oil), and urine. This red mixture is a solution of cochineal and urine. The urine extracts the colour from the cochineal; this one is drops for the ear. Two or three of these went together, and they were charged from 1s. to £2, £3, and £4,—it depended on the patients. We had a great many patients; I should imagine twenty or thirty a-day. I kept the books and made entries. I have not the books with me. The profit was at least £2000 for each of the two brothers Bennett."

Sufficient evidence was adduced to ensure the committal of the prisoners, and they will have to take their trial on the charge of conspiracy to obtain money from different witnesses by gross fraud. It appears that since the recent inquiry urine

has not been thought quite so efficient a remedy for deafness as before; the quacks, according to Mr. Rodgers, having taken to the use of solutions of sulphate of zinc, acetate of lead, and spirit of lavender. On the part of the prosecution, a Mr. Samuel Evans Smith, *Surgeon to the National Ear Institution*, in Pall Mall East, was called. Whether this National Ear Institution is some offshoot or not of one of the defunct Infirmarys did not appear; but we may probably hear more of this by-and-by. In the meantime we are glad to see the general press taking a more rational tone than heretofore on these matters. It is no longer the fashion to decry the profession, and exclaim against Medical jealousy; but it is acknowledged that the public must be protected against the fraudulent conspiracies of quacks and impostors. Witness the following passage which concluded an able leading article in the *Daily Telegraph* :—

“When Signor Dulcamara, in his red coat and top-boots, and in his chaise with the piebald pony, and the man with the Roman helmet beating the big drum behind, makes his appearance in a country village, we know and expect the voluble scamp to be a humbug, and are satisfied that he will be only enabled to force the sale of his mendacious ‘Elixir’ by appealing to the vanity and folly of his hearers. When Kattafelto, ‘his hair on end, wondering at his own wonders,’ mounts the platform, with Jack Pudding tumbling and jesting by his side, we look forward only to so much lying and swindling, and are content to know that we have been at least cozened out of our deniers in an amusing manner. But these quacks of modern times, with their diplomas, their white neckcloths, their solemn advertisements, their grand houses, and their livery servants, are far more dangerous impostors. The aged, the youthful, the credulous and inexperienced of the middle classes,—nay, even the valetudinarian rich—become their ready dupes and easy prey. Of Quacks in general, the majority are mere shallow sharpers and holders of sham testimonials; but among them there are, we grieve to say, some accredited and certificated persons—the black sheep of their Profession, who make use of their position for the vilest and most dangerous purposes. It is, then, the duty of the administrators of the law to root out and punish these shameful impostors, while it behoves the governing bodies of the Medical Profession to search for the few quacks who take shelter behind, and are a disgrace to, their diplomas, and expel them with ignominy from the ranks of the Profession whose name they have abused.”

The annual election of Fellows of the Royal College of Physicians of London, which was to have taken place last Saturday, has been postponed for the present. The remarks made upon the selected list of proposed Fellows by an old Licentiate in our last Number, seem (we may therefore conclude) to have been not untruly founded. The list evidently requires reconsideration. Perhaps some measure of expansion, perhaps some of condensation, will render it a more satisfactory document than it appears to have been considered by the Fellows. As far as we can learn from those particularly interested in this matter, we gather that many of the old Licentiates consider themselves, and are considered by the Fellows, to have been unfairly passed over on this occasion, and that the privilege of selecting Fellows out of the list of recently made Licentiates has not been exercised with sufficient caution. We have been favoured with a sight of the names of the proposed Fellows, and on comparing it with a list of the old Licentiates of the College we are bound to say, that we think there is a show of reason in these complaints. We find in the list, it is true, the names of some recently made Licentiates who are every way deserving of being at once made Fellows; but it is evident, that the very great privilege of election to the Fellowship of gentlemen from that class of Licentiates, was never meant to be exercised, except in some very striking and prominent instances; and most assuredly (as we said last week)

in no instance so long as the claims of any of the old Licentiates were superior to, or even simply equal to, those of the newly-made class of Licentiates. We cannot but think that the College would act wisely in at once electing to the Fellowship, out of their list of old Licentiates, every gentleman who is fairly worthy of the honour. When this is done, then the ground will be properly broken for a more extended consideration of the claims to the Fellowship of the recently-made Licentiates. The task which the *concordarii* have to perform in this matter is certainly not an easy nor a pleasant one; and we can well understand how difficult it must be, in a case of this kind, to satisfy every one. We will, therefore, venture to throw out a hint, the adoption of which would, we believe, greatly assist the *concordarii*, and at the same time satisfy the body of the Fellows at large. Why should not each Fellow suggest, in writing, to the Council of the College the names of gentlemen he considers to have claims to the honour of the Fellowship? It is very evident, that the most scrupulous Council in the world can scarcely help passing over, unwittingly, certain individuals, who are, nevertheless, most highly honourable and deserving men. The adoption of the plan we propose would, we believe, bring before the Council the claims of all, and satisfy the desires of the body of Fellows.

An attempt has been made, which we are happy to say has proved unsuccessful, to reduce the salary of the Medical Officers of Health, of St. George's, Hanover-square, Drs. Aldis and Drutt. A special Vestry was called last week to consider this question, when the Hon. C. S. Vereker moved that the present salaries of £250 a-year each should be reduced to £100 each. This absurd proposition was seconded by a Dr. Appleton, of whom we now hear for the first time; but who we find from the Directory, is returned as an M.D. of Pisa, M.R.C.S., Eng., and L.S.A., 1839, residing at 48, Curzon-street. Mr. Peat moved as an amendment, that the subject be referred to the “Nuisances and Diseases Prevention Committee.” But this amendment was lost. Mr. W. F. Cowper, M.P., suggested that one Medical officer might be sufficient for the parish. The Medical officers were defended by several speakers, and the motion for reduction of their salaries was lost by a vote of 38 against 13. A similar attempt of the Board of St. Luke's, Chelsea, has been as happily defeated. This recognition of the value of sanitary science by the public is very gratifying.

DURATION OF LIFE IN THE PROFESSIONS.—In summarizing the results of the whole of the communications which had been read to the Statistical Society at different periods, Dr. Guy has been able to base his conclusions on the large number of 8449 facts. From these he had drawn the following inferences:—1. That the value of human life was lower in the seventeenth century than in the sixteenth; but that it experienced a marked recovery in the eighteenth; and that this remarkable feature was incidental to each class of the community, with the exception of sovereigns, Medical men, artists (who show a progressive improvement), and lawyers (who show a progressive deterioration). 2. That the duration of life of married men is greater than that of unmarried men—the difference being five and three quarter years in favour of the former. 3. That, as regards the comparative duration of life of the two sexes, females have the advantage over males, and a better expectation of life at every age from 25 to 75.

M. SCRIVE, Physician-in-Chief of the Army in the East, relates, that the necessities of war required that 309,268 soldiers should be sent to the East. Of these, 200,000 entered the ambulances of the hospitals for treatment; 50,000 for wounds, and 150,000 for diseases of different kinds. Two sick men out of every three of men in the prime of life and vigour of body! Proving the old tale, that armies perish through diseases, not from the fire of the enemy.

REVIEWS.

Cyclopædia of Anatomy and Physiology. Edited by ROBERT B. TODD, M.D. F.R.S. etc. Six vols. large 8vo, pp. 5350. Illustrated with 2853 woodcuts. London: 1859.

TWENTY-FOUR years ago Dr. Todd made public an original and ambitious plan, by which he proposed to place the natural sciences of Anatomy and Physiology in the most varied and extensive aspects in which they could be regarded by the scientific world; and at the same time to develop as fully as possible the practical usefulness of those sciences in every field of study. We have now great pleasure in being able to congratulate the learned editor on so successful a completion of his most laborious undertaking. When it is remembered that in his original address, Dr. Todd distinctly stated that his work "is intended to embrace the whole of the sciences of Anatomy and Physiology, these terms being used in their largest sense, as far as regards the animal;" and when we know that the age in which this work has been carried through the press has been one of unprecedented activity in the cultivation of every branch of natural science, we must regard the completion of this gigantic work as a most valuable boon to the literary and scientific world. It shows at once what has been done during the time in which it has been passing through the press. Thus far, it will ever be of great value, in the history of the progress of Medicine as a science, as well as of the natural sciences generally.

We doubt if Dr. Todd originally contemplated so large a work; but, starting, as he did, in the right direction, he soon found himself in the midst of a mighty stream of science, whose numerous tributaries, while they increased the volume of the stream, gave strength to the current by which he was borne along. Once in the great current of this flowing stream, he was borne safely and surely onward; and now he has the undisputed merit of having steered a most unwieldy ship to the wished-for haven, manned as it was by a crew of ninety-two men, more or less eminent in science—a crew, we know, to be not of the most manageable description, when embarked together on the great ocean of literary labour. During this long period of twenty-four years, we have to regret the loss by death of many an able and willing hand, who cheerfully shared in the labour of this great work. The names of Babington, Bostock, Brennan, Dodd, Dutrochet, Edwards, Marshall Hall, Robert Harrison, Malyne, George Newport, John Reid, Forbes Royle, Henry Searle, and William Trew, compose this lamented list.

The period during which the work before us was written is characterised by the greatest activity and energy of original research, more especially in the direction of Organic Chemistry, Experimental Physiology, Comparative Anatomy, Embryology, Development, and Histology. The interesting topics of the work, the original goodness of the plan, and the adaptability of the scheme to the exigencies of the age—the splendid array of talent which the Editor has been able to bring together in the construction of the work, the knowledge, the energy, and the industry of the Editor himself, and lastly, the elegant manner in which this work has been got up, all contribute to make the *Cyclopædia of Anatomy and Physiology* a work which merits the confidence of the scientific world.

Anatomy in its most varied form and most extensive range is the basis or groundwork of the volumes before us. Upon such a comprehensive range of anatomical knowledge, every branch of scientific inquiry relating to Physiology must find a sure foundation; while on such a broad and sure foundation the science of Medicine itself is being built up, it may be by slow degrees, but certainly with the most rational hopes of ultimate success. Thus by the co-operation of many labourers, each exploring his own favourite region, and expounding his chosen theme, a faithful record has been given of the present state and recent advances of anatomical and physiological knowledge in all those directions which we have just indicated. The work before us is indeed made up of a series of monographs from a number of contributors, embracing "nearly all the most distinguished cultivators of physiological science in the present age"—men whose labours have caused the science of Physiology to rise up out of a collection of vague and ill-founded hypotheses—from crude and undigested facts to the rank of an intelligible and attractive science.

The following is a brief statement of the general scheme of the work, sufficient to show its comprehensive character:—It includes the descriptive anatomy of man, a sketch of every individual member and organ of the human body; the topographical or surgical anatomy of man, denoting the parts, boundaries, and relations of those regions of the human body which most frequently become, through accident or disease, the seat of surgical operations; the department of anatomy termed "general" or "physiological," in which are examined the particular tissues by which individual members and organs are built up. It is in this department of anatomy that the greatest changes have been made through the comparatively modern use of the microscope, and through the investigations of chemists. Not restricted, however, to the anatomy of man, this work embraces also descriptions of the structure of the various classes of the animal kingdom; of the several systems of organs traced throughout these classes, from the lowest to the highest, through all their modifications—constituting the science of "Comparative Anatomy." Under the title of "Physiology," this work offers a series of elaborate essays on the functions which distinguish organisation, both in the animal and vegetable kingdoms—in which, moreover, are taught the modes by which we live, and move, and have our being. Lastly, an account of the chemical composition of animal and vegetable structures, together with the properties and attributes of their varied constituents.

Many of the topics, from their very nature, preclude the possibility of much original matter being written regarding them (such as the articles on simple Human Anatomy); but they have all the merit of being careful and judicious digests of the state of our knowledge up to the period at which they have been written. On the other hand, again, we have numerous articles which imply almost a lifetime of research, and which teem with the records of original observations.

Altogether, the work deserves our best wishes for its success.

On the Hygienic Management of Infants and Children. London: 1859. 8vo, pp. 115.

In his preface, Dr. Barker introduces as his apology for writing, the poet's symbol

"Just as the twig is bent, the tree's inclined."

This is the key-note of the whole treatise. Dr. Barker divides his book into the following sections:—Mortality of Infancy; Diet; Clothing; Temperature; Air; Sleep; Bathing; Light; Exercise and Amusements; Nursing and Nurseries; Vaccination; Dentition; Education. Each of these subjects has its separate chapter, and is treated of in a manner which is at once scientific and simple. Few men have the faculty of writing a popular work, which is not also flavoured with a strong dose of charlatanic salt. Dr. Barker's book is an entire exception to this too common rule. The science is, as would be expected from the author, sound,—the language pleasant, if not eloquent,—the intention excellent. Dr. Barker would extend the domain of the Physician to an extent not generally recognised as yet. It is not, he thinks—and in this we entirely agree with him—the mere duty of the learned Doctor to stand by the sick bed, and write the prescription. He must look to the earlier developments of human maladies, and waylay diseases while the threatened are in safety.

We heartily recommend the perusal of this book to all our readers. It is a book they can read for themselves with advantage, and lend to their patients with security.

AT NOVARA there are two large, airy hospitals, one civil and the other military. All the ladies of the place, without exception of rank or position, have offered their service to the surgeons as nurses, and their conduct is stated to be admirable. They may be seen with white aprons and tucked-up sleeves, comforting and relieving the sufferers.

"M. RICORD, the champion in the great struggle of 1852, has declared that the transmission of secondary syphilis, congenital or acquired, appears to him to be now demonstrated. His explanations, his commentaries justifying his previous opinions, his reproval of confusion in the ideas of others—all this is only a cry of grief excited by the effort of the sacrifice."—*L'Union Méd.*

PROGRESS OF MEDICAL SCIENCE.

Selections from Foreign Journals.

CASE OF SPINA BIFIDA TREATED BY COLLODION.

(By Dr. BEHREND.)

A strong healthy child was brought to Dr. Behrend when seven weeks old, having a swelling over the last lumbar vertebra and the upper part of the sacrum. It was the size of a small orange, of a roundish form with a broad base, and disappeared under pressure of the finger. The skin over it was very delicate, transparent, and of a palish red. Pressure which caused the disappearance of the fluid seemed to give the child pain, and induced distortion of the features, which disappeared when this was removed. The aperture in the vertebra could be distinctly felt. The author resolved to try the effect of compression by collodion; and in order that its action should not be too suddenly energetic, he mixed it with some castor-oil in the proportion of three parts to six of collodion. On July 2 the whole of the surface of the tumour and some distance beyond were painted with this. No bandage was applied, and the parts were left freely exposed to the air for an hour and a-half, a firm but yet soft and yielding covering having formed over the tumour. Some wadding and sticking-plaster were now applied. Next day some amount of contraction was thought to have taken place, and a pencilling with 8 parts of collodion to 2 of castor-oil was performed. By the 7th of July a remarkable degree of contraction of the tumour had taken place, and it was painted with pure collodion. On the 8th there was a slight rupture observed in the shrivelled wall of the tumour, and some moisture issued; but on close examination it was believed that the rupture only implicated the layer of the collodion, and did not penetrate within the tumour. This had now diminished to the size of a filbert, and became much flattened. A small plate of caoutchouc, wrapped in muslin, was laid over it and kept on by a roller. This was kept on for three weeks, when nothing else was visible than the thick skin, stretched tightly over the aperture in the spine, and from which the collodion had long since become separated. The plate was directed to be worn some time longer yet, and the child when seen October 12, seemed well and hearty, and fully developed—the large fontanelle, which had been too open, having become diminished in size. No trace of the tumour was visible, some thickened skin and a subcutaneous mass of almost cartilaginous hardness supplying its place, allowing the edges of the bony aperture only to be very imperfectly felt. The author thinks that probably the collodion might have been used at once without the castor-oil, when its influence would have been more powerful; and he suggests, under certain circumstances, the combination of lead or tannin with it, in order to produce a more immediate effect on the wall of the tumour. In the present case he considers that some calomel which, together with cold applications to the head, were employed on account of a head affection which threatened to come on during the treatment, may have contributed to the rapid absorption of the fluid.—*Journal für Kinderkr.* Band. xxxi. p. 400.

EXCERPTA MINORA.

The Prone Position in Obstetric Auscultation.—Professor Byford states that the foetal heart may be heard several weeks sooner by placing the woman on her face, with the head lower down than the level of the feet, and the abdomen hanging freely down from the spinal column. The uterus by its weight keeps in close proximity to the anterior wall of the abdomen, and the end of the stethoscope can be brought nearer to the foetal heart than in any other position that can be assumed.—*American Med. Chir. Rev.*, May, p. 520.

Labour with a Large Child.—This is the largest child recorded in Philadelphia obstetric annals, weighing as it did sixteen pounds. Dr. Ramsbotham is recorded to have delivered a woman of a child weighing sixteen and a-half pounds, and Mr. Bloxam relates a case of forceps delivery, in which the child weighed seventeen pounds and twelve ounces,

and whose length was twenty-four inches. In the present case the child was delivered (still-born) by the forceps.—*American Med. Chir. Rev.* May, p. 524.

Iodine and Belladonna in Inflamed Mamme.—Dr. Weatherly has used the following ointment with excellent effect in several cases of severe inflammation of the breast.—*R. Iodin. gr. xv., ext. bellad. gr. xx., cerat. jii. M.*—*Ibid.* May, p. 526.

Parturient Effects of Sulphate of Morphia.—Dr. Byrd says, I do not regard morphia as possessing superior properties to ergot, but I believe that it is as generally certain in its effects; and I have several times administered it with success in arousing the dormant contractions of the uterus, when the secale had failed.—*Ibid.* p. 529.

FOREIGN CORRESPONDENCE

FRANCE.

PARIS, June 20, 1859.

THE experiments made of late years by Legroux, Monneret, Andral, Trousseau, and other celebrities connected with the French school, have proved, beyond a doubt, the beneficial influence of quinine in large doses in the treatment of acute rheumatism, and other diseases of a similar type. Recently this same medicine has been vaunted in combating certain forms of peritoneal inflammation occurring in connexion with the puerperal state, and more especially by M. Beau, who, during his official connexion with the Cochin Hospital, employed it in an immense number of cases where that formidable disease prevailed in an epidemic form. So marked was the success which attended his experiments, that he ultimately arrived at the conclusion, that quinine in large and continued doses, if not a specific in that disease, is at least the most valuable, and at the same time the most powerful curative agent we possess in its management and treatment. Entertaining such views in reference to the value of quinine in puerperal peritonitis, it was exceedingly natural that he should try the same remedy in a similar affection occurring apart from the puerperal state; and hence we find, that in the idiopathic form of peritonitis he has recourse to the same mode of treatment, and urges on his pupils its decided superiority over every other with which he is acquainted. In a disease of this kind, which, in spite of the most active and energetic measures we may adopt, most generally pursues its fatal course with amazing rapidity, we are always disposed to accord a favourable reception to any theory, however novel and unsupported by facts it may be, provided only we be told that its practical application has been followed by merely partial success; and we are always most agreeably surprised when, with preconceived notions unfavourable to the theory, we find ourselves confronted with a single fact which, though it may not completely establish the new doctrine, at least enlists our sympathies in its favour. Such was the surprise which we experienced in reference to the quinine treatment recommended by M. Beau, when we witnessed, for the first time a fortnight ago, a genuine case of idiopathic peritonitis treated and cured by this medicine, to the entire exclusion of every other therapeutical measure. To those who have been taught in early life that inflammation of the peritoneal membrane demands, in the majority of instances, the abstraction of blood—if not generally, at least locally—until a powerful impression be made on the system, and that this heroic plan of treatment must be followed by the assiduous exhibition of calomel until the patient be brought under the influence of this powerful and dangerous mineral, the solemn declaration of a man of high authority and great experience, to the effect that such treatment is not only useless but positively pernicious, cannot be viewed with any other feeling than that of amazement; and yet, reluctant though they be to abandon a system which has been inculcated in their youth, and which they have been accustomed to regard as strictly orthodox, they must resign themselves to seeing it demolished by another diametrically its opposite.

As a sequel to the foregoing remarks, we cannot do better than place before your readers the following case, the details of which we extract from our Medical notes taken at the bedside of the patient. A girl, 24 years of age, was admitted into the service of M. Beau, at the Hôpital la Charité, and

on examination the following symptoms were recognised. Over the lower part of the abdomen there were great pain and tenderness, which were increased on the slightest pressure; the pulse was small, hard, and quick, averaging about 120 beats in the minute; the skin was hot, dry, and harsh; tongue furred; constant nausea, with occasional vomiting; constipation; the features were pinched, and the countenance indicated much anxiety; respiration hurried; complexion muddy, and the conjunctiva slightly yellow. The patient lay on her back, with the legs flexed on the thighs. Her previous history showed that for some weeks prior to the invasion of the disease she had been in an indifferent state of health, which she attributed to an unusual amount of bodily fatigue to which she had been subjected. In the presence of these symptoms, M. Beau at once pronounced the case to be one of acute peritonitis. Treatment: an emetic, composed of ipecac. and tart. antimon. was ordered, to be followed up by a purgative enema. The feeling of nausea having thus been removed, and the stomach prepared for the administration of the sulphate of quinine, this medicine was prescribed as follows:—two grammes (equal to thirty grains) were ordered to be divided into three doses, one of which was to be given every eighth hour, and a blister was applied to the lower part of the abdomen, over the spot where the pain and tenderness were greatest. After four or five doses of the quinine, its physiological effects, such as deafness, ringing in the ears, etc. began to manifest themselves, and consentaneous with these there was a manifest diminution of the original symptoms. The pulse from 120 was reduced to 110; the pain and tenderness of the abdomen were considerably subdued; the febrile symptoms, generally, were greatly modified, and the countenance became more placid. The quinine was ordered to be continued, together with the use of refreshing drinks, and on the fourth day of the treatment the pulse fell to 100, accompanied by corresponding improvement in all other respects.

In a week or ten days from the commencement of the treatment, the full effects of the quinine having been produced, that is to say, the original disease having been, as it were, overcome, the medicine was gradually diminished, and ultimately discontinued. The pulse has fallen regularly, and the patient is now convalescent. Now, in a case like the above, implying the undoubted existence of inflammatory action of a most important membrane, the indication, according to the notions generally entertained, would be abstraction of blood, if not from the arm, at least by the application of leeches over the seat of the disease; and we venture to say, that in a similar case such would be the practice adopted by a large proportion of Medical men. But according to the theory of M. Beau, instead of curing the disease, the abstraction of a single drop of blood would only increase the evil, and ultimately lead to a fatal result. In peritonitis, and in the phlegmasiæ generally, the blood, according to Beau, is poor in red globules, and consequently rich in fibrine; in other words, the increase of the latter is in a direct ratio to the diminution of the former. It is not difficult, therefore, to understand his determined opposition to depletion, and other measures calculated to lower the vitality of the blood. He regards the excess of fibrine as the real pathological condition on which this disease depends; that is to say, he regards the fibrine as the phlogistic principle, and whatever tends to augment the fibrinous portion of the blood must of necessity increase the fever and feed the disease. Consonant with these views he considers anemia, which is always characterised by diminution of the red globules of the blood, as one of the principal predisposing causes of the phlegmasiæ; and when this condition of body exists, exposure to cold and wet, to sudden change of temperature, or to any of the other exciting causes of inflammation, may be followed by an attack of acute peritonitis. Quinine being the sheet-anchor of M. Beau, as we have shown, in the treatment of this disease, it will not be out of place here to indicate some of the leading rules which he lays down in reference to the manner in which it should be employed, and on the rigid observance of which the success will depend. It is necessary that a decided effect be produced on the system at once, and hence the earlier the quinine is exhibited after the malady has declared itself the better. But in every case he deems it advisable to premise the first dose of quinine with an emetic; to be followed up by a purgative enema. As soon as the stomach is prepared to retain the quinine, he gives the latter to the extent of eight grains every eighth hour, and this quantity of the salt must be continued for several days in

succession. It is right, however, to observe that the dose must be proportioned to the sensibility of the patient; that is to say, it must be increased should the intoxication produced by it prove too feeble, and diminished in the event of its being too strong. M. Beau has never, in the course of his experience, had occasion to prescribe a larger dose than four grammes (60 grains) of the salt in the twenty-four hours. Even when the inflammation of the peritoneum is limited to one spot, and when the malady has been to a certain extent overcome, it becomes imperative towards the second or third day to increase the dose of the salt to a small extent, as the system becoming accustomed to it, the quinine in its original dose would not suffice to maintain the mastery over the disease. For the same reason the medicine must not be diminished too rapidly, nor discontinued too early. Beau states that he has seen cases in which, up to the eighteenth day of the disease, he could not suspend the medicine without such suspension being followed by a recurrence of the febrile symptoms. Should the stomach from excessive irritability reject the quinine (by no means an uncommon occurrence), it should again be administered in some other form, so that if one form does not suit another may. When, notwithstanding the form in which it is administered, the stomach obstinately refuses it, the quinine may be given in the form of enema, as experience has proved that its absorption readily takes place when given in this manner.

GENERAL CORRESPONDENCE.

EVIDENCE OF RAPE ON INFANTS.

(MR. WILDE'S ANSWER TO MR. BROWN.)

[To the Editor of the Medical Times and Gazette.]

SIR,—“Save me from my friends” is an old and trite adage, and I think very apposite to Mr. Brown's defence of his brethren at Heywood, for whom he has fired his “first and last shot” in your number for the 18th June. 1. Mr. Brown says, my “remarks are calculated to create a wrong impression of the General Practitioners of this town” (Heywood). 2. That the learned judge who tried the case “refused to interfere, preferring the evidence of the two highly-respected Practitioners who had been eye-witnesses of her case, etc.” 3. That “the characters of *noma pudendi*, etc. are well known to any reading first year's student.” 4. That “we have learned nothing new” from the discussion. 5. That his belief is that “without any violence having been used, the child became inoculated with the poison of syphilis from the genitals of Amos Greenwood,” and died thereof. 6. And finally, that he, Mr. Brown, has “neither time nor inclination to continue this subject.” With respect to Mr. Brown's sneer at my endeavours to “enlighten the Practitioners of Heywood,” who “have resolved to be of the same opinion still,” I beg to assure these gentlemen that by no stretch of my imagination did I even aspire to any such thing. Allow me, however, to reply to the foregoing statements and accusations numerically.

1 and 2. Except by reference to the map of Lancashire, I have no knowledge of Heywood-in-Heap, and I know nothing of its general Practitioners, except what may be learned from Mr. Churchill's Medical Directory for this year, where I find the names of Messrs J. Foster, J. Leach, and J. W. Pickford, and J. Taylor; but not the names of either Brown or Jameson. What the Medico-legal qualifications of three of the foregoing Practitioners of Heywood may be I possess no means of determining. As regards Mr. Pickford alone, my opinions are on record. I must, however, remind my readers that he did not see Mary Johnston (whom he swore in Liverpool died of violence and venereal or both) until eight days after the alleged assault, when the parts were in a state of mortification and slough, and when his mind had been biased by the previous statement of Mr. Jameson, that her perineum had been lacerated, and resembled the cut made in a pig's throat by a butcher—I suppose with a very blunt knife. I am not aware who the second of the “two” highly-respected Practitioners mentioned by Mr. Brown really is; as in the present state of the law he cannot mean Mr. Jameson.

3. With respect to the character of *noma pudendi* being so

"well known," I beg to append Mr. Pickford's answer to my query on this subject:—"I must confess that I was not aware of the fatal cases to which you allude in your letter when I was examined at the trial; nor even yet have I seen any description of them; so that I cannot say whether Mary Johnson's appearance in any way resembled them or not." These fatal cases are those recorded by Kinder Wood.

4. If Mr. Brown has not learned anything new, I have only to express, not my surprise, but my regret thereat, and to sympathise with you, Sir, on the expenditure of so large a space in your valuable and wide-spread journal to, so far as that gentleman is concerned, no purpose.

5. Mr. Brown believes there was no violence used. I presume he means physical violence. Here I am glad to enlist another evidence against the finding of the jury—the sworn evidence of Mr. Jameson—who I take to be the second Heywood Practitioner whose cause is defended by Mr. Brown, and against the "mature consideration, great sagacity, and good common sense" of that "learned functionary" the Judge who tried the case, and who wrote to me as follows:—"It was proved to the satisfaction of the jury that the prisoner, who slept with the deceased, a female child of nine years of age, had forcible connexion with her, and that her private parts had been dreadfully lacerated, and the perineum ruptured."

As respects the syphilitic inoculation, when Mr. Brown can, from any well-established record of even a single case, in any work, in any language, produce a parallel with the symptoms under which Mary Johnston died, then, but not till then, the Profession can entertain the question.

In conclusion, I have to assure the Practitioners of Heywood that not knowing anything about them, I could not have intended them any slight. With any druggist's assistant or any unlicensed Practitioner at the time of the trial I have now nothing more to do. I believe Mr. Pickford erred in attributing the symptoms exhibited by the deceased to violence and syphilis—an error into which, at least as great a man, Mr. Ward, of Manchester, fell nearly seventy years ago; but which he had the magnanimity to redeem by acknowledgment before a public Court.

I am, &c. W. R. WILDE.

June 25, 1859.

LOCAL ANÆSTHESIA.

LETTER FROM DR. JAMES ARNOTT.

[To the Editor of the Medical Times and Gazette.]

SIR,—In an ingenious paper on anæsthesia, by Dr. Richardson, in the last number of your journal, he mentions what he considers the defects of the mode of producing it by congelation, and compares this with other means of producing insensibility in operations.

Local anæsthesia is admitted to have a great advantage over that produced by chloroform in its perfect safety. When congelation is employed, the prevention of inflammation by it is another advantage of perhaps equal importance.

It is stated as a defect of congelation, that the tissues are hardened by it. If the Surgeon wishes to dissect a part without embarrassment from hæmorrhage (and the possibility of doing so under congelation has been reckoned one of its principal advantages by certain French and American surgeons) he must cut while it is frozen, and must give his knife a little more pressure than usual; but if he has no such wish, he can wait till the tissues have thawed, as the part does not regain its sensibility for several minutes afterwards. The duration of the insensibility is generally proportionate to the duration of the previous congelation.

The objection to congelation in the deeper operations, on account of the insensibility produced being only superficial, may, I think, be greatly removed by combining pressure with it. This not only allows the cold to penetrate deeper by arresting the circulation, but equal and strong pressure (such as is produced by a fluid) probably itself possesses some auxiliary anæsthetic effect. I have no doubt that the arm or leg, particularly when attenuated by disease, might thus be rendered completely insensible in amputation.

I am, &c. JAMES ARNOTT.

June 27, 1859.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS.—At the Comitia Majora, held on Saturday, the 25th ult., the following gentlemen were admitted Licentiates of the College:—

DYSTER, FREDERICK DANIEL, Tenby.

HARVEY, Dr. EDWARD, Robinson, Charges-street.

INGRAM, Dr. CHARLES PENFOLD, Guildford-street.

Also, at the same Comitia, the following were admitted licentiates under the recently enacted by-laws:—

ELLIOT, Dr. ROBERT, Carlisle.

WALL, Dr. CAVENDISH LISTER, Kensington.

The election of new Fellows, which was to have taken place, was adjourned to Saturday, the 22nd of October next.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners, on the 24th ult., viz.:—

BARTON, HENRY THOMAS, Newcastle-on-Tyne.

BYLES, JAMES COTTON, Victoria-park-road, Hackney.

DAVIES, EDWARD, Llansilin, Denbighshire.

DEAN, THOMAS, Slaithwaite, Yorkshire.

GOODE, HENRY, Derby.

HADLOW, HENRY, George-street, Minorities.

HARRIS, ROBY, Australia.

RICKEY, JOSEPH, Clones, county Monaghan.

SCARD, THOMAS, Army.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, June 23, 1859:—

BROWNE, CHARLES WILLIAM, West Indies.

HUDSON, ARTHUR CORT, Shelford, Lancashire.

JONES, JOHN THOMAS, Llanynys, Denbighshire.

KENT, EDMUND JACKSON, Hampton, Middlesex.

WARDEN, THOMAS MESSENGER, Stourport.

The following gentlemen also, on the same day, passed their first examination:—

BROMLEY, JOHN BOURNE, Lye, near Stourbridge, Worcestershire.

BUSH, DANVERS WARD, Finsbury-circus.

DAWSON, FREDERICK, Union-place, Islington.

FERNIE, EDWARD, Wellingborough, Northamptonshire.

MILLER, THOMAS, Bayton, Suffolk.

WALKER, RICHARD PETTIFOR, Birchfields, Birmingham.

APPOINTMENTS.

HORACE DOBELL.—DR. HORACE DOBELL has been elected Physician to the Royal Infirmary for Diseases of the Chest.

REED.—MR. GEORGE REED, formerly House Surgeon to St. Bartholomew's Hospital, has been elected Resident Medical Officer to the London Fever Hospital, in the room of Dr. Scurrah, resigned.

DEATHS.

EDWARDES.—May 29, of Diphtheria, at his residence, Tottenham-road, Wolverhampton, Mr. George Edwardes, F.R.C.S., aged 51.

GRIFFITH.—On June 23, at Torquay, Samuel Griffith, M.D., of St. Thomas'-street, Southwark.

MUTTER.—Dr. Thomas Dent Mutter, Professor of Surgery during many years at the Jefferson Medical College, Philadelphia, and well known in this country by his bold, plastic operations, died at the end of March, in the 49th year of his age.

VALLON.—On the 6th April, at Rhodes, Dr. Vallon, Professor of Clinical Medicine at the Imperial School of Constantinople.

THE Royal Free Hospital has netted about £2000 by its annual dinner this year.

ANOTHER victim to the Bradford Poisoning died last week after a lingering illness.

P. KERNAN, ESQ., has bequeathed very nearly £8000 to be divided equally among different charitable institutions. The London Fever Hospital comes in for about £1000.

DR. MILLER, on June 23rd, reported the condition of the Thames improved. "Except with a rising tide, during the middle of the day, there has not been much cause of complaint from offensive smell."

E. C. TUSTIN, Esq., has by will left £100 to each of the following institutions:—Charing-Cross Hospital, Westminster Hospital, St. Mary's Hospital, Consumption Hospital, Brompton, and the Cancer Hospital.

THE HARVEIAN ORATION was delivered at the College of Physicians on Wednesday, by Dr. Aldis. It was well delivered, and cordially received by a distinguished assembly; but we are compelled to defer a report until next week.

PARIS FACULTY OF MEDICINE.—The Paris Faculty has just made its selection from the candidates for the two vacant chairs, bestowing that of Physiology upon M. Longet, and that of Pharmacy upon M. Régnault.

THE College of Physicians of London have presented their late Registrar, Dr. Francis Hawkins, with a purse of one hundred guineas, as a mark of the great value at which they set the services preformed by him during his many years of Registrarship at the College.

IN THE TREATMENT OF DYSENTERY, M. Leclerc, of Tours, finds that the application of plasters of belladonna or of stramonium, applied above the pubes, and renewed every day, very quickly relieve the tenesmus, and shorten the progress of the disease. He combats the diarrhoea by nitrate of silver lavements, and pill of opium and nitrate of silver and rhatany extract.

DR. CHRISTISON, in the last April number of the *Edinburgh Monthly Journal*, gives an interesting account of a new poison from the interior of China. Wonderful tales are told in China of its powers. Dr. Christison brings them down to their true value. He believes it to be a species of aconitum. The extract sent to him is made (he says) with great care and skill; and the most minute portion of it acts with extraordinary intensity on the tongue and lips, producing numbness and tingling. The poison is obtained from a root called tsau wü.

HER MAJESTY'S LEVEE.—The following Medical men were presented at the levée last Saturday:—Assistant-Surgeon J. W. R. Amesbury, on his return to England, by the Secretary of State for India; Surgeon Cowen, Ceylon Rifles, by the Adjutant-General; Assistant-Surgeon A. J. Dale, by the Secretary of State for India; Surgeon-Major R. C. Elliott, C.B., on return from India, by Col. Bingham; Dr. Leckie, on his return from India, by the Secretary of State for India; Dr. Robert M'Cormack, Deputy Inspector-General of Hospitals and Fleets, on promotion, by the Duke of Somerset; Surgeon-Major O'Flaherty, on return from service in China and India, by the Adjutant-General; Mr. T. P. Teale, on being appointed a member of the Medical Council by the Queen, by the Right Hon. T. Sotherton Estcourt.

AN IMPORTANT CASE.—M. Langenbeck, of Berlin, relates a very interesting case of recovery from the asphyxia of chloroform through tracheotomy. All ordinary attempts at insufflation were unavailing. The pulse had stopped; the face had the pale aspect of death; the lower jaw fell; the eyes were widely opened; and all present were convinced that the man was dead. "It was then," he says, "that I opened the trachea. Not a drop of blood flowed during the operation; the circulation having entirely ceased, artificial respiration was then begun. After six or eight movements of inspiration and expiration, the pulse returned, but feeble, and irregular at first, and then more regular. Then came a spontaneous inspiration; and now the wound began to bleed. Frictions and cold affusions were continued, for life seemed still trembling in the balance. The expression of the face was still unchanged; the eyes still wide open and staring; the left pupil more dilated than the right; the features were immovable; pinching the skin of thorax produced only reflex movement of the upper extremities. Their efforts were con-

tinued for an hour and a-half, when the patient had a coughing fit, and brought up a quantity of bloody mucus. He was then carried to bed. There he was seized with clonic spasms, etc. He was still insensible, but his respiration was free. He at length became excited, and required the strait waistcoat. The insensibility and excitement continued during the night, but next morning the effects of the chloroform had disappeared."—*Arch. Génér.*, June, 1859.

TO CORRESPONDENTS.

Mr. Thomas should apply to Mr. Probert, the Treasurer of the College.

Papers are in type by Dr. Stone, Mr. Haynes Walton, Mr. Lawrence, Mr. Redfern Davies, etc.

Papers on Diphtheria by Dr. Ballard and Dr. Bristowe, will appear in early numbers of this volume.

A Doctor.—The Royal College of Physicians of London have decided upon giving a soirée at the College this season.

Mr. Marshall.—The only information we have about the Bréant prizes was given in our number of April 2, this year.

Mr. Symmons.—Any of the principal druggists would procure it for our correspondent.

M.B. if registered as in practice before 1815, can recover both for attendance and medicines.

R.N. should apply to Sir John Liddell, Somerset-house. The request would probably be granted.

J. S.—Any Medical man wishing to serve with either army in Italy should apply to the Austrian, French, or Sardinian Embassy.

Fin.—An "Egyptian Institute" has been recently founded at Alexandria. Dr. Schnepf, the French Sanitary physician there, took the lead in its formation.

M.R.C.S.—The uniform of Naval Medical officers has been much improved since the late Warrant. There is now no cause for complaint on this head.

Esse quam videri.—He is fully entitled to practise as a Union Medical officer, and to sign certificates of death, etc. If he charge for medicine supplied to patients, he subjects himself to the Apothecaries' Company; but the Company would not proceed against a qualified Surgeon.

Mr. G.—The decision as to the payment of Medical officers of large establishments depends upon the question whether these establishments are, or are not, public institutions. Borough prisons, and borough or county lunatic asylums, being supported by local or county rates, are not public institutions supported by the consolidated fund or by endowment. Medical officers of any local institution—in other words, of any institution supported by local rates—can claim a fee from the Coroner for giving evidence as to the cause of death of any inmate of the institution.

L. M. N. R.—1. Dr. De Roos's name does not appear in the Medical Directory. 2. The College of Surgeons have the power to erase the name of any member from the list who is proved to have done anything deserving of such a punishment. 3. The Western Institution is quite unknown, except by the De Roos' advertisements. 4. The Medical Registration Associations may do much towards putting down such fellows as Kahn, and De Roos.

A Medical Ticket of Leave, for J. M.—Can a Practitioner convicted of felony be deprived of his right to practise—Certainly—1st. By the College to which he belongs depriving him of his diploma or licence, in which case the General Council "may, if they see fit, direct the Registrar to erase forthwith from the Register his qualification derived from such College or Body." (Med. Act, sec. XXVIII.) 2nd. By the General Council who are empowered "if they see fit" to erase from the Register the name of any one convicted in England or Ireland of a felony or misdemeanor, or in Scotland of any crime or offence, or who shall, after due inquiry, be judged by the General Council to have been guilty of infamous conduct in any professional respect (Sec. XXIX.)—Yours, &c. NO LAWYER.

A Sufferer.—The physic used by "Dr. Watters and Co." at the British and Foreign Infirmary for the Cure of the Diseases of the Ear and Eye. "There were five compositions—cardrops, embrocation, injection, fumigation, and tincture. This bottle contains the embrocation, and this the injection. This is urine; they are all the same differently coloured. The fumigation has no oil in it, the others have oil; this one is hair oil—what they call cabbage oil—and urine. This red mixture is a solution of cochineal and urine. The urine extracts the colour from the cochineal. This one is drops for the ear. Two or three of these went together, and they were charged from a shilling to £2, £3, and £4; it depended on the patients. We had a great many patients, I should imagine 20 or 30 a day. I kept the books and made entries. I have not the books with me. The profit was at least £2,000 for each of the two brothers Bennett. These filthy vagabonds appear to be in the way of reaping a few of the rightful fruits of their rascality. What a fine field to sport over is that of human credulity!

NORWICH UNION LIFE OFFICE AND MEDICAL FEES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have, as one of the directors of the Norwich Union Life Office, much pleasure in announcing the following resolution with reference to the payment of Medical fees:—

"At a meeting of the Board of Directors of the Norwich Union Life Office, held on the 23rd ult. it was unanimously resolved that all Medical opinions required be from this time paid by the office."

Norwich, June 24.

I am, &c. W. H. RANKING, M.D.

THE MEDICAL SOCIETY OF LONDON.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—My attention has been directed to a statement made at page 581 in your journal of June 4th, announcing that forty Fellows of the Medical Society of London have signed a memorial to the President of the Society regarding the illegality of the elections of some of the Members of the Council, etc. etc. I beg to assure yourself and the Fellows of the Medical Society, that I have not received any such memorial.

June 28th.

I am, &c. JOHN HILTON,
PRESIDENT OF THE LONDON MEDICAL SOCIETY.

REGISTRATION OF PERSONS IN PRACTICE BEFORE 1815.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—A general feeling is gaining ground in this neighbourhood, that the New Medical Act is really worse than useless, and as Honorary Secretary of the Thorne and Goole Medical Registration Association, I have been requested to send you a short account of a recent occurrence, by which a person generally known as unqualified has now come forward with the sanction of the law. I will briefly relate the facts without mentioning the names. A.B. applies to this association for admission as a member, and for registration. After most careful consideration and correspondence with a Medical gentleman long in practice, in a town where A.B. claimed to have been in practice before 1815, as well as with a member of the Council of a Medical Registration Association of the district, he was refused admission on the ground that he had no qualification whatever, in fact, that he had been merely a druggist. Information was forwarded by me to the Registrar of what had been done. A short time since it was stated that any one could get registered, for A.B. had actually succeeded in getting registered. I wrote to Dr. Hawkins asking the question, and he replied that it was so, that A.B. had sent in a claim, and had made an affirmation before a magistrate, which he had refused, but afterwards an attestation had been made in the form of a letter, signed by a gentleman on the register, and that he could not then refuse registration. I then applied for the name of the gentleman that we might prosecute the inquiry further. Dr. Hawkins, in his reply, stated that he had laid my letter before the Council, and they did not consider themselves justified in giving up the name of the gentleman, as it was considered a privileged communication. Now we considered this very unjust; in the first place, we contend that A.B. ought not to have been registered at any rate without communicating to this association, after we had taken the trouble of carrying on a correspondence on the subject, and had sent the result to the Registrar; secondly, that as no one in the neighbourhood knows anything about it, that it was the duty of the Registrar to have given us the name of the party, in order that further inquiries might have been made if necessary. I should have stated that Dr. Hawkins added, that the Council would cause A.B.'s name to be erased from the register if we could prove he was not qualified; but surely, after we had made a good case, proving that he was not qualified, something more should have been required than a mere affirmation attested by somebody, who, they will not inform us, before the party in question was registered. It is most unjust to shift the onus of proof from the party claiming to be registered, to this association. If registration is to be conducted in this way, Registration Associations are utterly useless, and the Medical Act a positive injury, for which qualified Practitioners have to pay.

I am, &c. R. GILLARD, M.R.C.S. Eng. and L.S.A.

Hon. Sec. of the Thorne and Goole Medical Registration Association, [We have repeatedly expressed our opinion that extreme care should be taken by the Registrar in claims by persons said to have been in practice before 1815, before admitting them upon the Register.—Ed.]

AIR PLUGS IN OBSTETRIC PRACTICE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I am very unwilling to enter into any further controversy with your correspondent, Mr. J. Jardine Murray, anent a matter which is of so little professional importance, as the determining whether a particular case did or did not belong to me. But seeing that Mr. Murray has published a statement from the Medical Student who had the charge of the patient from the Dispensary, I think it proper to mention that I visited the poor woman at the special request of Mr. Picard; that I told him what I thought should be then done with the case; that I advised him to watch her very carefully; and particularly requested him to acquaint me with the progress of the case, and which he afterwards took care, on repeated occasions, to do. From what thus transpired, I had every reason to believe that Mr. Picard was attending to the case under my directions, and therefore felt justified in asserting that its treatment and responsibility lay principally with me, and that "my late Hospital Clerk," Mr. Murray, was merely called to visit the patient during my absence; in proof of which, notwithstanding the statement of Mr. Picard, I can offer the very best evidence, viz. that of Mr. Murray himself, who, on seeing the case with his friend Mr. Picard, lost no time in coming to my house, with the view of consulting with me as to what should be done, and of securing one of my dilators, for the purpose of applying it as he afterwards did. Finding me from home, however, he went over to the Hospital and got an air-dilator, and returned to Mr. Picard, and used it, I am glad to say, successfully.

Mr. Murray met me during my visit to the Infirmary on the following day, and told me what I have now stated, and seemed pleased at being enabled to communicate to me the happy manner in which the case had been terminated; but it turns out that he said nothing to Mr. Picard, on returning to the case, as to his ever having come in search of me or my dilator—a circumstance which, if made known to Mr. Picard previously to his supplying the statement published by Mr. Murray, might well have modified his opinions regarding the whole matter.

As my paper on the Obstetric Appliances of the Air-dilator is about to appear in the *Edinburgh Journal of Medical Science*, I shall here abstain

from stating my special views regarding it, but shall only add, that on no occasion have I spoken of, or in any way claimed, the air-pessary as an invention of mine; but having found it to serve a much more useful purpose than the one which it was originally and specially intended for, I hope that Mr. Murray will kindly forgive me for presuming to refer to it, as I believe I am entitled to do.

I regret being compelled by the haughty tenor of that gentleman's observations, to state that it is only within the last few weeks that he left the Edinburgh Hospital and Medical School; and, if what he asserts be really true, that he "knows next to nothing about (what he is pleased to call my) doings," I can only say that it is no fault nor business of mine.

I append a note which I received on the subject, from the "friend" whose prescription received a foot-note kick from Mr. Murray; but whose knowledge and opinion of the circumstance referred to may, nevertheless, be considered amply trustworthy.

I am, &c. ALEXANDER KEILLER.

21, Queen-street, Edinburgh, June 28.

Copy of a note from Dr. Little to Dr. Keiller.

My dear Dr. Keiller,—I have just read in the *Medical Times and Gazette* a case of "Placenta prævia," reported by Mr. Murray, of Brighton, and which case I once saw in your company.

Mr. Murray takes credit to himself for applying the "India-rubber dilator," as a plug, and would make the Profession believe that he was the first to suggest such a use of the instrument, and seems to ignore any share you have had in the matter, when he observes that he "believes that to Dr. Keiller of Edinburgh, we are indebted for extending their application to the dilatation of the passages in primiparae, and in the induction of premature labour."

I am surprised that any one, more especially one of your late Clerks, could have the presumption to attempt to appropriate this application of yours—when it was well known to those attending the "Midwifery department" of the University and Infirmary, during the winter and present session, that you were the first to use and recommend the "Air-dilator" or "Vulcanised Pessary," as an obstetric instrument. I consider myself fortunate in having witnessed your first application of it, along with Dr. Graham Weir in the case of Mrs. F. who had the operation of craniotomy performed in her first two pregnancies (in one instance by Dr. Simpson, and in the other by yourself) on account of an extremely contracted pelvis.

In this, her third pregnancy, you thought of saving the child, and not endangering the life of the mother, by inducing premature labour. This was done in the month of March last, and there is no doubt that the dilator, which you then used for the first time, enabled you to save the child after the waters had escaped. Since then, you have, to my knowledge, used this instrument for many purposes connected with the obstetric art, and mentioned in your lectures the various cases to which you consider it applicable; and I have no doubt that by thus shortening the term of labour with safety both to mother and child, you have done much that will tend to save the obstetricians valuable time.

Trusting that you will not delay further in publishing your cases bearing on this subject,

I am, &c.

R. LITTLE, F.R.C.P.E.

17, Fettes-row, Edinburgh, June 14, 1859.

COMMUNICATIONS have been received from:—

PROFESSOR SIMPSON; DR. KEILLER; DR. ALDIS; DR. DRUITT; DR. MCWILLIAM; DR. WOODSON, Tennessee; DR. SCOTT ALISON; DR. MURCHISON; DR. O'MEAGHER, New York; DR. THUDICHUM; MR. CHARLES HAWKINS; MR. APPOINTMENTS FOR THE WEEK.

July 2. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m. King's, 2 p.m.; Charing-Cross, 1 p.m.

4. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.

EPIDEMIOLOGICAL SOCIETY, 8 p.m.
ENTOMOLOGICAL SOCIETY, 8 p.m.

5. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

6. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopaedic Hospital, 2 p.m.; Middlesex, 12½ p.m.

OBSTETRICAL SOCIETY OF LONDON, 8 p.m. Papers by Dr. Clay, of Manchester; Dr. Rigby; Dr. West, of Alford; Mr. Mackinder, of Gainsborough; Dr. Priestley, and Mr. Trouncer.

7. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2½ p.m.

8. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

EXPECTED OPERATIONS.

King's College Hospital.—The following operations will be performed this day (Saturday):—

By Mr. Fergusson—Excision of Knee-Joint; Fistula in Ano; Hæmiplegia. By Mr. Bowman—For Varicose Veins.

JULY 2, 1859.

MEDICAL TIMES AND GAZETTE ADVERTISER.

Medical Times and Gazette.

Vol. I. for 1859 was concluded on SATURDAY, JUNE 25.

IT MAY BE HAD, BOUND IN CLOTH, PRICE 17s.

THIS VOLUME CONTAINS SIXTEEN CLINICAL LECTURES ON THE DISEASES OF WOMEN, BY PROFESSOR SIMPSON.

LECTURE 1.—On Vesico-Vaginal Fistula.

2.—On the Treatment of Vesico-Vaginal Fistula (*with eighteen engravings*).

3.—On the Pathology, Symptoms, and Diagnosis of Cancer of the Uterus (*with four engravings*).

4.—On the Palliative Treatment of Cancer of the Uterus (*with three engravings*).

5.—On the Surgical Treatment of Cancer of the Uterus (*with seven engravings*).

6.—On the Treatment of Carcinoma of the Uterus and Mamma by Caustics (*with three engravings*).

7.—On Dysmenorrhœa (*with four engravings*).

8.—On the Treatment of Dysmenorrhœa (*with seven engravings*).

9.—On Closures, Contractions, and Fissures of the Vagina and their Treatment.

LECTURE 10.—On Urethral Caruncles—Neuromata of the Vulva—Hyperæsthesia and Neuralgia of the Vulva (*with three engravings*).

11.—On Abscess of the Labia Pudendi, and the various forms of Vulvitis.

12.—On the Causes of Death after Surgical Operations and Injuries.

13.—The Causes and Symptoms of Surgical Fever (*with three engravings*).

14.—The Preventive and Curative Treatment of Surgical Fever.

15.—The Symptoms, Diagnosis, and Pathology of Phlegmasia Dolens.

16.—The Treatment of Phlegmasia Dolens (*with an engraving*).

This Volume also contains THREE LECTURES by Dr. PRIESTLEY on the

DEVELOPMENT OF THE GRAVID UTERUS,

Two PAPERS by Dr. CONOLLY, with Illustrations of the

PHYSIOGNOMY OF THE INSANE,

LECTURES and ADDRESSES by Sir JOHN FORBES, Professor OWEN, Mr. GREEN, and Mr. PAGET; and Communications from the following Gentlemen:—Acton, Adams, Alison, Althaus, Anstie, Armstrong, Arnott, Atcherley, Aveling, Barclay, Barlow, Barnes, Barry, Brady, Bastick, Braithwaite, Browning, Bruce, Bryce, Buchanan, Buckland, Budd, Bullar, Bulley, Bryant, Cameron, Camplin, Carson, Channing, Chapman, Cheestham, Clark, Corbitt, Cotton, Crawcour, Crondace, Davey, Davies, Dick, Duggan, Dunn, Dymock, Edwards, Evans, Fenwick, Field, Figg, Fleming, Fletcher, Fox, Gallagher, Gamgee, Gay, Gibb, Hewson, Hillier, Hodge, Hornidge, Hoshier, Hulme, Hutchinson, Humble, Holthouse, Hunter, James, Johnson, Jones, Kealy, Keiller, Kesteven, Lawrence, Lawson, Laycock, Lee, Leared, Lowes, Lethaby, Lizars, Mackenzie, Marcet, Markham, De Mussy, Monckton, McCraith, McDermott, Maumder, Maysmor, Meadows, Milroy, Moore, Ogle, Parker, Pittard, Prichard, Pollock, Ramsbotham, Richardson, Robinson, Rolleston, Rooke, Rowth, Savery, Scott, Sedgwick, Shaw, Smith, Stallard, Startin, Taylor, Toynbee, Turner, Tuson, Wade, Waller, Walton, Wells, Wilde, Williamson, Wood, Wright, Young, &c.

The FIRST NUMBER of the SECOND VOLUME for 1859
IS PUBLISHED THIS DAY.

IN THIS VOLUME

Dr. SIMPSON'S CLINICAL LECTURES on the DISEASES of WOMEN WILL BE CONTINUED,

And each Number will contain Original Communications of the same high order as have distinguished former Volumes:—Reports of Practice in the London and Provincial Hospitals, Medical Notes and Queries, Editorial Articles on all the Medical Questions of the Day and the relations of the Profession to Collateral Science, to the Public and the State, Reviews of New Books, Selections from the most important and practical Papers in the principal Foreign Journals, Correspondence from Paris, Edinburgh, Dublin, &c., Reports of the Papers read at the Principal Medical Societies with the Discussions, Letters from Correspondents on Passing Events and Cases of Interest, with all the Medical News of the Week, Literary, Scientific, or Practical.

The First Number of the Volume is sent to every Medical Man in the United Kingdom,

and it is hoped that the present favourable opportunity for Commencing and Renewing Subscriptions will not be passed over. Every additional Subscriber increases the means of the Proprietors to add to the value of each department of the Journal, and no expense will be spared to maintain and improve the position acquired.

Price Unstamped, of any Bookseller, 7d., or £1 10s. 8d. per annum.

Price Stamped, 8d., or £1 14s. 8d. per annum.

Or, if PAID IN ADVANCE, by Post-office Order, or otherwise, £1 10s. per annum, for which sum the Journal will be regularly transmitted free by post.

SUBSCRIBERS

Are regularly supplied with the MEDICAL TIMES AND GAZETTE, FREE BY POST, to all parts of England, Scotland, Ireland, the Channel Islands, the United States of America, Canada, Nova Scotia, New Brunswick, Newfoundland, Australia, the East Indies, Ceylon, Hong Kong, Mauritius, British West Indies, Bermuda, Malta, Gibraltar, the Ionian Islands, St. Helena, the Gold Coast, Sierra Leone, Capetown, New Zealand, and in France, Turkey, Egypt, and Greece. A small additional postage is chargeable in Germany and Italy, and in the Mediterranean generally, if sent by French packet.

Orders on Bankers, Army and Navy Agents, to be addressed to Mr. JAMES LUCAS, 11, New Burlington-street. Post-office Orders should be drawn in favour of Mr. James Lucas, and made payable at the Post-office, Old Cavendish-street, London, W.

A FEW COMPLETE SETS REMAIN OF THE EIGHTEEN VOLUMES OF THE PRESENT SERIES.

The Journal is also supplied in Monthly Parts, stitched in a Wrapper, by all Booksellers.

JOHN CHURCHILL, NEW BURLINGTON-STREET, W.
AND ALL BOOKSELLERS AND NEWSMEN IN TOWN AND COUNTRY.

WALTERS' INDIA-RUBBER URINALS.

F. WALTERS having originally invented these Urinals, begs to warn the Profession of the many bad and useless imitations which are now sold, and he would advise them, before purchasing, to look that they are stamped with his name; as, unless that be the case, he cannot guarantee them.

These conveniences are made for those who require them only occasionally, during a long journey, as well as for those invalids who use them always. MR. WALTERS has much improved them by making them of *Ætherised India-Rubber*, which adds very greatly to the strength of the India-Rubber, at the same time that it prevents its sticking together; by this means he is enabled to make them less stiff and harsh than hitherto, and yet to retain all the advantages of that stiffness. There is a patent valve, which prevents the return of the fluid; and they may be worn either sitting, walking, or lying, without the slightest inconvenience, and without being perceived by any one.

WALTERS' CONVENIENCES FOR LADIES will be found particularly useful during pregnancy. They are perfectly soft and flexible, and may be worn with perfect comfort.

WALTERS' RECTUM-BAG FOR INCONTINENCE OF THE FÆCES.

This is a complaint which has hitherto had no remedy or alleviation; but F. WALTERS has now perfected an instrument which he will be happy to show and explain to the Profession, and which he can recommend as perfectly successful, having applied and tested one for more than six months.

WALTERS' WATER-BAG OF ÆTHERISED INDIA-RUBBER.

In consequence of the complaints which were made, and the number of the Vulcanised Water Cushions which were brought for repair, MR. WALTERS has for some time endeavoured to bring out a Water Cushion, which should be without smell, more durable, and more economical than the former ones. This he has now succeeded in doing, and can offer them at the following prices:—

No. 1. 14 inches by 9 inches, 12s. 6d.
No. 2. 16 inches by 10 inches, 15s.

No. 3. 19 inches by 12 inches, 17s. 6d.
No. 4. 22 inches by 14 inches, 20s.

No. 5. 25 inches by 16 inches, 22s. 6d.
No. 6. 28 inches by 18 inches, 25s.

MANUFACTURER OF ELASTIC STOCKINGS, BELTS, &c.

WALTERS' HYDROSTATIC TRUSS, HYDROPNEUMATIC ENEMA SYRINGE, AND SURGICAL INSTRUMENTS OF ALL KINDS.

16, MOORGATE STREET, NEAR THE BANK, LONDON. E.C.

J. & E. BRADSHAW,

LATE

SHOOLBRED AND BRADSHAW,

34, JERMYN-STREET, LONDON,

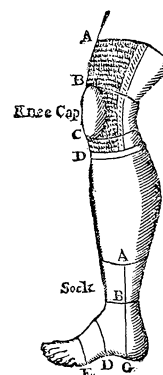

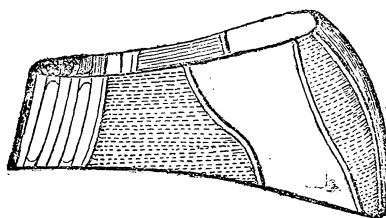

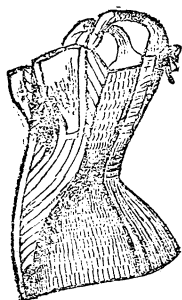

Patentees of the Elastic Stocking, Knee-Cap, Socks, Abdominal Belts, &c.

For Varicose Veins, Weak, Swollen, or Dropsical Affections, Accident to the Knee Joint, Increase of the Synovial Fluid, and in all Rheumatic and Gouty Affections.

J. AND E. BRADSHAW beg particularly to call the attention of the Profession to the improvements they have made in the above articles, whereby all the objections hitherto existing have been overcome.

J. and E. B. have likewise made arrangements for the Manufacture of all Surgical Bandages in India-rubber, vulcanised on a principle whereby the elasticity is preserved and not affected by Climate, the Bandages being all made from patterns taken from each particular case; a perfect fit is secured thereby, preventing the many evils arising from undue pressure being applied to any part, which must always be the case providing the Bandage is not adapted to each particular case.

Prices, which will be found as low as other makers', notwithstanding the advantages offered, together with directions for measurement, will be sent on application, per return of post.

Every description of India-Rubber Bandage Vulcanised on the Newest Principle.

Directions for Measurement sent by Post. A liberal discount to the Profession. A Female to attend on Ladies.

BROWN & POLSON'S

PATENT CORN FLOUR.

THE ACKNOWLEDGED SUPERIORITY OF THIS ARTICLE TO THE BEST ARROW ROOT, AND ALL OTHER FARINACEOUS DIETS CONSISTS IN ITS PURITY, SNOWY WHITENESS, AND DELICACY OF TASTE, ITS WHOLE-SOMENESS AND EASY DIGESTIBILITY.

In comparison with the numerous similar articles prepared from Indian Corn, the *Lancet* states:—"This is SUPERIOR to anything of the kind known."

DR. HASSALL.—"Much preferred to Arrow Root, and is SUPERIOR to anything brought under my notice for similar purposes."

Obtain it from Family Grocers or Chemists, who do not substitute inferior articles, 16 oz. packets, 8d.

When its properties are known it becomes indispensable to every family, and especially suited to the delicacy of

CHILDREN AND INVALIDS.

PREPARED TO THE FOLLOWING CORRECTED RECIPES, IT IS THE MOST LIGHT AND WHOLESOME

SUMMER DIET.

BLANC MANGE.—Take one quart of milk, and mix it with four ounces or four table-spoonfuls of the Flour; add a little salt, and flavour to taste; then boil the whole for a few minutes, allow it to cool in a mould, and serve it up with milk and jelly, or milk and sugar.

STEWED FRUIT of all kinds may be used by pouring it round the Blanc Mange set upon a pie dish.

FRUIT PIE.—Bake or stew the fruit with sugar, put it into a pie-dish, then pour over it Corn Flour boiled with milk in the proportion of four ounces of the Flour to one quart of milk; then brown it before the fire, or in the oven. This makes a covering lighter and more delicious than pie-crust.

BAKED PUDDING.—Nearly four table-spoonfuls of the Flour (or three and a half ounces), to one quart of milk; add a little salt; boil three minutes, stirring it briskly; allow it to cool, and then thoroughly mix it with two eggs, well beaten with three table-spoonfuls of sugar; flavour to taste, and bake for half-an-hour in an oven, or brown it before the fire.

STEWED FRUIT of all kinds may be used with this, either warm or cold.

CUSTARD.—One quart of milk, and mix it with three ounces of the Flour; one or two eggs well beaten; and a little butter and salt, and four table-spoonfuls of sugar. Flavour to taste, and boil three or four minutes, then pour it into a pie-dish, and brown it before the fire. This is an exquisite delicacy.

OMELET.—Beat up two eggs, and with them one table-spoonful of the Flour and a tea-cupful of milk; add a little pepper and salt, and sugar if preferred; throw the whole on a flat saucepan, previously well-heated, and covered with melted butter; keep the saucepan in motion over the fire; then turn it several times and roll it up, keeping it in motion till it is slightly browned.

SPONGE CAKE.—Half a pound of Corn Flour, quarter or half pound of butter, and two tea-spoonfuls of baking powder to be very well mixed together. Take three eggs, and beat the yolks and white separately for fifteen minutes, then add to them quarter-pound bruised white sugar; mix all together, flavour to taste, and beat for fifteen minutes; put it into a well-buttered tin, papered all round two inches deeper than the tin, and bake in a quick oven for one hour.

FOR USE AS ARROW ROOT FOR HOSPITALS AND PUBLIC INSTITUTIONS IT IS PACKED IN 28lb. BAGS AT A REDUCED PRICE.

Sold by all Wholesale Grocers, Druggists, Drysalters, etc. etc.; Parcels, 6 lb. of $\frac{1}{4}$, $\frac{1}{2}$, and lb. packets; Cases with fine lid label 12 in lbs.; Boxes with Bills and Card 36 lb. of any size or mixed packets.

No. 1, 2, 3, is J. Alderman's

Patent Graduating Elastic Couch, shown in different positions: it is fitted with two, three, or four distinct graduating sections, by which an Invalid can be graduated to any position, without being touched by the nurse, and free from all pressure, so that a patient cannot possibly become bedsores by long confinement.

No. 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100.

No. 8, 8, 8, 8 J. A.'s Patent Portable Equilibrium Carrying Chair, which enables an Invalid to be carried up and down stairs with perfect ease and safety. It is also an easy chair for the room when the handles are off, and free from oscillation.

No. 9 is J. A.'s improved Four-wheel Albert Chair, fitted for hand or pony: the body being mounted upon G and under springs behind, and elliptic springs in front, which make it a most elegant and easy carriage.

No. 10 is J. A.'s improved Four-wheel Brighton Chair, mounted upon G and under springs both back and front, and has his new wrought-iron porches or cranes, instead of the old-fashioned wood porches. This is the most elegant and easy carriage in use.

No. 11 is J. A.'s improved Three-wheel Albert Chair, with and without a head, which is as elegant and easy as can be made with three wheels.

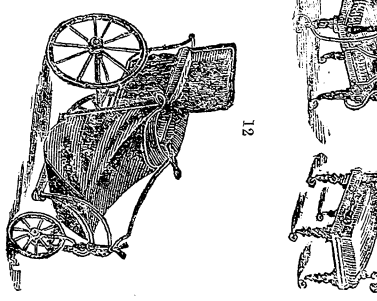

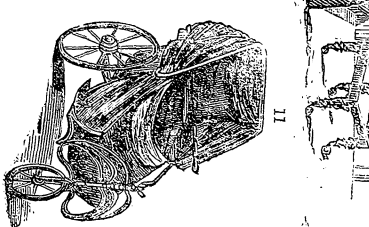

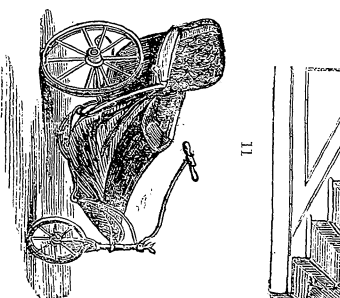

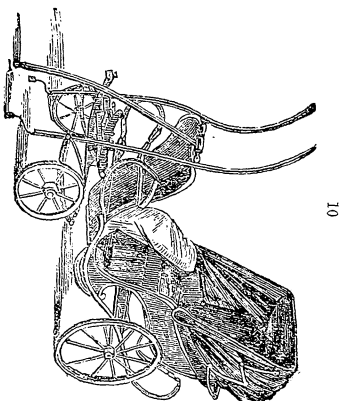

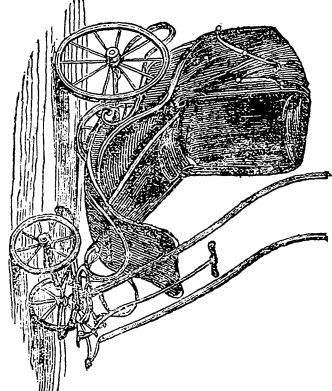

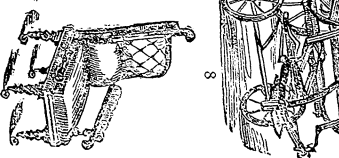

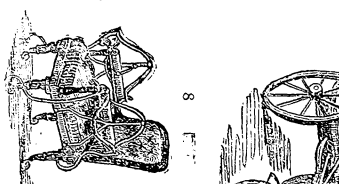

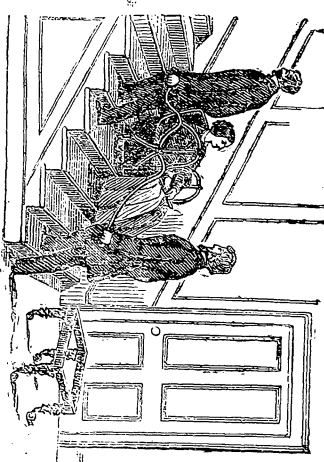

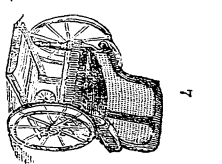

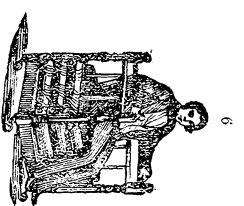

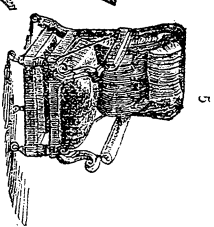

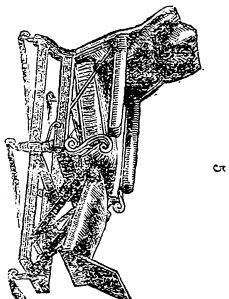

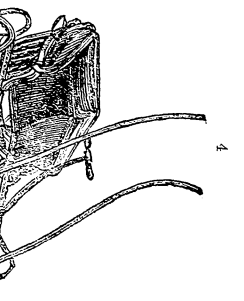

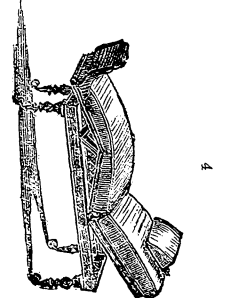

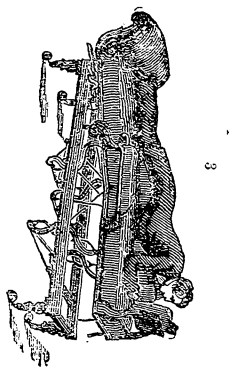

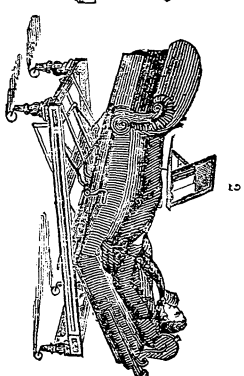

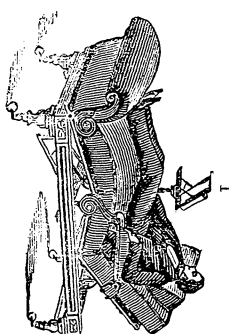

carriage without being touched, so as to go out for an airing when required.

No. 6, 6, 6, 6 J. A.'s Patent Graduating Elastic, Self-adjusting Chair, which, like the couch, is made to follow nature in every respect—the back, the arms, the seat, and leg rest being made to work all together, so that not a muscle of the patient need be disturbed. The arms are also made to put on and off, so that the patient can get on and off from either side while the leg rest is up.

No. 7 is J. A.'s improved Self-propelling Horse, which renders an Invalid perfectly independent, being able to run from room to room without any assistance.

The chair always adjusting itself, enables the two persons who carry it to walk up and down stairs in the usual way, quite erect, with their arms straight down, which avoids any strains upon their muscles.

LIQUOR SECALIS CORNUTI.

(Recognised Preparation.)

EXHIBITED AT THE "OBSTETRICAL SOCIETY OF LONDON," BY THE PRESIDENT, JUNE 1ST, 1859.
(*Vide THE LANCET, June 11th, 1859.*)

THE following is one of the numerous instances in which this Liquor has given much satisfaction. Mr. HEMSTED, of the University College Hospital, writes thus :—

" October 28th, 1858.

"I have much pleasure in stating, that after numerous trials under Dr. Murphy's direction, I have found the Liquor Secalis, as prepared by Mr. Curtis, to *far exceed* all other preparations of the kind."

Orders received by the Manufacturers,

CURTIS & CO. Pharmacutists, 15, Crawford-street, Baker-street, London;
And can be obtained through any Wholesale House in the Kingdom.

DR. DE JONGH'S

(*Knight of the Order of Leopold of Belgium*)

LIGHT-BROWN COD-LIVER OIL.

CAUTION.

Serious and repeated complaints having been made of a disreputable system pursued by many Chemists and Druggists of intrusively recommending or surreptitiously substituting a pale, yellow, or coarse brown preparation, when Dr. DE JONGH'S Oil is prescribed, the Medical Profession are respectfully and earnestly solicited to afford their assistance in counteracting and repressing a practice alike injurious to their patients and to the fair reputation of the Oil. In aid in such high and honorable estimation. In all cases where this Oil cannot be procured from a respectable Chemist, application should be made to Dr. DE JONGH'S Agents.

ANSAR, HARFORD, & CO., 77, Strand, London, W.C.

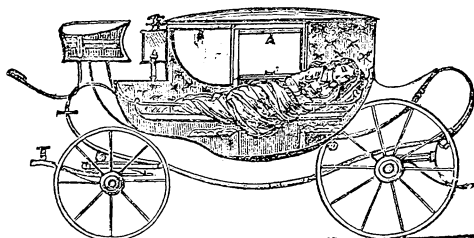

By whom any quantity will be immediately forwarded.

WATER BEDS.—EDMISTON and SON, 5, Charing-Cross, beg to call
the particular attention of the Managers of Hospitals and Dispensaries, and the Medical Profession generally, to the prices
and quality of their Hot or Cold Water Beds. The prices hitherto charged being so high as to limit the sale of such articles to the affluent, they are
induced to offer them at such prices as will enable the public

WATER BEDS ON HIRE. TERMS, 7s. 6d. PER WEEK.

LONDON: EDMISTON AND SON, 5, CHARING-CROSS, LATE 69, STRAND.

These Carriages may be engaged, on moderate terms, for any journey, on application to

H. & J. READING,

COACHBUILDERS, 14, RIDING-HOUSE-STREET, CAVENDISH-SQUARE.
Also a good assortment of New and Second-hand Broughams and other Carriages for Sale or Hire.

ADDITIONAL TESTIMONY ON THE EXTRAORDINARY EFFICACY OF DR. J. COLLIS BROWNE'S

(M.R.C.S.L., Ex-ARMY MEDICAL STAFF)

C H L O R O D Y N E.

(Entered at Stationers' Hall.)

MEDICAL PROPERTIES—Anodyne, Diaphoretic, Sedative, Astringent, Antispasmodic, Diuretic.

From W. R. DAWES, Esq., F.R.C.S.
Haddenham.

DEAR SIR,—You should have heard from me sooner respecting the effects of Dr. J. Collis Browne's Chlorodyne, but the fact is, that I have found it so universally applicable as a sedative, that there is great difficulty in making a selection of cases which most strikingly mark its beneficial action without rendering my report inconveniently prolix. I can, however, most truly say, that it is a remedy more generally efficient than any other with which I am acquainted. Its sedative and anodyne effects are not only more speedily produced, but they are also more lasting, and are not followed by exhaustion, or headache, or disturbance of the digestive functions; on the contrary, in many instances its continued use has been followed by exhilaration of spirits and improvement of appetite, especially in the various painful symptoms attending uterine irritation. In hysteria and in dysmenorrhœa, this remedy acts like a charm, as also in nervous headaches and in many cases of cough. In fevers, combined in the early stage with tartarised antimony, it is often of signal service; nor is an increase of dose usually requisite to maintain its beneficial action. In a case of phthisis, the moderate dose of ten minims, taken every night, has sufficed for many months to secure quiet rest, scarcely disturbed by cough, while the omission of it is invariably followed by a restless and coughing night. One fact strikes me as very remarkable—namely, that while the tendency of Chlorodyne to produce constipation is so slight as rarely to require an aperient, it has never failed speedily to stop diarrhœa, or to extinguish attacks of ordinary Cholera. In only two or three instances has it disagreed. The sleep which follows the composing influence of the medicine is peculiarly light and refreshing.

Caution.—Owing to the frequent complaints made by Physicians and General Practitioners of the distress and disappointment caused by the substitution of fraudulent imitations of Dr. J. Collis Browne's Chlorodyne, when prescribed by them for patients, as also vended to them as the genuine (proofs of which are in possession), it is found necessary to adopt the Government Stamp, having the name of Dr. J. Collis Browne's Chlorodyne engraved thereon.

Medical men, Hospitals, and Dispensaries, desirous of obtaining it without stamp, must forward their orders direct, duly authenticated, to the manufactory, when they can be supplied in bulk, a liberal discount being allowed.

Price 3s. per ounce, and in quantity of 10 ounces carriage free.

Sole Agent and Manufacturer—J. T. DAVENPORT, Operative and Pharmaceutical Chemist,
33, GREAT RUSSELL-STREET, BLOOMSBURY-SQUARE, LONDON.

Blancard's Pills of Unchangeable IODIDE OF IRON,

Recommended by the Academy of Medicine of Paris,
And authorised by the Medical Council of St. Petersburg,
Extensively tried in the Hospitals of France, Belgium, Ireland, Turkey, &c.
Favourably noticed at the Universal Exhibition of New York, 1853,
and Paris, 1855.

"Of all the modes hitherto proposed of administering iodide of iron in the pure state, I think Mr. Blancard's the best."—Chemistry applied to Therapeutics, by M. Mialhe, Deputy-Professor to the Faculty of Medicine of Paris, Pharmacien to the Emperor, 1856, p. 319.

These Pills stand now very high in the therapeutics of every country, as may be seen by the above quotations, and also by the numerous scientific articles in medical periodicals and works (a).

Being enveloped in a very thin resino-balsamic coating, they present the great advantage of not being liable to any deterioration, of having no taste, of being small, and not distressing the stomach. As they possess the properties both of iodine and iron, they are especially beneficial in chlorotic, scrofulous, tubercular, or cancerous affections, as also in leucorrhœa, amenorrhœa, anæmia, &c. &c., and they furnish the medical man with an excellent means of modifying lymphatic, feeble, and debilitated constitutions. Dose, 2 to 4 pills a day.

N.B.—Impure or altered Iodide of Iron is an unsafe remedy, and may even prove dangerous. Only such bottles as bear an electro-plated seal fixed to the lower part of the cork, and the signature of the inventor placed on a green label, are to be considered as prepared by Mr. Blancard. The public should beware of spurious imitations.

To be had at M. BLANCARD'S, Pharmacien, Rue Bonaparte, No. 40, Paris. General dépôt in England at M. Gabriel Jozéau's, French chemist, 49, Haymarket, London. In Ireland, at Mr. Vitties, Stevens's Hospital, Dublin. In the United States, at E. and S. Fougere, Chemists, 30, North William-street, New York. To be obtained retail from the principal Chemists.

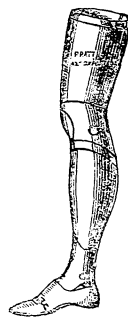

(a) Bulletin de l'Académie de Med 1850, page 1015; Gazette Médicale, Aug. 17, 1850; Union Médicale, Aug. 15 and 22, 1850; Gazette des Hôpitaux, March 15, 1853, and June 10, 1854; Gazette Hebdomadaire de Médecine et de Chirurgie, Aug. 31, 1855; Revue de Thérapeutique Médico-Chirurgicale, Feb. 15, 1855; Abeille Médicale, Revue Clinique; Répertoire de Chimie et de Pharmacie; Annuaire de Thérapeutique pour 1851, page 199; Orfila, Elements of Chemistry; Mialhe, Chemistry applied to Therapeutics, 1856, p. 319; Quevenne, Essay on the Physiological and Therapeutical Action of Preparations of Steel, page 97, 1854; Bricheteau, Treatise on Chronic Diseases seated in the Respiratory Organs; Soubeiran, Treatise on Pharmacy; Dorvault, Officine, &c. &c.

From Dr. J. H. SHORTHOUSE, Carshalton,

Late Physician to the Metropolitan Convalescent Hospital.

I have been in the habit of prescribing Chlorodyne daily for the last twelve months, and beg to express my conviction of its efficiency as a powerful and unique remedial agent. It possesses Anodyne, Astringent, and Anti-spasmodic properties in a remarkable degree.

In all cases of Irritability in which I have tried it, it has induced a state of complete tranquillity and repose. In Phthisis, it has allayed the harassing cough, and diminished the amount of expectoration. In Neuralgia and Rheumatism, it has subdued the pain in a very satisfactory manner. Its effects are totally dissimilar to those of Opium or of any other medicine used in England. In Paroxysmal Coughs from Laryngitis, Croup, Hooping-cough, &c. and in Bronchitis, with copious expectoration, Chlorodyne is superior to any other remedy I am acquainted with. It is also a most efficient Astringent in almost all forms of Hæmorrhage, Hæmoptysis, Hæmaturia, Uterine Hæmorrhage, &c. I have tested its efficacy, and am satisfied with the result. In the case of one gentleman, who, in addition to having a large cavity in the left lung, was also suffering from Diabetes, I prescribed Chlorodyne five months ago; the sugar almost immediately ceased to be passed off by the kidneys, nor has it at any time since appeared in any appreciable quantity, and he may now be considered perfectly well, quoad the Diabetes. The Cough, which before was very troublesome, is now very insignificant. The Hæmoptysis, which had been previously very profuse, has since entirely ceased, and the patient may be considered progressing satisfactorily. He has some knowledge of medicine, and of the effects of different drugs, and he always speaks of his state, after the administration of a dose of Chlorodyne, as a most tranquil and happy one, even when sleep does not follow. He has a perfect intolerance of Opium, and cannot take it in any form or quantity.

Pratt's Artificial Leg.

J. PRATT begs to call the attention of the Profession to the following Testimonial, just received:—

"Somerset,

June 20th, 1858.

"DEAR SIR,—It affords me much pleasure in being able to state that the Artificial Leg which you supplied me with is far beyond my best anticipations. From its being so LIGHT in WEIGHT, and its action in the foot so natural, I can walk, or ride on horseback, with ease and comfort; and few indeed would detect it as being other than natural. It has given me full satisfaction.

I am, dear Sir, yours very truly,
J. W.

To Mr. J. Pratt,
Surgical Instrument Maker,
420, Oxford-street."

THE MEDICAL TIMES AND GAZETTE.

THE BRITISH MEDICAL JOURNAL.

THE MEDICAL CIRCULAR.

EDINBURGH MEDICAL JOURNAL.

THE DUBLIN HOSPITAL GAZETTE.

It is suited to all cases of delicate skin (whether arising from disease or otherwise), and is admirably adapted for nursery use. May be had of all respectable Chemists, Perfumers, &c.

SOAP-WORKS, CLERKENWELL, LONDON, E.C.

NEPENTHE, OR ANODYNE TINCTURE

(OBTAINED EXCLUSIVELY FROM OPIUM),

PREPARED AT THE LABORATORY OF FERRIS, TOWNSEND, LAMOTTE, & BOORNE,
MANUFACTURING CHEMISTS AND WHOLESALE DRUGGISTS, BRISTOL.

This preparation has now been for many years extensively used by a large number of eminent members of the Medical Profession with the greatest success. It does not produce headache, stupor, giddiness, prostration of strength, constipation, or the usual unpleasant symptoms attending the use of other preparations of opium.

NEPENTHE HAS FREQUENTLY BEEN FOUND OF ESSENTIAL SERVICE IN CASES OF CANCER, WHERE EVERY OTHER OPIATE HAS FAILED.

The following Testimonials received from Medical gentlemen in extensive practice will be regarded as satisfactory proof of its efficacy:—

MEDICAL TESTIMONIALS.

"Having prescribed your 'Anodyne Tincture' in many cases, I would strongly recommend its more general adoption. It is especially useful in the wakefulness common after parturition, or other unusual exertion or excitement. It produces a refreshing sleep, and I do not remember any case in which it has caused the objectionable effects of the other opiate preparations."

"SAML. GRIFFITH, M.D. London, M.R.C.P.
Consulting Physician-Accoucheur to the Farringdon Dispensary,
Physician-Accoucheur to St. Thomas's Hospital, &c."

"Ipswich, March, 1859.

"Gentlemen,—I have great satisfaction in bearing testimony to the value of your 'Nepenthe,' in relieving suffering from disease, and in procuring sleep where ordinary narcotics fail or disagree. For several months I have found it very effectual in relieving a great sufferer when all the ordinary anodynes had ceased to benefit, and although the dose has not been increased for months, the relief is as complete.

"'Nepenthe' is a very valuable addition to our means of relief, and the Profession and the public are greatly your debtors for it.

"I am, Gentlemen, yours obediently,

"EDWD. BECK, M.D. Cantab.
Physician to the East Suffolk Ipswich Hospital."

"Portland-place, Reading, Nov. 21, 1856.

"To Messrs. Ferris & Co.
"Gentlemen, 'Nepenthe' has, for some time, been a favourite narcotic with me, and I infinitely prefer it to any preparation of opium now extant. It has proved a remedy of great value in all cases of Neuralgia, Chronic Rheumatism, Hypochondriacism, and indeed all affections where the use of a sedative is indicated; and in Delirium Tremens it is certainly invaluable, performing its operation upon the system, without leaving those distressing feelings consequent upon the use of opiates in general.

"I remain, Gentlemen, your obedient Servant,

"WILL. WOOD BRADSHAW, M.D. M.R.C.P. & F.R.C.S. Lond. &c. &c. &c."

Extract of a Letter from the late G. W. CAINES, Esq. M.R.C.S.

"Uffculme (Devon), Feb. 16, 1854.

"Please to send me some 'Nepenthe,' as I have a patient with cancer in the breast, with whom no other preparation of opium agrees. I have tried them all."

NEPENTHE may be procured direct from Messrs. FERRIS and CO., 4 and 5, Union-street, Bristol; from respectable Dispensing Chemist

throughout the Kingdom; and from the following Agents:—
LONDON:—Mr. Thos. Keating, 79, St. Paul's-churchyard; Messrs. Evans, Lescher, and Evans, 60, Bartholomew-close; Messrs. Savory and Moore, 143, New Bond-street; Messrs. J. Bell and Co., 338, Oxford-st.
MANCHESTER:—Mr. James Woolley.
LIVERPOOL:—Messrs. Clay and Abraham; Messrs. Evans, Son, and Co.; Messrs. Clay, Dod, and Case.

BIRMINGHAM:—Messrs. Southall Bros. and Co.

YORK:—Messrs. Butterfield, Clarke and Co.

NORWICH:—Messrs. Smith and Sons.

PLYMOUTH:—Messrs. Balkwill and Co.

EXETER:—Mr. Geo. Cooper; Messrs. A. Evans and Co.

EDINBURGH:—Messrs. Raines and Co.

As many imitations of Nepenthe have been attempted, the signature of FERRIS and COMPANY is placed over the cork of every bottle of the true preparation; and none purchased without this protection can be depended upon.

Wood and Watson's South African

Scammony Manufactured from the

ROOT.—This Pure Resin may be had of all Wholesale Druggists at 28s. per lb.

The Medicinal value of this Scammony was fully explained at a meeting of the Pharmaceutical Society, and reported at length in their journal of March last, from which the following are extracts:—

"From these numerous observations, one hundred and twenty in number, together with many others which have not been tabulated, I am quite convinced that the scammony prepared by the new process from the untapped root is quite equal, as a remedy, to the very best virgin scammony which is met with in commerce, and equal, in fact, to the resin which is extracted from commercial scammony by means of ether; and it possesses this most important advantage over the scammony of commerce, namely, of being entirely free from the frauds which are almost constantly practised upon it in the country where the plant grows, and in which it has hitherto been collected, and, therefore, being perfectly uniform in its physical characters, composition and therapeutic action. There can, therefore, be no objection, but, on the other hand, manifest advantage, in employing it in place of the scammony commonly met with.

"A. B. GARROD, M.D., F.R.S., F.R.C.P.

"Professor of Materia Medica, Therapeutics and Clinical Medicine at University College; Physician to University College Hospital."

"I have endeavoured to ascertain the relative activity of Messrs. M'Andrew's scammony, and of a fine specimen of commercial virgin scammony, by prescribing these drugs alternately in equal doses to the same patient. The results, according to the judgment of myself and others who have assisted me in watching the cases, is that in most instances Messrs. M'Andrew's scammony has proved itself decidedly more active than the virgin scammony. As to pleasantness of operation, or the reverse, there seemed to be no choice between the two specimens.

"That a preparation of scammony should be a little more or a little less active is of comparatively small importance. It is far more important that the drug should have a fixed and uniform composition and activity, so that the prescriber may know, with an approach to certainty, what doses are required to produce a given effect. This advantage of uniform activity Messrs. M'Andrew's scammony seems likely to possess over the scammony which has hitherto been in common use, and which is a drug notoriously of most uncertain composition and power.

GEORGE JOHNSON, M.D., F.R.C.P.

Professor of Materia Medica and Therapeutics in King's College; Physician to King's College Hospital.

Davis and Kidder's Patent Magneto-

ELECTRIC MACHINES.—This most invaluable Instrument for Medical purposes requires no acid, is portable, always ready for use, and is not liable to get out of order. To be had of J. COXETER, 23, Grafton-street East, London, W.C.

W. F. Durroch, Surgical Instrument

MAKER to the Royal Navy and Greenwich Hospital, respectfully informs the Profession that he continues to MANUFACTURE SURGICAL INSTRUMENTS of every description, of the best quality and highest finish, to which are applied all the improvements introduced by the first authorities of the day. The patronage and approval of the most eminent practitioners and lecturers warrant him in assuring gentlemen who may honour him with their commands that all his instruments will be found highly adapted for the purposes designed. Established 1748. No. 2, New-street, St. Thomas-street (near the Hospital), South-wark.

WINES FROM SOUTH AFRICA.**Denman, Introducer of the South**

AFRICAN PORT, SHERRY, &c. 20s. PER DOZEN, BOTTLES INCLUDED. A PINT SAMPLE OF EACH FOR 24 BOTTLES. Wine in cask forwarded free to any Railway-station in England.

(Extract from the Lancet, July 10, 1858.)

"THE WINES OF SOUTH AFRICA.—We have visited Mr. Denman's stores, selected in all eleven samples of wine, and have subjected them to careful analysis. Our examination has extended to an estimation of their bouquet and flavour, their acidity and sweetness, the amount of wine stone, the strength in alcohol, and particularly to their purity. We have to state, that these wines, though branded to a much less extent than Sherries, are yet, on the average, nearly as strong; that they are pure, wholesome, and perfectly free from adulteration; indeed, considering the low price at which they are sold, their quality is remarkable."

EXCELSIOR BRANDY, Pale or Brown, 16s. per gallon, or 30s. per dozen. Terms Cash. Country orders must contain a remittance. Cross cheques "Bank of London." Price Lists, with Dr. Hassall's analysis, forwarded on application.

JAMES L. DENMAN, 65, Fenchurch-st., corner of Railway-place, London.

Newbery's Cod-Liver Oil Cakes.—

"The gingerbread is extremely light and pleasant, the flavour of the oil being completely covered."—Medical Times and Gazette, 12th February, 1859. Packets, 1s. 9d. and 3s. F. For the demonstration of this new system, vide the Second Edition, price 1s., 8vo, of Dr. Caplin's Treatise on the Electro-Chemical Bath, and the Relation of Electricity to the Phenomena of Life, Health, and Disease. Sold at the Author's Establishment.

Superphosphate of Iron and Super-

PHOSPHATE OF IRON and LIME. New Remedial Agents introduced to the notice of the Profession at the Meetings of the Medical Society of London, and now extensively employed by the most eminent members of the Medical Profession. The Syrup is the most eligible mode of administering these valuable Remedial Agents. Mr. GREENISH will be happy to forward a variety of cases which have been furnished to him, where its success has been most marked, and which will serve to indicate where it may be most advantageously employed.—20, New-street, Dorset-square.

Pepsine.—M. Boudault begs to state

that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, her Majesty's Chemist, 277, Oxford-street, London, to whom all applications respecting it must be addressed.

Second Edition of Boudault on "Pepsine," with Remarks by English Physicians. Edited by W. S. SQUIRE, Ph. D., published by J. Churchill, London, may be also had of the Author, 277, Oxford-street, price Sixpence.

NO LIVE STOCK ON BOARD SHIP.**Joints of Beef and Mutton, also Poultry,**

are now Preserved by HAND'S PATENT. That they will keep quite fresh in an uncooked state in all climates, and when eaten cannot be known from fresh-killed food, cooked meat need not now be taken.

For prices or samples apply to Mr. HESKETH S. DAVIS, 24, Leadenhall-street, London, E.C.

Crosse and Blackwell, Purveyors in

Ordinary to Her Majesty, respectfully invite attention to their PICKLES, Sauces, Tart Fruits, and other table delicacies, the whole of which are prepared with the most scrupulous attention to wholesomeness and purity. The practice of colouring pickles and tart-fruits by artificial means has been discontinued, and the whole of their manufactures are so prepared that they are not allowed to come in contact with any deleterious ingredient. A few of the articles most highly recommended are, Pickles and Tart Fruits of every description, Royal Table Sauce, Essence of Shrimps, Soho Sauce, Essence of Anchovies, Jams, Jellies, Orange Marmalade, Anchovy and Bloaters Pastes, Strasbourg and other Potted Meats, and Calf's-Foot Jellies of various kinds for table use. C. and B. are also sole agents for M. Soyer's Sauces, Relish, and Aromatic Mustard; and for Carstairs' Sir Robert Peel's Sauce, and Payne's Royal Osborne Sauce. The above may be obtained of most respectable Sauce Vendors throughout the United Kingdom; and Wholesale of

CROSSE and BLACKWELL, 21, Soho-square.

King's College, London.—Medical

DEPARTMENT.—The WINTER SESSION, 1859-60, will commence on SATURDAY, OCTOBER 1, 1859, on which day all students are expected to attend the Introductory Lecture, at Two o'clock.

The following Courses of Lectures will be given:—

Anatomy—Professor Richard Partridge, F.R.S.
Physiology; General and Morbid Anatomy—Professor Lionel S. Beale, M.B.
Chemistry—Professor W. A. Miller, M.D. F.R.S.
Principles and Practice of Medicine—Professor George Budd, M.D.
Principles and Practice of Surgery—Professor William Fergusson, F.R.S.

KING'S COLLEGE HOSPITAL.

Physicians... { George Budd, M.D. F.R.S.
R. B. Todd, M.D. F.R.S.
George Johnson, M.D.
W. A. Guy, M.B. F.R.S.
Lionel S. Beale, M.B. F.R.S. } With care of In-Patients.
With care of Out-Patients.

Physician for Diseases of Women and Children and Physician-Accoucheur—Arthur Farre, M.D. F.R.S.

Assistant-Physicians—Charles Murchison, M.D.; Conway Evans, M.B.

Surgeons ... { W. Fergusson, F.R.S.
Richard Partridge, F.R.S.
William Bowman, F.R.S.
Henry Lee, F.R.C.S. ... } With care of In-Patients.
With care of Out-Patients.

Assistant-Surgeons—John Wood, F.R.C.S.; John W. Hulke, F.R.C.S.

Surgeon-Dentist—S. Cartwright, jun.

The Hospital is visited daily. Clinical Lectures are given every week, both by the Physicians and by the Surgeons. The Physicians' Assistants and Clinical Clerks, the House-Surgeons and dressers, are selected by examination from the Students of the Hospital.

SCHOLARSHIPS.—New Students will have the privilege exclusively of contending, in October, 1859, for five Warneford Scholarships—viz., two of £25 per annum, for three years, and three of £25 per annum, for two years. The Examination will commence on the 29th of September, in Divinity, Classics (subjects the same as for the Matriculation Examination this year at the University of London), Mathematics, History, and the Modern Languages.

One Scholarship of £40, tenable for two years; one of £30, for one year; and three of £20 each, for one year, will be filled up in April next, the subjects of the Examination being exclusively Medical.

Further particulars may be obtained from J. Harley, Esq., Sub-Dean of the Department; and a detailed Prospectus will be forwarded by application to J. W. Cunningham, Esq., Secretary.

R. W. JELF, D.D., Principal.

York County Hospital.—A Special

COURT OF TRUSTEES AND GOVERNORS of this Charity will be held at the Hospital, on TUESDAY, the 26th of JULY next, at One o'clock in the Afternoon, for the Election of a HOUSE-SURGEON. He must be an unmarried man. He will have to reside in the Hospital, and to undertake the whole internal management of it, under the House Committee. The salary is £100 a-year, with board and lodging.

Candidates are requested to send Testimonials to my office, on or before the 9th of July. JOSEH. MUNBY, Secretary.

York, June 21, 1859.

Mr. James Robinson, Dentist, has

REMOVED from No. 7 to No. 5, GOWER-STREET, Bedford-square, London, where he may be CONSULTED daily from 10 to 4.
5, Gower-street, Bedford-square.

Varicose Veins and Supporting Bands.

—SURGICAL ELASTIC STOCKINGS AND KNEE CAPS, previous, light in texture, and inexpensive, yielding an efficient and unvarying support, without the trouble of lacing. Likewise, a strong low-priced article for Hospitals and the Working-Classes. ABDOMINAL SUPPORTING BANDS for both Sexes; those for Ladies' use, before and after accouchement, are admirably adapted for giving adequate support with extreme lightness—a point little attended to in the comparatively clumsy contrivances and fabrics hitherto employed. Instruction for measurement and prices on application, and the articles sent by post from the Manufacturers and Inventors, POPE and PLANTE, 4, Waterloo-place, Pall-mall, London, S.W.

The Profession, Trade, and Hospitals, supplied

Students' Achromatic Microscopes.—

C. BAKER, 243 and 244, HIGH HOLBORN, begs to inform the Profession that having introduced improved machinery, he is now enabled to supply a superior ACHROMATIC MICROSCOPE suitable for all Physiological Investigation at the very low price of £3 3s.: they have quick and slow motion, a 1-inch, 3-inch, and 4-inch object glasses, together with all the necessary apparatus packed in a neat mahogany case complete.

Students and others requiring a really practical instrument at a moderate charge are strongly recommended these, as they answer all the purposes of the more expensive kind.

Catalogues by post free upon application.

The Profession are respectfully

informed, that the WANDLE FELT COMPANY having purchased Mr. MARKWICK'S PATENT for the well-known SPONGIO PILINE, for the application of moist heat, in lieu of Poultices and Fomentations, and the IMPERMEABLE PILINE, for Rheumatism, for promoting perspiration, and for the application of stimulating liniments, are now supplying these articles, of superior manufacture, and at greatly reduced prices, at 27, BEDFORDBURY, COVENT-GARDEN, London, and also through the Wholesale and Retail Druggists in town and country.

Or SACCHARATED CAPSULES, approved of by the French College of Physicians, successfully administered in the Paris and London Hospitals, and acknowledged by them to be the best remedy for the cure of certain diseases. (See the "Lancet" of 6th November, 1852; "Medical Times" 10th December, 1852; a copy of which will be forwarded on application.) Price per 100, 4s. 6d.; 50, 2s. 9d.

To be had of the Inventor, GABRIEL JOZEAU, sole French Chemist, 49, Haymarket, London, whose name is printed on the Government stamp, and of all the principal Chemists of England.

Mr. Howard, Surgeon-Dentist, 52,

FLEET-STREET, has introduced an entirely NEW DESCRIPTION OF ARTIFICIAL TEETH, fixed without Springs, Wires, or Ligatures. They so perfectly resemble the natural teeth as not to be distinguished from the original by the closest observer; they will NEVER CHANGE COLOUR or DECAY, and will be found very superior to any teeth ever before used. This method does not require the extraction of roots, or any painful operation, and will give support and preserve teeth that are loose, and is guaranteed to restore articulation and mastication; and that Mr. Howard's improvements may be within the reach of the most economical, he has fixed his charges at the lowest scale possible. Decayed Teeth stopped and rendered sound and useful in mastication. 52, Fleet-street. At home from Ten till Five.

Voullion's Patent Elastic Spiral

SUPPORTS, "WITHOUT SEAMS OR LACING."

200 Leading Members of the Medical Profession recommend them in preference to all others.

DIRECTIONS FOR MEASUREMENT:—

For STOCKINGS—Circumference round the instep, ankle, calf, and above calf.

For KNEE-CAPS—Circumference below knee, at knee, and above knee.

For THIGH-PIECE—Circumference round top and bottom of thigh.

For ABDOMINAL SUPPORTS—Circumference of body above and below the hips.

Illustrated and Priced Catalogues free. Prices reduced 30 per cent.

MEACHER, Operative Chemist, sole Manufacturer, 105, Crawford-street, Portman-square.

Struve's Seltzer, Marienbad, Vichy,

KISSINGEN, and other MINERAL WATERS.—Under her Majesty's especial Patronage.—ROYAL GERMAN SPA, BRIGHTON, STRUVE'S PUMP-ROOM and PROMENADES, offering every facility for a Course of Mineral Waters, as perfect and beneficial as at the natural springs, are NOW OPEN, for the Thirty-fifth Season. A prospectus, with the highest Medical testimonials, may be obtained gratis, at the Pump-room, or from George Waugh and Co. Chemists to the Queen, 177, Regent-street (west side), London, and other respectable houses in London and the provincial towns, where orders for Struve's Bottled Mineral Waters continue to be executed.

CAUTION.—The success obtained by Struve's Mineral Waters, owing to their perfect identity with those of the natural springs, has induced several parties to attempt imitations, sold as "Brighton Seltzer," "Brighton Vichy," &c., an analysis of some of which has shown an utter disregard of their true chemical composition. To distinguish Struve's Waters from all others, every bottle has a label and red ink stamp over the cork, each bearing Struve's name, without which name none is genuine, though contained in Struve's old bottles.

Pillischer's Achromatic Microscopes.—

To meet the daily increasing demand for his Microscopes, M. PILLISCHER has recently completed extensive alterations in his workshops to enable him to manufacture MICROSCOPES and their Object Glasses upon a more expeditious and extensive scale. M. P. has the pleasure of informing the Profession that he is now able to furnish Microscopes of the very greatest perfection; possessing every modern improvement; and with Object Glasses of a quality unsurpassed by any other maker, on the shortest notice, and at very moderate prices.

PILLISCHER'S £7 7s. STUDENTS' MICROSCOPE,

for which a prize Medal was awarded to him at Paris Exhibition, 1855, deserves particular notice. It consists of a well-constructed Stand, with coarse and fine movement on capital Stage, with Diaphragm and Large Mirror, one Eye-glass, a one and one quarter inch Object Glasses, 16" and 75" angular aperture, a neat Mahogany Case about 7 in. square. The above Microscope when further completed with the addition of a Second Eye-glass, Condenser for Opaque Objects, Live Box, Stage Forceps, large Glass Stage, and Polarising Apparatus, price £10, forms a most complete and valuable Microscope, and in every respect as useful as a much more expensive one.

A Catalogue post free on application to M. Pillischer, 33, NewBond-st. W

MEDICAL AGENCY OFFICES,

50, LINCOLN'S-INN-FIELDS, NEAR THE COLLEGE OF SURGEONS.

Mr. Bowmer, M.R.C.S., continues to

assist Gentlemen in the SALE and PURCHASE of PRACTICES, NEGOTIATION of MEDICAL PARTNERSHIPS, and other matters of a confidential nature connected with the Profession. The Monthly Medical Register, containing a descriptive outline of nearly One Hundred Practices, may be obtained free on application, or by post, for two stamps. PRINCIPALS provided with ASSISTANTS (if for a permanency) free of charge.

A First-class unopposed Country

PRACTICE, situated in a rich and highly cultivated Agricultural District, is for TRANSFER. The receipts, on an average of the last five years, exceed £700 per annum. A Partnership introduction of twelve months can be arranged. Premium £1000. Apply to Mr. Bowmer, 50, Lincoln's-inn-fields, W.C.

London.—Hyde Park.—A General

PRACTICE in this neighbourhood, realising £500 a-year, can be immediately arranged. A good introduction will be given. Apply to Mr. Bowmer, Medical Agent, 50, Lincoln's-inn-fields, W.C.

General Practice.—£1800 per annum.

A PARTNERSHIP INTRODUCTION of two years, with ultimate Succession, may be entered on by an active and duly qualified Practitioner desirous of acquiring a first-rate Practice. The Town in which the Practice is conducted contains upwards of 70,000 inhabitants. Apply to Mr. Bowmer, 50, Lincoln's-inn-fields, W.C.

Surrey.—An unopposed Practice,

realising, with Appointments, about £600 a-year, is for IMMEDIATE DISPOSAL. A good introduction will be given. Part of Premium may remain on approved security. Apply to Mr. Bowmer, 50, Lincoln's-inn-fields, W.C.

Lunatic Asylum.—In a First-class

Metropolitan Establishment, the HALF SHARE, with Medical Superintendence, is for IMMEDIATE NEGOTIATION. Apply to Mr. Bowmer, 50, Lincoln's-inn-fields, W.C.

London.—A Select General Practice,

situated in a fashionable West-end Suburb, can be TRANSFERRED by a Partnership arrangement. Present income, £500 a-year. Apply to Mr. Bowmer, 50, Lincoln's-inn-fields, W.C.

A General Practice, situated in a

delightful part of the County of HERTS, and realising an income of £350 a-year, is for TRANSFER. Premium, £350. Apply to Mr. Bowmer, 50, Lincoln's-inn-fields, W.C.

Militia.—A fully-qualified Gentleman

is desirous of being appointed SURGEON to an EMBODIED MILITIA REGIMENT. Address confidentially to M.R.C.S., care of Mr. Bowmer, 50, Lincoln's-inn-fields, W.C.

To Ophthalmic Surgeons.—The

SUCCESSION to the PRACTICE of a CONSULTING SURGEON, in a large Provincial Town (where there are two Hospitals), the appointment to one of which has been held by the Advertiser for many years, may be arranged. Address to M.D., care of Mr. Bowmer, 50, Lincoln's-inn-fields, W.C.

The Nucleus of a respectable Practice

in the immediate locality of BEDFORD-SQUARE is for DISPOSAL. Present receipts about £200 a-year. Apply to Mr. Bowmer, 50, Lincoln's-inn-fields, W.C.

A Gentleman of considerable experience,

and good social and Professional position, who is about retiring from practice, will be happy to make arrangements for assisting, either temporarily or otherwise, a Physician or first-class General Practitioner, in a good part or suburb of London. Apply to Mr. Bowmer, 50, Lincoln's-inn-fields, W.C.

Chymist's Retail.—A Business, in a

Wealthy City in the WEST of ENGLAND, is for prompt DISPOSAL. Returns, £500 a-year. Apply to Mr. Bowmer, 50, Lincoln's-inn-fields, W.C.

Partnership.—One-Third Share of a

highly-respectable GENERAL PRACTICE, in a favourite Watering-place in the County of KENT, is for NEGOTIATION. The returns are about £900 a-year. The succession to the entire Practice may be ultimately arranged. Premium, £500. Apply to Mr. Bowmer, 50, Lincoln's-inn-fields, W.C.

Physician's Practice.—An efficient

INTRODUCTION to an extensive CONNEXION in a POPULAR WATERING-PLACE, much frequented during the season, and containing no other resident M.D., can be immediately arranged. Present average receipts about £450 per annum. Rent, £42 per annum. Premium, £400, and Furniture and Fixtures at a fair valuation. Apply to Mr. Bowmer, 50, Lincoln's-inn-fields, W.C.

London.—A Small General Practice,

in a good class Suburb, and realising between £400 and £500 a-year. In consequence of severe indisposition of the owner, an immediate transfer is necessary. Apply to Mr. Bowmer, 50, Lincoln's-inn-fields, W.C.

To Anatomical Teachers, Lecturers on

Midwifery, &c.—For SALE, an unequalled WAX FIGURE, size of life, by SARTI. It may be dissected to display the whole mechanism of the human frame, including the Gravid Uterus; and is correctly modelled and coloured throughout. Price only 200 guineas.

Apply to Messrs. LARA and WALTERS, 6, Pump-court, Temple, E.C.

A Partnership, or Practice, with

thorough introduction, is REQUIRED, in London, W. by a Married GENTLEMAN, fully qualified, and with considerable experience, who will invest from £1000 to £2000 for a fair equivalent. He would prefer an income at starting of not less than £600 or £700 a-year. Apply, with real name and address (a confidence which will be at once reciprocated), to Medicus, care of Mr. Twinberrow, 2, Edwards-street, Portman-square, W.

Practice Wanted at Christmas.—A

Gentleman, aged 31, married, is desirous of PURCHASING a PRACTICE of from £600 to £800 a-year, in any pleasant neighbourhood near London. Introduction by a Partnership of not less than two years. Or he would take a permanent Partnership of £400 or £500 a-year, with an elderly Practitioner wishing to realise the "otium cum dignitate," by transferring the hard work to a junior. The Advertiser, not being altogether dependent on Professional earnings, is anxious for active occupation in a genteel neighbourhood, rather than for a large income. Cash ready. References unexceptionable.

Apply to Messrs. LARA and WALTERS, 6, Pump-court, Temple, E.C.

A Practice with Pharmaceutical

connexion attached, carried on in a large thoroughfare near the metropolis, is for disposal, with an efficient introduction. The receipts are £800 per annum. Entrance, £700. Apply at Mr. Orridge's Offices, 30, Bucklersbury.

Medical Partnership.—A Gentleman,

duly qualified to take a leading position in an important HIGH-CLASS PRACTICE, may find an unusual opportunity for the profitable devotion of talent and some capital, in a large Suburban Medical Establishment, either with or without water-cure. Particulars may be had of John Dawson and Son, Marlboro' Chambers, 49, Pall Mall.

A General Practice in Cheshire is for

IMMEDIATE DISPOSAL. It has been long established. It produces between £300 and £400 per year, and is steadily increasing. This is an excellent opportunity for a gentleman of practical experience, and of active, and persevering habits, succeeding at once to a good practice. A proper introduction will be given. Address, N. Little Sutton, P. O. Chester. N.B. Appointments to the value of £85 can be secured.

A General Practice, in one of the most

thriving manufacturing towns in Lancashire, is for DISPOSAL, with a PARTNERSHIP INTRODUCTION, the Vendor retiring from practice. Receipts upwards of £800 per annum. Entrance, £400. House, Gig, and contents of Surgery, at a valuation. Address, L. P. Medical Times and Gazette office.

Royal Berks Hospital.—A Competent

DISPENSER is REQUIRED in the ROYAL BERKS HOSPITAL, READING. Salary, £25 a-year, with Board and Lodging. Applications, accompanied by Testimonials, should be sent addressed to the Secretary, at the Hospital, on or before the 25th July, from whom in the meantime, any further particulars may be learned.

Reading, June 28, 1859.

Nervous and Mental Disorders.—Wyke

House, Sion Hill, Islworth, Middlesex, a private establishment for the care and recovery of Ladies and Gentlemen mentally afflicted. Conducted by Mr. ROBERT GARDINER HILL, late Resident Medical Professor of Eastgate House, Lincoln, and by Dr. E. S. WILLETT.

Asylum for the Imbecile and Insane,

at BENSAM, NEAR NEWCASTLE-ON-TYNE. Physician and Proprietor . . . Dr. GEORGE ROBINSON. Resident Physician . . . Dr. DOUGLAS ROBERTSON. There are now SEVERAL VACANCIES in this Institution, which is pleasantly situated, and commands extensive views of the surrounding country. For terms, &c. apply at the Asylum, or to Dr. Robinson, Newcastle.

The Queen's Hospital.—A Meeting of

the GOVERNORS of the QUEEN'S HOSPITAL will be held on FRIDAY, AUGUST 12th, to Elect an ASSISTANT-PHYSICIAN and an ASSISTANT-SURGEON. The Governors are respectfully requested to keep their votes disengaged until the Testimonials of all the respective Candidates are fairly before them. The Testimonials to be sent in under cover, to the Secretary of the Queen's Hospital, on or before Friday, August 5th, 1859. For information respecting the duties of the appointments, application may be made to the Secretary.

DAVID MALINS, Junior Secretary.

Cash Receipts in 1858, £1950; this

Year up to the present time, £1800. This excellent Practice, pleasantly situated in the neighbourhood of London, can be safely TRANSFERRED, with entire receipts from the day of entry, to a well-qualified and energetic young Surgeon, for £2000, half cash, and the rest at six, nine and twelve months. The vendor is retiring from the Profession, but will reside in the neighbourhood, and give any introduction and assistance in nominal partnership, for whatever term may be desired.

Apply to Messrs. LARA and WALTERS, 6, Pump-court, Temple, E.C.

Partnership.—The Half of a First-

CLASS PROVINCIAL PRACTICE, with ULTIMATE SUCCESSION, is OFFERED to a well-qualified gentleman, possessed of between £2000 and £3000 capital.

Apply to Messrs. LARA and WALTERS, 6, Pump-court, Temple, E.C.

£2500.—A fully-qualified gentleman,

not under 30, and with this sum at command, may SUCCEED to a FIRST-CLASS PRACTICE near Town, realising from £1200 to £1500 a year. Usual Midwifery fee £3 3s., and upwards.

Apply to Messrs. LARA and WALTERS, 6, Pump-court, Temple, E.C.

Partnership.—Price £750, the half of

an OLD-ESTABLISHED PRACTICE, in the WEST of ENGLAND, which will give a nett income of from £300 to £400 a-year.

Apply to Messrs. LARA and WALTERS, 6, Pump-court, Temple, E.C.

One, Two, or Three Years' Introduction,

by PARTNERSHIP, will be given to a Practice of over £700 per annum, nearly twenty years established by the Vendor, in a pleasant and rising suburb of London. For the first-named term, £800 will be accepted.

Apply to Messrs. LARA and WALTERS, 6, Pump-court, Temple, E.C.

A Thoroughly Good and Sound

PRACTICE, of between £700 and £800 a-year, in a rapidly increasing town in Yorkshire, with Agricultural neighbourhood, is offered, with contents of Surgery, Horse, Phaeton, and equity of redemption of Handsome and Suitable residence, for £1000, half cash, and the rest at the end of a proper introduction. Rent and taxes would then be little more than £30 per annum.

Apply to Messrs. LARA and WALTERS, 6, Pump-court, Temple, E.C.

Lunatic Asylum.—Wanted, an active

or Sleeping Partner in a HIGH-CLASS ASYLUM near Town. £200 or £300 will give 25 per cent. interest.

Apply to Messrs. LARA and WALTERS, 6, Pump-court, Temple, E.C.

Devon.—£450 per annum in this

favourite county for One Year's purchase. Six months' introduction by partnership will be given. About £100 in the twelvemonth ready money. There is only one opponent, and journeys do not average more than 10 miles daily. Pleasant society, and good hunting and fishing.

Apply to Messrs. LARA and WALTERS, 6, Pump-court, Temple, E.C.

Lunatic Asylum Partnership.—A

GENTLEMAN suitably qualified, may receive HALF the PROFITS (now amounting to £1500 per annum) for his services, and an advance of £2000 on good security; after a year or two's experience, the loan to be converted into the purchase of a moiety by valuation.

Apply to Messrs. LARA and WALTERS, 6, Pump-court, Temple, E.C.

For Immediate Transfer, a Well-esta-

blished PRACTICE in the North of London. Cash receipts, £250 per annum. There is no retail, but the premises are adapted for an Open Surgery, for which the neighbourhood is suited. £250 will purchase the necessary introduction, stock and fixtures, and the entire FURNITURE of an eight-roomed house.

Apply to Messrs. LARA and WALTERS, 6, Pump-court, Temple, E.C.

A Highly Respectable General

PRACTICE in a small Market Town in the West of England, can be TRANSFERRED for one year's purchase of the gross cash receipts—about £400; one quarter being from well-paid appointments. No midwifery under £1 ls. Only one opponent within seven miles. The advertiser leaves to graduate and practise elsewhere as Physician. There is a good house, with a large garden.

Apply to Messrs. LARA and WALTERS, 6, Pump-court, Temple, E.C.

For Disposal, a General Practice,

within a mile from the Strand. Receipts, £300 a-year; but the connexion is a good one, and offers facilities for very considerable increase. Midwifery, £1 ls. and £2 2s.

Apply to Messrs. LARA and WALTERS, 6, Pump-court, Temple, E.C.

Practice wanted, in some pleasant

locality near London. Receipts should be from £400 to £800 a-year, with scope for increase, and the advertiser, having some standing, would prefer only a short introduction, and to pay accordingly. Cash ready.

Apply to Messrs. LARA and WALTERS, 6, Pump-court, Temple, E.C.

Medical Transfer and Partnership.

30, Bucklersbury, Cheapside.

Mr. Orridge, Medical Transfer Agent,

Referee, and Valuer of Medical Property, may be consulted, at the above Address, by Gentlemen about to receive PARTNERS, or to RELINQUISH or to COMMENCE Practice.

Mr. Orridge is known to many of the Hospital Physicians and Surgeons of London; and has been concerned professionally for a large proportion of the most influential Practitioners, including Partners in many of the leading Medical Firms.

On occasions where advice is required in forming a correct conclusion as to the worth or eligibility of a Practice, Mr. Orridge hopes that his familiarity with the various contingencies that govern value will be found of considerable service to those by whom he is employed.

Mr. Orridge wishes to direct the attention of those who are in the habit of employing more than one Agent to effect the same object, to the remarks of Lord St. Leonards, in his "Handy Book," on the inexperience of such a course. He ventures to remark, that HALF-CONFIDENCES ARE ALWAYS OBJECTIONABLE; and that no one having a property of genuine character to dispose of, should endanger its value by needless publicity.

Gentlemen desirous of obtaining Mr. Orridge's opinion, or requiring his attendance professionally in any part of England, can obtain terms on application, by (confidentially) transmitting name and address.

Office Hours, from Eleven to Four.

Medical Assistants.—Gentlemen who

require assistance, and think fit to remit One Guinea to Mr. Orridge, 30, Bucklersbury (as a subscription for the year), can have the addresses of Assistants requiring engagements transmitted on application.

Medical Assistants, Visiting and

DISPENSING.—Assistants are required in various localities. Gentlemen possessing suitable qualifications and satisfactory references can obtain particulars (without fee) by applying at Mr. Orridge's Offices, 30, Bucklersbury. The Advertiser does not undertake to answer WRITTEN communications on the subject.

In a Borough Town, about 50 miles

from London, a GENTLEMAN who is advanced in life, wishes to arrange with a really eligible Practitioner, about twenty-five or twenty-seven years of age, who may be willing to accept a third share for about seven years, and perform the more active duties of the practice. A present payment of £400 would be indispensable as a guarantee of good faith on the part of the income. The business is of considerable magnitude. It is essential that an applicant should possess the double qualification, and be accustomed to horse exercise. Address to DEPT., Mr. Orridge's Offices, 30, Bucklersbury. The Advertiser will only reply to the written applications that appear most suitable.

In a beautiful District of the West of

England, a PRACTICE has been carried on about twenty-five years, in a small town (where there is no opponent), and is now about to be relinquished. The receipts are about £500 yearly. The greater part of the patients reside within three or four miles from the Surgeon's house. Two Horses are required. The premises are in good repair, with ample accommodation, and held at low rent. An effective introduction (by short partnership) can be given, and some considerable appointments opened to a successor. The furniture can be taken by valuation if desired. Entrance, £500. Apply at Mr. Orridge's offices, 30, Bucklersbury.

A Valuable Introduction to a

CONNEXION of great respectability (in one of the best districts of London) very many years in the hands of an eminent Practitioner, now retiring, is TRANSFERABLE, with lease of a large and commodious residence. Entrance, £400. Apply at Mr. Orridge's Offices, 30, Bucklersbury.

A Partnership in a large and wealthy

Market Town about Seventy miles from London (with ultimate succession) is attainable by a well-qualified Practitioner of active habits who can command £1200. The connexion is extensive, and of long standing. Apply at Mr. Orridge's Offices, 30, Bucklersbury.

An Introduction to a Physician's

PRACTICE, in an IMPORTANT TOWN, will be arranged with a Gentleman, holding the M.D. degree and other requisite qualifications. A Graduate of Oxford or Cambridge preferred. Apply at Mr. Orridge's Offices, 30, Bucklersbury.

Required in or near London, a Practice

or PARTNERSHIP, where the share would not be less than £700 to £1000 yearly. The Advertiser is 30 years of age, married, and willing to exchange London references. He has ample means at command for an eligible opportunity. Apply to H. H., Mr. Orridge's Offices, 30, Bucklersbury.

Near London, a General Practice

averaging £550 yearly, is for disposal, with a brief introduction on easy terms. Apply at Mr. Orridge's Offices, 30, Bucklersbury.

London: Printed by CHARLES REED and BENJAMIN PARDON of 1, 2, and 3, Lovell's-court, Paternoster-row, in the City of London, and published by JOHN CHURCHILL, at the Publishing Office, No. 11, New Burlington-street, in the Parish of St. James, in the City of Westminster.—July 2, 1859.

Now ready, in One Vol. 8vo, pp. 370, price 7s. 6d.
A Treatise on Medical Electricity,
Theoretical and Practical; and its Use in the Treatment of Paralysis, Neuralgia, and other Diseases. By J. ALTHAUS, M.D.
Trübner and Co. 60, Paternoster-row.

Just published, in one volume, royal 8vo, pp. 992, handsomely bound in cloth, price 18s.
A Dictionary of Medical Science. By ROBLEY DUNGLISON, M.D. LL.D. Fifteenth Edition, revised and very greatly enlarged.
It reviewing the fourteenth edition of this celebrated work, the "British and Foreign Medico-Chirurgical Review," for July 1853, page 205, remarked, that the labour which had been bestowed upon the work "had been something prodigious," adding, "the work, however, has been now done, and we are happy in the thought that no human being will have again to undertake the same gigantic task. Revised and corrected from time to time, Dr. Dunglison's 'Medical Lexicon' will last for centuries."
Yet, in the present edition, not only has the work been revised and corrected, but about six thousand subjects and terms have been added, which are not to be found in the one noticed by the "British and Foreign."
Trübner and Co., 60, Paternoster-row, London.

Medical Times and Gazette.

Vol. I. for 1859 was concluded on SATURDAY, JUNE 25.
IT MAY BE HAD, BOUND IN CLOTH, PRICE 17s.

THIS VOLUME CONTAINS SIXTEEN CLINICAL LECTURES ON THE DISEASES OF WOMEN, By PROFESSOR SIMPSON.

LECTURE 1.—On Vesico-Vaginal Fistula.

- 2.—On the Treatment of Vesico-Vaginal Fistula (*with eighteen engravings*).
- 3.—On the Pathology, Symptoms, and Diagnosis of Cancer of the Uterus (*with four engravings*).
- 4.—On the Palliative Treatment of Cancer of the Uterus (*with three engravings*).
- 5.—On the Surgical Treatment of Cancer of the Uterus (*with seven engravings*).
- 6.—On the Treatment of Carcinoma of the Uterus and Mamma by Caustics (*with three engravings*).
- 7.—On Dysmenorrhœa (*with four engravings*).
- 8.—On the Treatment of Dysmenorrhœa (*with seven engravings*).
- 9.—On Closures, Contractions, and Fissures of the Vagina and their Treatment.

LECTURE 10.—On Urethral Caruncles—Neuromata of the Vulva—Hyperæsthesia and Neuralgia of the Vulva (*with three engravings*).

- 11.—On Abscess of the Labia Pudendi, and the various forms of Vulvitis.
- 12.—On the Causes of Death after Surgical Operations and Injuries.
- 13.—The Causes and Symptoms of Surgical Fever (*with three engravings*).
- 14.—The Preventive and Curative Treatment of Surgical Fever.
- 15.—The Symptoms, Diagnosis, and Pathology of Phlegmasia Dolens.
- 16.—The Treatment of Phlegmasia Dolens (*with an engraving*).

This Volume also contains THREE LECTURES by Dr. PRIESTLEY on the

DEVELOPMENT OF THE GRAVID UTERUS,

TWO PAPERS by Dr. CONOLLY, with Illustrations of the

PHYSIOGNOMY OF THE INSANE,

LECTURES and ADDRESSES by Sir JOHN FORBES, Professor OWEN, Mr. GREEN, and Mr. PAGET; and Communications from the following Gentlemen:—Acton, Adams, Alison, Althaus, Anstie, Armstrong, Arnott, Atcherley, Aveling, Barclay, Barlow, Barnes, Barry, Brady, Bastick, Braithwaite, Browning, Bruce, Bryce, Buchanan, Buckland, Budd, Bullar, Bulley, Bryant, Cameron, Camplin, Carson, Channing, Chapman, Cheetham, Clark, Corbitt, Cotton, Crawcour, Crondace, Davey, Davies, Dick, Duggan, Dunn, Dymock, Edwards, Evans, Fenwick, Field, Figg, Fleming, Fletcher, Fox, Gallagher, Gamgee, Gay, Gibb, Hewson, Hillier, Hodge, Hornidge, Hoshier, Hulme, Hutchinson, Humble, Holthouse, Hunter, James, Johnson, Jones, Kealy, Keller, Kesteven, Lawrence, Lawson, Laycock, Lee, Leared, Lowes, Lethaby, Lizars, Mackenzie, Marcet, Markham, De Mussy, Monckton, McCraith, McDermott, Maunders, Maysmor, Meadows, Milroy, Moore, Ogle, Parker, Pittard, Prichard, Pollock, Ramsbotham, Richardson, Robinson, Rolleston, Rooke, Rowth, Savery, Scott, Sedgwick, Shaw, Smith, Stallard, Statin, Taylor, Toynbee, Turner, Tuson, Wade, Waller, Walton, Wells, Wilde, Williamson, Wood, Wright, Young, &c.

Just published, crown 8vo, 1s.

On Primary and Secondary Syphilis of the UTERUS. By LANGSTON PARKER, M.R.C.S., Surgeon to the Queen's Hospital, Birmingham.

T. Richards, 37, Great Queen-street, Lincoln's-inn-fields.
Birmingham: Cornish Brothers.

ELECTRICITY IN DENTAL OPERATIONS.

The Dental Review, for July, price

One Shilling, contains a full Report of the Committee appointed to test the value of Electricity as an Anæsthetic, presented at a Meeting of the College of Dentists, June 7th, 1859—Editorial Article—A Charter for Dentists—Irrregularities of the Permanent Teeth (with illustrations), by J. Robinson—On the Development of the Teeth and Jaws, by M. Natilis Guillon, translated from the French by R. T. Hulme, F.R.S. with illustrations—Historical Review of Dental Surgery (with illustrations), by A. Hockley—Dr. Richardson's Eighth Lecture on "The Medical History and Treatment of Diseases of the Teeth."—Obituary, &c.

London: H. Baillière, 219, Regent-street, W.

BEST POPULAR BOOK ON THE MICROSCOPE.

In post 8vo, 6s. cloth extra,

The Microscope, its History, Construction, and Application. By JABEZ HOGG, Esq. The Fourth and newly revised Edition, with Five Hundred Engravings.

"The experienced microscopist will find in it not only much that is new to him, but hundreds of descriptions and engravings of objects that, some time or other, have occupied his attention; whilst the general reader will find in it much instructive information. Altogether it is a deservedly popular work, and one which should be found on the shelves of every well-furnished library."—The Lancet.

London: Routledge, Warne, and Routledge, Farringdon-street.

Superphosphate of Iron and Super-

PHOSPHATE OF IRON AND LIME. New Remedial Agents introduced to the notice of the Profession at the Meetings of the Medical Society of London, and now extensively employed by the most eminent members of the Medical Profession. The Syrup is the most eligible mode of administering these valuable Remedial Agents. Mr. GREENISH will be happy to forward a variety of cases which have been furnished to him, where its success has been most marked, and which will serve to indicate where it may be most advantageously employed.—20, New-street, Dorset-square.

NO LIVE STOCK ON BOARD SHIP.

Joints of Beef and Mutton, also Poultry,

are now Preserved by HAND'S PATENT. That they will keep quite fresh in an uncooked state in all climates, and when eaten cannot be known from fresh-killed food, cooked meat need not now be taken.

For prices or samples apply to Mr. HESKETH S. DAVIS, 24, Leadenhall-street, London, E.C.

Great Reduction in the Prices of New

MEDICAL GLASS BOTTLES and PHIALS, at the Islington Glass Bottle Works, Islington-place, Park-road. London Warehouses, 19, Bread-street-hill, near Thames-street, City, E.C., and 2, Upper Copenhagen-street, Bamsbury-road, Islington. E. and H. HARRIS and CO. Proprietors.

Immediate attention to country orders. No remittance required until the goods are received. Packages free. Goods delivered free within 7 miles. Post-office orders made payable to E. and H. HARRIS and Co., at the Chief Office, London. Bankers: Union Bank of London.

N.B.—Orders sent to either Establishment will have prompt attention.

Struve's Seltzer, Marienbad, Vichy,

KISSINGEN, and other MINERAL WATERS.—Under her Majesty's especial Patronage—ROYAL GERMAN SPA, BRIGHTON, STRUVE'S PUMP-ROOM and PROMENADES, offering every facility for a Course of Mineral Waters, as perfect and beneficial as at the natural springs, are NOW OPEN, for the Thirty-fifth Season. A prospectus, with the highest Medical testimonials, may be obtained gratis, at the Pump-room, or from George Waugh and Co. Chemists to the Queen, 177, Regent-street (westside), London, and other respectable houses in London and the provincial towns, where orders for Struve's Bottled Mineral Waters continue to be executed.

CAUTION.—The success obtained by Struve's Mineral Waters, owing to their perfect identity with those of the natural springs, has induced several parties to attempt imitations, sold as "Brighton Seltzer," "Brighton Vichy," &c., an analysis of some of which has shown an utter disregard of their true chemical composition. To distinguish Struve's Waters from all others, every bottle has a label and red ink stamp over the cork, each bearing Struve's name, without which name none is genuine, though contained in Struve's old bottles.

ORIGINAL LECTURES.

CLINICAL LECTURES

ON

THE DISEASES OF WOMEN.

By J. Y. SIMPSON, M.D. F.R.S.E.

Professor of Medicine and Midwifery in the University of Edinburgh.

LECTURE XVIII.—ON PELVIC CELLULITIS.

GENTLEMEN,—I intend to direct your attention to-day to a malady which presents to us the following peculiarities in its history; viz. 1st,—It is a disease of great importance, and as all now acknowledge, it is by no means unfrequent in practice; 2nd,—It is an affection which it is in general not at all difficult to detect; yet 3rd,—It is not described, as far as I am aware, in any English systematic work on Midwifery or the diseases of females, published earlier than twenty years ago; and 4th,—Though thus neglected and overlooked by our fathers and their predecessors, it is an affection a full and distinct account of which has been left us in the writings of various old Greek and Roman Physicians. "Probably," observed Aristotle upwards of 2000 years ago, "probably all art and all wisdom have often been already fully explored, and again quite forgotten." The remark at all events strongly applies to many facts in medicine, and among other things to the disease in question. One of the first modern accounts of the disease I refer to, was published in France by Marchal de Calvi, in 1844, under the title of an essay on "Intra-pelvic Phlegmonous Abscesses." This essay was reviewed at the time in the old "Medico-Chirurgical Review." In the very number of the "Medico-Chirurgical Review" in which this essay of M. Marchal de Calvi is reviewed and most highly praised and recommended, the reviewer takes occasion, apropos of the publication by the Sydenham Society of Dr. Adams' admirable translation of Paulus Aegineta, to sneer at the Medical knowledge of the ancient Physicians, and to reprobate in no measured terms the study of the ancient authors. But in that translation of Paulus Aegineta which the reviewer thus affects to despise, there is a very concise and lucid account of the disease, for a treatise on which M. Marchal de Calvi receives so much praise. Various diseases well known to the ancients, and fully described in their writings, have been lost from sight and observation for many ages; so that when detected again in our day they appear in the light of entirely new discoveries. In the time of the Emperor Trajan, there was a physician in very extensive practice in Rome, of the name of Archigenes, who equally with Agathinus has been regarded as the head of the Eclectic School. Juvenal makes frequent reference, to Archigenes, and describes him going about visiting his patients attended by fifty pupils, each feeling every patient's pulse by turns. This same Archigenes left a great many writings. Among the fragments of his writings that have been preserved, one relates to the disease I wish to speak of. If I can lay hold of the account of it which is quoted from him by Ætius, I may perhaps read it to you at my next lecture, in order to show you how much he knew both of the course and treatment of the disease.

Professor Doherty, of Galway, and Professor Churchill, of Dublin, were the first modern English authors who called the attention of the Profession to the frequency and importance of the disease I allude to: the former describing it as "chronic inflammation of the appendages of the uterus after parturition;" and the latter, as "abscess of the uterine appendages." In some observations on uterine diseases published in 1843, after giving some details of two cases of the disease in the puerperal female, I added that, "I had seen several cases in the female of chronic 'pelvic inflammatory tumours,' unconnected with the puerperal state; and where the fixed condition of the body of the uterus, the surrounding tumefaction, and the apparent almost ebony induration produced in the roof of the vagina at one stage of the disease, by the tenseness and distension of the pelvic fascia, gave rise to the idea that the affection was organic and carcinomatous, and not simply inflammatory." We all now know the disease to be far from rare, even in the non-puerperal female; and I

have usually here lectured upon it under the name of Pelvic Cellulitis, a name which I ventured to suggest in consequence of its pathological seat and nature.

We have had two instances of this disease in the wards during the session, and one of the patients is still under observation. Before discussing the subject of Pelvic Cellulitis more at length you will allow me to read to you the history of these two cases from Mr. Sclander's report.

Case 1.—"C. R. admitted Feb. 12, 1859, aged 30, married twelve years. Was very healthy before her marriage; menstruates regularly. Has given birth to six children, and had one miscarriage, which occurred between the fifth and sixth labours. She has had rapid recoveries from all her previous labours, and has been attended by accoucheurs. She had a midwife with her in her last confinement, which occurred two months ago. Had a very short labour, lasting only from 6 a.m. to 9.30 a.m., at which time the placenta was expelled naturally. She remained very well during the first week, and was rapidly recovering; but at the end of the week she had rigors, which have continued at times up till now. She then noticed for the first time pain in the right iliac region and great tenderness on pressure, which was succeeded on the fifth week after delivery by a swelling in the part first affected by pain. This swelling was tense, hard, and circumscribed. Mustard poultices were first applied, and then leeches, and she experienced great relief, although the abdominal swelling remained as painful as ever. The rigors were followed by profuse perspirations whenever they occurred. The pulse rose rapidly from the first symptoms; appetite was much impaired; great thirst, and feeling of weakness and depression.

"On admission, there is a hard swelling in the right iliac region, extending to within a short distance of the mesial line. The space occupied by this hardness is dull on percussion and tender on pressure; and when the finger is introduced into the vagina the internal surface of the swelling may be readily felt—it seems to be uneven and very sensitive. Much feebleness; tongue dry and coated with a whitish fur; lips dry and fissured; expression anxious; respiration natural; pulse 98; urine of natural colour and quantity; bowels regular.

"R. Hydrarg. bichloridi gr. i., aquæ zii., a teaspoonful to be taken three times a-day. To have a blister produced by nitrate of silver.

"Feb. 18.—The tenderness is much lessened; but the swelling remains of the same size and shape.

"19th.—Complains of sickness and pain in the epigastrium. To have—R. Bismuthi trisnitratis ʒss., mucilaginis ʒi., aq. fontis ʒv., a tablespoonful three times a-day.

"23rd.—The sickness and pain have disappeared. The abdominal swelling is lessened, and the patient has not had any rigors since last report. To take Citratis ferri et quinae gr. iii. per day.

"March 2.—There is much hardness and tenderness in the region of Poupart's ligament on the right side. She cannot extend the right thigh in consequence of the excessive pain; the inguinal glands are enlarged and indurated. To have another vesication with nitrate of silver, and to take Syr. ferri iodidi m. xx. ter in die.

"3rd.—There is a purulent discharge from the vagina, noticed principally when the patient empties the bladder. The pain over Poupart's ligament is much better.

"9th.—The purulent discharge still continues, but in diminished quantity. To have unguent. bismuthi applied to the vesicated surface on the groin."

Case 2.—"S. N., aged 21, admitted March 24, 1859. States that she has always enjoyed good health up till the date of the present attack. Menstruates regularly; occasionally observed her feet to swell towards night; but attributed it to her running up and down stairs so much. She attributes her present illness to having caught cold after menstruating, about three weeks ago, at which time also she suffered from diarrhoea. This diarrhoea continued for several days, after which she was seized with pain in the lower part of the stomach, back, and left iliac region. This pain, which has continued up till the time of her admission, is not constant, but more severe generally at night. She describes it as shooting round from the left to the right side and down the left thigh as far as the knee. Pain and tenderness over the lower part of the abdomen. On examination per vaginam, a tumour is felt projecting from the left side, in the situation of

the broad ligament of that side of the size of an egg, hard and firm. Ordered two leeches to be applied round the anus, and Pil. mass. hydrarg. gr. iii.; mitte tales xii. One every four hours, and a starch and opium injection. Fomentations to be applied to the lower part of the abdomen.

"April 3.—Ordered—*R. hydriod. potass. ʒss. syrapi simplicis. ʒi. aquæ fontis ad. ʒviii.* A tablespoonful thrice daily; diet to be light; chicken soup.

"12th.—Patient complains of palpitation, with severe pain in back. Pulse 104. Ordered—*pulv. digitalis gr. vi. potassæ bitart. ʒv. pulv. cinamon comp. ʒi. fiant. pulv. vi.*

"13th.—Pain in the left side worse to-day. The tumour is felt to be increased in size. Ordered to use mercurial pessaries, and tincture of iodine to be painted externally on the lower part of the abdomen.

"17th.—Ordered—*R. ol. crotonis ʒiss., ol. olivæ ʒi. Fiat linimentum.* To be applied every night.

"18th.—To-day she has been unwell; very slight discharge. *R. acidi hydrocyanici dil. ʒss., tinct. hyoscyami ʒss., mist. camphoræ ʒiss. tinct. cardam. comp. ʒss. M. Signa.* A tablespoonful thrice daily.

"20th.—As the discharge still continues scanty, ordered leeches to be applied round the anus.

"23rd.—Catamenia ceased: to return to mixture prescribed April 3rd, and continue the croton liniment.

"25th.—Complains of great pain in the right side, much more than is usual; very restless, and does not sleep.

"29th.—Much better to-day—is going about the ward.

"May 7.—Continues to improve. The tumour on examination is lessened considerably. Ordered *emplast. lyttæ 4 by 4*, to be applied over the left side.

"15th.—Complained of return of pains, very severe to-day. To have tincture of iodine painted externally.

"25th.—Ordered—*R. quinae disulph. gr. xii. acid sulph. dil. ʒxl. aquæ ad ʒviii.* A tablespoonful thrice daily.

"29th.—Ordered—*R. tinct. hyoscy. eth. chlorici ʒā ʒss. mist. camph. ʒss. aquæ ʒi. fiat haustus*, as patient complains of great pain, and has not slept for two nights.

"30th.—Much better to-day. Ordered—*R. hydrarg. iodidi gr. vi. pil. galbani ʒii. divide in pil. xii. Sig. one twice a-day.*"

NOMENCLATURE OF THE DISEASE.

The disease of which you have had an opportunity of studying the phenomena in the patients whose history I have now read to you, has been known under different names, which may be apt to cause you some perplexity in attempting to get at the literature of it. Some of these names I have already stated to you. It was generally described by the ancient writers as "abscess of the uterus;" it has very often been described by modern writers as "pelvic abscess;" but the designation is an incorrect one, for pelvic cellulitis is no more pelvic abscess, than pleuritis is empyema. In the one case as in the other, the inflammatory process which is the primary and original disease, may pass on to its highest grades and lead to the development of pus. In pleurisy, if the inflammation be not checked in time and the membrane be not restored to its normal state pus comes at length to be secreted into the pleural cavity, and the pleurisy merges into empyema. So in the case of inflammation of the different portions of cellular tissue contained within the pelvis, or, in other words, in *Pelvic Cellulitis*, you will find that usually it only merges into "pelvic abscess" when no attempt has been made to subdue the inflammation, or when even well-directed treatment has failed to prevent it from ending in suppuration. In the girl who is still in the ward, there was at one period in the history of her disease a large inflammatory swelling or effusion in the left broad ligament, which was dispersed and disappeared. Since then a similar swelling, or inflammatory effusion, has, as you have been told, become developed between the rectum and the vagina, but instead of ending in resolution as before, the inflammation now proves less amenable to treatment, and threatens to end in suppuration, and to lead to the development of a pelvic abscess.

Again, descriptions of inflammation of the cellular tissue of the pelvis have been overlooked among the accounts of the other inflammations occurring simultaneously with it as the results of unfavourable confinements, or they have been lost among the notices of other sequelæ of unfortunate operations performed on the pelvic organs. You will find cases on

record under the names of "psoas abscess" after delivery, "iliac abscess," etc. We meet the disease most frequently, perhaps, in the case of puerperal patients, who have been subject to injurious influences; but it occurs also frequently, as I have already mentioned to you, in non-puerperal patients as well, as we see in the case of the girl in the ward in whom the disease seems to have been caused by exposure to cold during a menstrual period. It may result from any operations in the pelvis, or injury of the pelvic organs. It may occur in patients of all ages and at all times of life. I have seen it in young female children; and I have attended patients attacked with it when upwards of seventy. It is a disease not confined to women, although most frequently seen and recognised in them. Cases of pelvic cellulitis and abscess occur not unfrequently in the male sex from cold, after operations on the urethra, rectum, etc.

PATHOLOGICAL ANATOMY.

The disease consists essentially and primarily of inflammation of the cellular tissue of the pelvis; and to understand aright its nature and its course, and to be able to construct a proper plan of diagnosis and treatment, we must study,

1. *The Seat of the Inflammation.*—The pelvis, as you know, is lined and closed in inferiorly by means of a fascia, which gives off sheaths to the different pelvic muscles, and furnishes processes for the protection, support, and separation of the various pelvic organs. Wherever two layers of this fascia approach each other after covering the opposite surfaces of any organ or muscle, and wherever two layers covering contiguous organs come to be in opposition, you will find that there is always a greater or less quantity of loose cellular tissue interposed between them. Thus between the layers of the broad ligaments, between the vagina and the rectum between the iliac muscle and the bone, and in short, in almost every part of the pelvis, there is an abundance—a great abundance—of cellular tissue; and, I repeat, the disease of which I have now to speak consists of inflammation, acute or subacute, of this abounding cellular tissue.

2. *The Products and Terminations of this Inflammation* vary according to the stage of the disease, and may be considered under the four following divisions:—

- 1st. Serum;
- 2nd. Pus;
- 3rd. Coagulable Lymph;
- 4th. Sloughing of the Cellular Tissue.

1st. *Effusion of Serum* is the first phenomenon that occurs when inflammation has become established in the cellular tissue of the pelvis. The necessary result of the effusion of this fluid is a swelling in the part, which may be felt on examination through the vagina or rectum, or even through the abdominal parietes, according to its special seat. This swelling is of greater or less extent according to the intensity of the inflammation, and according to the freedom with which the fluid is allowed to escape along the cellular tissue, and to pass from one loculation or division of pelvic fascia to another. The swelling or tumour produced by the effused serum is from the first firm, dense, and resistant to the feel, and sometimes becomes very hard, particularly when the effusion takes place between two layers of the fascia which are not loose, and mobile, and yielding, but are bound at their margins to some osseous ridge or strong ligamentous band; as when it occurs, for example, in the wall of the pelvis, externally to the margin of the broad ligament of the uterus. In such a situation the swelling comes sometimes to feel hard as a cricket-ball, or a "deal board," as Dr. Doherty has expressed it, and has been, and might easily be, as far as mere hardness is concerned, mistaken for an exostosis of the ilium; and when in the roof of the vagina it sometimes feels as firm to the touch as a scirrhus growth. One other common and very characteristic feature of the tumour is this—it feels as if it were *adhered to* and grew, as it were, from the side of the pelvic bones, whenever the effusion has extended to a sufficient extent laterally, so as to reach the walls of the pelvis. Fibroid tumours of the uterus, ovarian tumours, and others with which the "inflammatory tumour" of pelvic cellulitis are sometimes confounded do not present this symptom. After the effusion has invaded loculation after loculation of the pelvic fascia it soon loses its primary round or oblong form. In examining the swelling day after day you can sometimes find it daily altering its figure, and occasionally you can thus trace its gradual process, as it

creeps from one side of the pelvis to the other, and passes before or behind the neck of the uterus, and at last involves and *fixes* the uterus in its mass. The inflammatory effusion is by no means always limited to the cellular tissue of the lower or true pelvis. Often from the first a large swelling or effusion can be felt in one or other iliac region; and I have seen one or two cases where the tumour was in a great degree central, and as large as the uterus at the fourth month. Occasionally the disease invades the cellular tissue of the upper or large pelvis, and especially the cellular tissue in the right iliac fossa, and around the head of the cæcum, without even stretching downwards into the true pelvis. Again, we see occasionally in practice smaller inflammatory swellings and effusions limited to single loculations of the pelvic cellular tissue situated in the anterior or on the posterior walls of the vagina, and not even passing upwards to the cellular tissue contained between the broad ligaments and lying around the neck of the uterus.

I should wish particularly to have it impressed upon your minds in regard to this disease, that there is no pus in the effusion or tumour at first, and that it does not begin in any case by being an abscess, but that first of all an effusion of serum takes place into the inflamed cellular tissue, and no formation of pus generally occurs till about ten or fourteen days afterwards. In one of the first cases of the disease I ever saw, and when I was only beginning to learn something of its nature and course, I got a lesson in regard to this matter which is very strongly impressed upon my mind. Dr. Andrews, who was then a lecturer on Midwifery in London, was on a visit to Edinburgh at the time, and I offered to show him a case of pelvic cellulitis as an object of interest; for the subject was then new, and not many cases of the disease had been observed. The patient was a young girl, of twelve or thirteen years of age, in whom I had made sure that inflammation had been set up in the broad ligament of the uterus, and caused great swelling and induration of it. This I supposed to be due to an effusion of pus, for we then spoke of and thought of the disease as always "pelvic abscess,"—and about the tenth day from the commencement of the disease, I introduced, in presence of Dr. Andrews, an exploring needle with the view of bringing away the pus and reducing the swelling. But to our astonishment there flowed into the dish held to receive it, not yellow pus, but a transparent fluid so clear and limpid that Dr. Andrews at once whispered to me, "Have you not punctured the bladder?" I knew from the direction of the needle backwards that it was not near the bladder, and after a considerable quantity of this clear fluid had escaped, we soon had evidence that it was not urine, by its rapid coagulation in the cup which contained it. It was serum, such as you see in the stages of many inflammations, and such as you may obtain from the skin after the application of a vesicant; and in the earlier stages of pelvic cellulitis it is this inflammatory serum whose effusion gives rise to the swelling and hardness, and which is the only fluid you will then procure on using an exploring needle. If the inflammation be not now subdued, and the effused serum be not absorbed, it will betimes lead to,

2nd. *The Formation of Pus.*—You may meet with a case of pelvic cellulitis where there is an effusion of serum attended with much pain and distress; yet if the disease proceed no further and resolution of the process be effected, the disease might run its course, and its real nature might be altogether unsuspected, unless you had previously been made aware of the probability of its occurrence. But if the inflammatory process remains unchecked, and goes on to its higher stage of suppuration, the disease is not so likely to be overlooked; and hence most of the descriptions that we have of the disease refer to it only in this more advanced stage. The pus may become developed in any part of the pelvis where inflammation has been set up, and in some cases it is confined to one fascial loculation, while in others it occurs in two or more simultaneously. It does not always remain in the part where first it is formed, but forces its way from one loculation to another, until it reaches a cutaneous or mucous surface through which it may be evacuated. Its progress is often very difficult to trace, and to understand it aright requires an intimate knowledge of the course and connexion of the fascial sheaths of the pelvic organs. Perhaps the most common seat for the development of an abscess is in the cellular tissue of one or other of the broad ligaments of the uterus, and when matter has been formed there it may make

its way towards the roof of the vagina either by passing in front of the neck of the uterus between it and the bladder, or, as is far more frequently the case, by sinking backwards between the cervix uteri and the rectum. In such a case the abscess may open either into the rectum or into the vagina, which are the two most common canals for the evacuation of pelvic abscesses, and fortunately also the two most favourable. But there are two other cavities into which the matter sometimes, but less frequently, finds its way; and as they are not by any means so accessible, the treatment of the case becomes more complicated and difficult. These are the cavities of the bladder, and of the body or cervix of the uterus; and when one and the same abscess opens into both of these organs, as sometimes happens, a form of vesico-uterine fistula results which is not always very amenable to treatment. On the other hand, you will sometimes find the matter burrowing onwards, and finally making an opening for itself in some part of the cutaneous surface of the body. The pus may pass, for example, underneath the pelvic fascia, and escaping from the pelvis along with the femoral vessels, it may come to point somewhere in the groin; or it may pass backwards through the great sacrosciatic notch along with the sciatic nerve, and lead to the formation of an abscess in the hip, as I lately saw in a case which I visited along with Dr. Moir. Again, the matter in some cases sinks downwards, and escapes at some point in the pelvic outlet.

One interesting point which it is of importance to observe and to remember in connexion with the evacuation of pelvic abscesses is the extreme rarity with which they become discharged into the cavity of the peritoneum. When we know that inflammation has been going on around some of the pelvic organs, and has led to the formation of pus beneath the peritoneum, we might be apt to form a very unfavourable prognosis, and to look upon a fatal peritonitis as almost certain to ensue. But experience of such cases assuredly does not warrant us in entertaining such a gloomy view, for this reason, that abscesses forming under the peritoneum very rarely perforate it, and open into its cavity. Why this is so, is not very easy of explanation. Cruveilhier avers that it is because the peritoneum is lined, and protected by a layer of fascia, the existence of which is denied by others. In some cases adhesive peritonitis is set up, and the abscess is prevented from bursting into the peritoneal cavity by the resistance offered to it by the two adherent layers of the membrane. But whatever be the explanation of it, the fact is not the less true, and it is always a hopeful one to be borne in mind—that the peritoneum has a very remarkable power of resistance to the passage of matter, and that, in consequence, pelvic abscesses very rarely terminate by evacuation into its cavity. I shall have to revert again to this point when I come to speak of the artificial evacuation of the pus; and I pass on now to notice another product of inflammation in the cellular tissue of the pelvis, viz.

3rd. *Coagulable Lymph.*—When an effusion of firm, solid coagulable lymph or fibrine takes place into one or more of the fascial loculations in the course of the disease the swelling which results is extremely dense—really as hard as the "deal board" of Dr. Doherty—and many long months usually elapse before it softens, breaks down, and is discharged. I have a patient under my care just now in whom suppuration has set in after an attack of pelvic cellulitis, which came on when she was at the country, so that there is now formed an abscess in the right iliac fossa. But fourteen years ago she had an attack of the disease, which came on after a confinement, and took on the form I now refer to. On that occasion there was an effusion of coagulable lymph into the cellular tissue around the cervix uteri, forming an extremely dense solid tumour, like a hard cancerous growth or deposit in the roof of the vagina. Nearly two years elapsed before this effusion was fully absorbed. When pelvic cellulitis terminates in effusion of coagulable lymph, the swelling is always very long in disappearing.

4th. *Sloughing of the Cellular Tissue* of the pelvis sometimes occurs as a result of inflammation in it. It is produced by the compression of the vessels caused by the effusion of lymph or serum into the surrounding tissue. The parts, deprived of their usual supply of nutritive matter, die, and being separated by a suppurative process from the surrounding textures, they come to lie in the midst of a fetid abscess, and a cure in such a case cannot be accomplished till a free opening is made, and these necrosed masses are evacuated, along with

the pus in which they are imbedded. I have seen cases where very large sloughs thus escaped, or were removed rather by the finger passed through the artificial opening. These cases are always most severe and exhausting in their character, and usually long also in their duration.

Having thus given you a hurried sketch of the history of Pelvic Cellulitis and of its Pathology, I must now tell you something of the symptoms and diagnosis of the disease.

(To be continued.)

ORIGINAL COMMUNICATIONS.

THE EMPLOYMENT OF WATER IN AUSCULTATION.

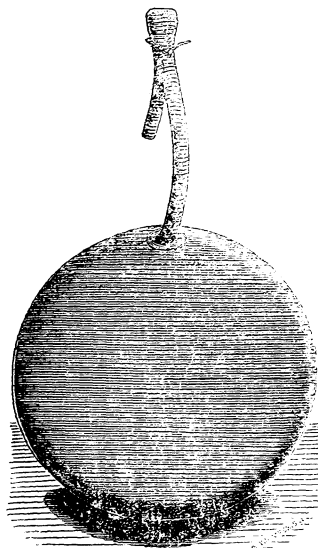

By S. SCOTT ALISON, M.D.

Assistant Physician to the Hospital for Consumption.

(Continued from page 9.)

THE HYDROPHONE.—If we desire to employ water as an agent in auscultation and in aid of hearing-tubes, difficulties at once present themselves. To apply water to the chest is easy enough; but it is not so easy to retain it there in a suitable manner. The application of water may be unpleasant to the patient, and by wetting his clothes may give rise to much annoyance and inconvenience. The idea occurred to me that if I could confine water in some material that would not interfere with its sound-intensifying power, a material advantage would be gained, and we should have a convenient mode of reinforcing hearing-tubes. In the preceding part of this paper it was stated that a thin membrane offers no sensible impediment in the way of water intensifying sound, although thick and non-elastic or non-vibrating bodies did and taking advantage of this fact, I made a waterproof bag of India-rubber to contain water. The India-rubber membrane is so thin as to offer little or no resistance to the undulations of water. The bag is about the size of a large watch, and is sufficient to receive the extremity of an ordinary flexible stethoscope, or to form a medium of connexion between the external ear and a solid sounding body such as the human chest. The thickness of the bag is not above the third of an inch. Nothing is gained by greater thickness, and the advantages of sound having to travel only a short way, and also of only a very little weight pressing upon the sounding body, are secured. The sonorous pulses, so to speak, are readily taken up from the solid body or the chest, and are conveyed through the water, and membrane on either side, and reach the edge of the aperture of the hearing-tube and the contained air, whether the instrument be the flexible stethoscope, the human ear, or any other hearing-tube. This instrument possesses valuable advantages, and I have therefore

ventured to give it a name, that of the Hydrophone. It fits admirably and exactly upon the part of the chest to which it is applied, however uneven and irregular, whether this be a projecting rib or a deeply sunk intercostal space, a broad level surface or a narrow depression, the clavicle or spine of the scapula. By its other side the hydrophone fits as exactly to the aperture of the hearing-tube or to the exterior of the human ear. Every part of the solid body covered by the hydrophone contributes its quota of sound. The fitting of the instrument to the hearing-tube prevents the escape of sound from the contained air to the external atmosphere, and by this means resonance of the contained air, and of the containing

tube is greatly promoted, with the result of a greatly

augmented sound. The edge of the hearing-tube sits so easily, and with so little resistance from the water-bag, or hydrophone, that the vibrations which are communicated to it are readily reciprocated, and find none or little of that resistance so fatal to its vibrations when pressed upon a solid body. (a)

The hydrophone may be employed either in aid of the stethoscope, or as a distinct acoustic instrument by itself. In the case of wooden stethoscopes which are solid, applied to the distal aperture, it is injurious by damping sound; in the case of the hollow wooden stethoscope it is of no material value, for water is an indifferent conductor of sound from a solid body to another solid body, and it may be stated that the hollow wooden stethoscope is more a solid than an air instrument. What it gains as an air instrument from the water, is lost as a solid instrument. In fact, more may be lost in the one way than is gained in the other.

It is in the case of the flexible stethoscope that the hydrophone forms a material aid in auscultation by hearing-tubes. The flexible stethoscope is here meant to signify all stethoscopes into whose construction flexible tubes enter, either forming the whole tube part of the instrument, as in the ordinary flexible stethoscope, or part only, as in Camman's double stethoscope, or my own differential stethoscope. These instruments are essentially air instruments, and I am glad to say that Camman designated his instrument such when he first made it known; for this corresponds with my own investigations. In the case of all these instruments the intensification of sound by the hydrophone is so material, that I have no hesitation in saying that without its employment their resources are by no means fully made available. To have the full benefit of any one of these instruments the hydrophone is essential. Respiratory sounds, healthy and morbid, which are audible with the simple flexible stethoscope, are made more audible when the hydrophone is placed under it. Rhonchi and moist crepitation are strikingly augmented. Vocal resonance, solid and cavernous, dry and moist, are in a marked manner amplified. Pectoriloquy accompanied with much vibration of the chest, is increased in a very striking manner. Murmurs of the heart, usually heard in a mitigated form only by flexible stethoscopes—at least in my experience—are conveyed to the ear so as to produce a very distinct and defined sensation. To sum up, it appears to me that flexible stethoscopes, however ingeniously constructed with twisted wire and other contrivances, are, compared with the simple wooden stethoscope, essentially deficient as sound-conveying instruments, some few sounds excepted; but that the hydrophone greatly counteracts this deficiency and brings them up much more to the rank of Laennec's stethoscope. But the inquiry may be made,—What good purpose can the hydrophone subserve under such circumstances, if it can only bring a second rate instrument nearly up to the position of another? The answer is this,—There are situations and occasions which require the flexible instruments, as is well known, and it is certainly important to render them, defective though they are, as useful acoustic instruments as is possible. It may be possible to place the cup of a flexible tube with a hydrophone under it, where it would be difficult or impossible to employ a wooden stethoscope. In auscultating the sounds of the gravid uterus, or of the fetus in process of birth, a flexible stethoscope with a hydrophone might possibly afford evidence that would under certain circumstances be very important.

Pulsating tumours of the chest, too tender to admit of the pressure of the wooden stethoscope, or even of the naked cup of the flexible stethoscope, or upon which it might be dangerous or hazardous to exercise pressure, are well auscultated by means of the flexible stethoscope, provided either with a flat ear-piece or a tubular ear-piece to enter the meatus, having the hydrophone placed under it and upon the morbid part. The hydrophone takes up sound from every part; however uneven it may be, it forms a soft water cushion, and it serves, at the same time, greatly to reinforce sound procured without it. In practice I have on many

(a) A fact which I have very lately ascertained appears to me well worthy of being here recorded. It bears directly upon the importance of perfect freedom of the cup of flexible stethoscopes. A cup held rather firmly upon a piece of wood upon which a tuning-fork is placed gives a fainter auditory sensation than when held loose, but the auditory sensation is further and very materially reduced, if instead of being held firm, the cup be glued to the piece of wood. Here we have perfect continuity but reduced sound. The explanation is found in the reduced vibration.

occasions, with the aid of the hydrophone, distinctly heard murmurs of the heart, of the existence of which I had been in doubt when simply employing the flexible stethoscope.

I have observed that when the flexible stethoscope is employed with the clothes of the patient intervening, as is unavoidable under some circumstances, as, for instance, when time does not admit of undressing, or when the patient would suffer by exposure to cold, the impression made upon the ear by lung and heart sounds is greatly enfeebled and is very unsatisfactory. This evil attendant upon the employment of the flexible stethoscope, including Camman's double stethoscope, and my own differential stethoscope, is obviated, I may say altogether, by placing the hydrophone under the stethoscope. The reinforcement of the sounds is so great as to be quite surprising, as well as very useful. An examination that would be worthless is by the use of the hydrophone rendered satisfactory. This result is obtained partly by a gentle yet efficient pressure exerted upon the clothes, compressing them into less density by excluding layers of air. But a great portion of the result is due to a more complete closure of the aperture of the instrument, attained by a surface of water covered by thin membrane, than can be secured by one of porous and comparatively uneven cloth, etc.

In the examination of children, the employment of the hydrophone, together with the double or the differential stethoscope, is most satisfactory, and is well deserving of notice here. I believe it to be a very great improvement upon the use of the wooden stethoscope, and well worthy of the adoption of the Profession in dealing with children. The intensity of sound procured is nearly the same as in the case of wooden instruments. The cup of the stethoscope fits perfectly upon the water, which it can seldom do upon the sharply-curved chest of infants, and thus much economising of sound is secured. For the same reasons no irregular pressure is endured. The child suffers no pain, and is spared one great source of restlessness and vociferation. Lastly, the employment of the hydrophone and a flexible stethoscope causes no alarm, as in the case of the wooden instrument, and is very generally the source of much interest and even amusement to the child, who consequently remains in a state of quietude very favourable for the examination of the auscultator. I constantly examine children with the utmost ease and deliberation in this way, whom I should otherwise have to send away after fruitless efforts at auscultation.

The same method of examination, viz. by the hydrophone and the flexible stethoscope, including Camman's double stethoscope and my differential stethoscope, is very valuable in the case of wasted patients. The employment of the wooden stethoscope with such persons is frequently very painful, and is positively cruel. Moreover, as the aperture fits very badly, it is highly unfavourable for the propagation of sound to the ear. Now, the water-pad, or hydrophone, sinks into the hollowed intercostal spaces, and comes into complete contact with the entire circumference of the mouth of the stethoscope, at once collecting more sound, preventing its escape, and obviating the occurrence of painful pressure.

Upon blistered surfaces and parts tender either from internal disease or from external applications, this mode of auscultation is much superior to that by the wooden stethoscope. When an examination by the latter instrument is positively refused, one by the method under consideration is at once permitted as being altogether painless. Many patients, particularly females with tender and wasted chests, have expressed to me their satisfaction with, and surprise at, this painless mode of examination.

A very slight augmentation of sound, in the case of some sounds, is procured by placing the hydrophone on the proximal or aural extremity of the ordinary wooden stethoscope, but it is scarcely available in practice.

The bag of water, or hydrophone as I have ventured to call it, is of service not only in the case of artificial hearing-tubes, but in that of the natural hearing-tube, viz., the ear. Applied to the naked chest it forms a stethoscope not materially inferior to the best wooden stethoscope, length excepted. When the part auscultated is very uneven or much curved, by fitting well, it excels the wooden instrument in an acoustic point of view. By fitting well also upon the external ear of the auscultator, and by closing thoroughly the meatus externus, great acoustic advantages are obtained. The sonorous undulations are freely conveyed to every part of the external ear, the air in the meatus comes in immediate

contact with the instrument without the possibility of any sonorous undulations escaping. The sonorous undulations of the walls of the tube and those of the enclosed air re-act upon each other. The water again reciprocates as a sounding-board, and the general resonance is greatly promoted by the thorough closure of the tube. The closure of the meatus is greatly more complete in the case of the water-bag than can be procured by any ordinary wooden disc. The complete closing of the ear, it may be remarked, is useful chiefly by promoting resonance, and not, as has been erroneously taught by some eminent stethoscopists, by excluding other sounds.

The hydrophone forms a great aid to the external ear when the patient is to be examined with his clothes still upon him. As a general rule, good stethoscopists strip their patients for examination, but it may be sometimes desirable to examine through the clothes, as in probably trivial cases, when there is little time, when the patient suffers from cold, or when the examination is only a supplementary one, or a rough observation will suffice. In such an examination the hydrophone proves of great value: a sound which is very indistinct to the ear placed upon the clothes, becomes full and distinct when the hydrophone is employed. Voice sounds, heart sounds, and rhonchi are greatly improved. Employed in this manner, I am inclined to think the hydrophone is equal, if not superior, to the wooden stethoscope.

The water instrument has this material advantage, that it is very readily moved from one place to another—i.e. from one part of the chest to another. For example, in examining the back, the whole of the surface may be, as it were, run over without once lifting the head, the hydrophone being shifted with the ear upon it from place to place.

In respect of delicacy, the hydrophone is not without some value; for, in the case of females, the interposition of this instrument meets the objection to the immediate contact of the ear of the auscultator with the chest of the patient. When the application of the hydrophone gives annoyance from its coldness, this evil may be readily obviated by placing the instrument in warm water, or by otherwise warming it. Minor advantages of this instrument are its portability and cleanliness.

Other liquids, besides water, tend to intensify sound proceeding from solid bodies, and conveyed to the ear by means of hearing tubes, but none experimented upon have given practically better results. Mercury gives an increase, and the character of the sound is heavy and forcible. Thick glutinous fluids, such as treacle and marmalade, and thick oils, give less increase than water; and much of the fine liquid, vibrating character of the sound when passed through water is lost.

Some solid bodies serve likewise to give a stronger auditory impression when placed upon other solid bodies, when hearing tubes are employed. Layers of paper, such as a pamphlet, layers of gutta serena membrane, and thin slices of India-rubber, lard, and butter, give an increase, but it is much less than is obtained from water. In the case of these solid bodies the augmentation is due to two circumstances: 1st, the exact fitting of the instrument upon them; 2nd, the greater amount of its vibration in their case than in that of more solid and resisting bodies. Dr. Sibson has long employed a stethoscope closed with a thin plate of wood, with the effect of rendering valvular sounds more distinct.

That I may not appear intentionally to ignore anything that has been done by a Professional brother, I deem it right to say, that a water stethoscope was invented some years ago; the name of the inventor I have been unable to discover. I have endeavoured to find some printed details of this instrument, but have failed. Dr. Hamilton Roe and Dr. Markham have informed me that they have seen an instrument so-called. It is said to be a solid tube filled with water, but I cannot conceive it could afford any advantage. If water be made to fill the ordinary wooden stethoscopic tube, I am convinced the addition can only serve to spoil the instrument, for this reason—that water in the interior will interfere with the full vibrations of the wood. It is as an adjunct to hearing-tubes, or employed as the hydrophone, as previously described, that water can prove of service in ordinary auscultation.

Before concluding this communication, I may be permitted to refer to a point which, though not bearing immediately upon the employment of water in auscultation, yet has suggested itself to several Professional friends, viz. the apparent contradiction offered to the sound-propagating properties of water, by the absence or deficiency of respiration and voice

sounds in some examples of liquid in the chest, and of heart sounds in examples of effusion in the pericardium.

I would briefly remark, that though water is a good conductor of sound, second only to wood and other solid bodies, and better in the case of air-tubes as above described, it is yet in many cases opposed to the production of sound, and effectually prevents those movements upon which sound depends. A lung pressed upon by water till it becomes impervious to air is not likely to be the seat of respiration sounds, and if they are not produced inside, they cannot be heard outside. *Ex nihilo nihil fit.*

Besides this the circumstances under which the liquid is situated in respect of the stethoscope or hearing-tube are different. The liquid in the chest is separated from the hearing-tube by the whole thickness of the walls of the cavity; while in the case of the hydrophone and of water employed in my experiments the liquid is brought in immediate, or almost immediate, contact with the aperture of the stethoscope, a condition which, it was stated in the first part of this communication, is essential to the procuring an augmentation of sound from solid bodies by the intervention of water.

Park-street, Grosvenor-square.

REMARKS UPON THE ADMINISTRATION OF CHLOROFORM,

WITH A DESCRIPTION OF A NEW INHALER.

By ARMSTRONG TODD, A.B. M.B. M.R.C.S.L.

It is now nearly twelve years since Professor Simpson, of Edinburgh, described the influence of chloroform as an anæsthetic agent. Although during this long period a very small proportion of those to whom it has been administered have died from its effects, it becomes incumbent upon the Surgeon to investigate the causes of such accidents, however few they may be, and to propose a remedy when such is suggested to his mind.

From a review of the published cases of death from chloroform, I think that the causes of this accident may be divided into two heads; namely, certain physical affections in which experience has shown the administration of chloroform to prove injurious; and, secondly, the want of an instrument so constructed as to admit of the vapour itself being highly and intimately diluted with air, so that the exhibitor can graduate its strength with perfect precision.

On the cases in which chloroform may prove injurious, I wrote a paper in the *Medical Times and Gazette* in 1853 (*vide* No. for April 30, vol. vi. p. 443), the gist of which was, that diseases of the respiratory or of the blood-circulating organs, which retard the free re-oxygenation of the blood, preclude the exhibition of chloroform as an anæsthetic agent. The great danger resulting from the mode of administration seems to me to arise from a too-strong vapour being exhibited before the nerves and muscles of the fauces and larynx have become accustomed to it. It is the function of these nerves and muscles to oppose the passage into the lungs of any vapour likely to poison the blood, and therefore it is that the gradual administration of chloroform is so essential, as when these muscles are thrown suddenly into too great a state of excitement asphyxia is likely to ensue, and death in consequence. Various instruments and methods have been devised for the administration of anæsthetic vapours: some simply permitting the air drawn through a sponge or other reservoir to be inhaled by the lungs. Of these I need not speak, as they have been thoroughly condemned and abandoned. Others have a semblance of admitting of gradual exhibition; but in these there exists a considerable amount of deception.

The gradual administration is not accomplished by the alternate exhibition of the strong vapour and a free inhalation of pure air. A person might just as well be considered to take a weak drink of brandy and water, who takes a wineglass of pure brandy first and a tumblerful of water afterwards; but this is practically the manner in which chloroform is inhaled, when the method so strongly advocated by a few is adopted, namely by placing a piece of lint or a handkerchief upon which the chloroform has been poured, over the mouth and nose—a plan which I believe to be most

dangerous, uncertain, and deceptive. In the inhaler invented by the late Dr. Snow, and in those since constructed, which appear to be mere modifications of his, there exists also great deception as regards the dilution of the vapour with air; the aperture in the mouthpiece which is supposed to admit the air for diluting purposes is too near to the mouth, and consequently even a moderately strong inhalation on the part of the patient draws the chloroform vapour in a dense volume into the lungs, before it has time to mix with the air passing through the opening; this any person will experience if he inhale from a Snow's Inhaler, charged with chloroform, but in the instrument which I have contrived this is impossible when the chloroform is at a proper distance from the mouth, as the stronger the inhalation the more numerous are the jets of air drawn in to mix intimately with and dilute the vapour.

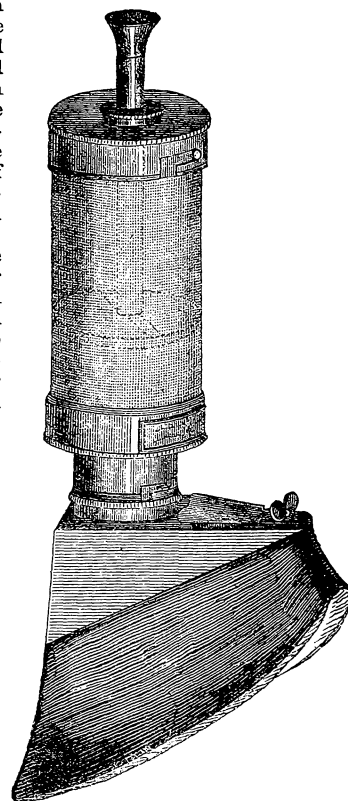

This inhaler consists of three parts, the mouthpiece, the cylinder, and the piston with its rod; these three parts can be separated by means of bayonet joints; the mouthpiece is of the ordinary shape, and has two apertures, one communicating with the cylinder for the admission of vapour, and the other, situated above it, allows of the free discharge of the breath.

The opening between the cylinder and the mouthpiece is provided with a valve, divided into two parts, which open and shut like folding doors, permitting the vapour to be drawn from all parts of the cylinder, and preventing the warm exhalation from coming in contact with the chloroform; the other aperture is fitted with a valve of the usual make, and requires no description. The cylinder is about four inches in length, and about one inch and three-quarters in diameter. It is very minutely perforated throughout, except at the ends, which are solid, so as to form the joints. The piston consists of a narrow flat ring having a small band across it, to the centre of which the rod is attached; a flat sponge for the reception of the chloroform is sewed on to the ring.

The rod is a tube with a funnel at the top, and holes at the bottom, close to the sponge, forming a passage for supplying the chloroform.

I will now explain what are conceived to be the advantages peculiar to this instrument. The most considerable is, that the chloroform can be administered in a gradual and uniform manner; thus the patient can be placed in a state of perfect anæsthesia without his experiencing any unpleasant sensation.

When the piston is raised to its full extent, and the patient inhales, the vapour of the chloroform becomes highly diluted, in consequence of the innumerable jets of air which he simultaneously draws in from the entire surface of the cylinder. When he has become accustomed to the chloroform in this diluted state, the piston may be gradually moved nearer to the mouth, so as to admit air through a portion of the cylinder behind the sponge, which passing through the chloroform causes greater evaporation. At the same time the quantity of pure air admitted between the piston and the mouth for the purpose of diluting the vapour is proportionately lessened, and thus a stronger vapour is administered. In a word, the strength of the vapour to be inhaled can be

increased or diminished at the will of the exhibitor. Since the above woodcut was executed, I have altered the position of the cylinder so as to make it more convenient during operations upon the eye. Mr. Ferguson, of Giltspur-street, has made this inhaler for me.

I have had the pleasure of giving chloroform from this inhaler at several of the Hospitals, with the most satisfactory results. I have never had any struggling on the part of the patient, no suspension of respiration and then sudden inhalations, the result of too strong a vapour being administered before the nerves and muscles, whose natural function is to guard against blood-poisoning vapours, have become weaned to the chloroform. I have not found sickness, although in three cases food had been taken immediately before the operation; in one case at St. Mary's Hospital the patient had eaten his dinner just before he was brought into the operation-room. With this inhaler two drachms of chloroform has always sufficed for ordinary operations, and in a girl of about ten years of age, operated upon for squint by Mr. Streetfield, at the Ophthalmic Hospital, Moorfields, twenty-six minims of chloroform placed her in a perfect state of anæsthesia, and kept her in that state until the operation was completed.

I believe that when the vapour of chloroform is given well diluted, the lungs inhale it more freely, and thus the vapour is brought more extensively in contact with the blood, requiring but little chloroform; the anæsthetic effect therefore passes away more quickly; and thus the patient is placed under more favourable circumstances for recovery from the operation he is obliged to undergo.

16, Old Burlington-street.

CASES OF

PROLAPSUS ANI AND HÆMORRHOIDS TREATED BY THE ÉCRASEUR.

By REDFERN DAVIES, Esq.

Surgeon to the Birmingham Workhouse Infirmary.

W. B. aged 54, by occupation a porter, of pale and exsanguine countenance, but otherwise in good condition, has been the subject of prolapsus ani for the last five years; no cause known for it. He was treated about two years ago by an eminent Surgeon with the nitric acid plan, which only relieved him, however, for a short time; the gut descending again as bad as ever.

Present state.—Upon an examination (shortly after passing his stool), there is seen to be a prolapse of the mucous membrane of the rectum to the extent of about a hen's egg in size. It is composed of three principal lobules, and is of a dark purplish colour, returnable with a little trouble—now facilitated by his having lain in bed for a few days; on introducing the finger into the anus the capacity is found to be increased in size. The vessels going to the prolapsus are much increased in magnitude, some two or three of them presenting to the finger a barrel nearly equal to that of the radial artery. (This fact was particularly pointed out at the time of operation.) He states that the prolapse is usually down; the least exertion, as of walking a few yards, sufficing to cause its descent; that he is in constant pain and misery from it; and that defecation is always attended with the loss of a variable quantity of blood, and at other times an offensive ichorous discharge.

May 18.—The patient well under chloroform (administered by Mr. Jauncey). The mucous membrane of the rectum constituting the prolapse was dragged down by double pronged hooks, and the whole of it removed with the aid of the *écraseur* devised by M. Chassaignac. About a teaspoonful of dark blood was lost, chiefly the contents of the prolapse, which were partially squeezed out. A compress and T bandage applied; to take 2 grains of opii. *Vespere.*—Feels comfortable, and passes flatus. Repeat opium.

20th.—Has gone on well. Bandage removed. An injection of warm water given, which produced a copious evacuation, causing no pain, and accompanied by no blood, save a few dark clots about the size of peas. Continue the opium—gr. ij. daily.

22nd.—Bowels again opened by injection. No pain—no blood; is up and about the ward.

June 25th.—He states that there has been no descent of

bowels since the operation, and that his stools, of natural calibre, pass without any pain, blood, or difficulty. He is daily increasing in strength and flesh.

A. M. aged 53, has been the subject of piles for the last three years, during eighteen months of which time she has been confined to her bed almost continually, walking or even sitting being attended with much pain and discomfort. Defecation is always accompanied with great suffering and a variable loss of blood. Her general appearance is that of a person in a state of great debility from constant hæmorrhages. During the last three months, nitric acid has been freely applied to those piles within the anus, by means of the usual anal speculum. On those occasions its application was both at the time, and subsequently attended with much pain, without being followed by any amelioration of symptoms whatever.

May 25th.—The patient well under chloroform (administered by Mr. Jauncey). Five large hæmorrhoidal clusters were drawn down, and the chain of the *écraseur* having been adjusted at their base, they were removed, with the loss of not more than half-a-teaspoonful of dark blood.

A compress and T bandage. To take gr. ij. opii.

In about half-an-hour after operation, she suddenly got out of bed, intending to make water, and the straining so to do caused her to lose about half-an-ounce of blood and she became faint.

The same treatment as above was adopted.

Save this trifling accident she has progressed very favourably, and is now able to walk about the garden without discomfort, and has neither pain nor loss of blood in passing her stool.

Remarks.—The chief point worthy of notice in these two cases is the demonstration of the great and practical value of the *écraseur* in these affections. In both instances a speedy and safe cure has been effected, and that after the nitric acid plan has failed.

THE LONDON

PRACTICE OF MEDICINE AND SURGERY.

SAMARITAN HOSPITAL.

THREE CASES OF OVARIOTOMY.

(Under the care of Mr. SPENCER WELLS.)

(Continued from page 13.)

Case 2. FIBROUS AND CYSTIC OVARIAN TUMOUR— ASCITES—PLEURAL EFFUSION—OVARIOTOMY— DEATH FORTY HOURS AFTER OPERATION.

[From Notes by Messrs. COOKE and PHILLIPS, House Surgeons.]

E. Q., aged 29, was admitted under Mr. Spencer Wells, March 20, 1858.

History.—She was married seven years ago. Her husband is alive; but she has had no children. First observed a tumour accidentally, low down in the right side in May 1857. She was attended by Mr. Roper, of Shoreditch, and Dr. Oldham saw her in November. The *ballottement* of the tumour was then so distinct that the possibility of pregnancy was suggested. After this the tumour increased, and the abdomen enlarged rapidly from collection of ascitic fluid.

State on admission.—A small, spare, delicate woman, with abdomen larger than a woman at the full period of pregnancy. At the lower part of the abdomen there is a solid tumour freely moveable, not fluctuating. The os uteri does not admit the uterine sound. Motion of the tumour is communicated instantly to the uterus. The catamenia have been regular, but rather excessive.

Progress of the case.—As she was suffering greatly from abdominal distension Mr. Wells tapped her on March 22, and removed thirty pints of turbid serum. The tumour was then found to be rather more to the right than left side, freely moveable, smooth and hard, and measuring about seven inches by six. A certain amount of feverishness and pain followed the tapping, and some pain in the chest, and cough. A sinapism was applied to the chest on the right side. Bitartrate of potass was given three times a-day in drachm doses, and small doses of morphia occasionally. She was afterwards put upon cod-liver oil, and a blister was applied. She left the

Hospital on May 11th, a note being taken at the time, that the respiratory murmur was puerile on the left side, and defective below on the right side, where there was dulness on percussion, and absence of vocal fremitus.

She remained at home until November, 1858, when she was re-admitted. At this time there was, as before, considerable doubt as to the nature of the tumour, and it was felt almost impossible to decide if it were a solid ovarian tumour, or a pedunculated fibrous outgrowth from the fundus of the uterus. In order to assist in determining this question, as the uterine sound would not pass the canal of the cervix uteri, Mr. Wells divided the cervix with Dr. Simpson's hysterotome, and the sound then passed to the extent of six inches. This was thought to be conclusive evidence that the tumour was uterine, especially as the catamenia were abundant, and the tumour and uterus moved together in all directions. Then arose the question whether, as the tumour was evidently killing the woman by keeping up the collection of ascitic fluid, it would be justifiable to remove it. This was settled in the negative, on account of the state of the chest, for, after removing the ascitic fluid a second time, there still remained a troublesome cough and dyspnoea. There were the physical signs of effusion in the right pleural cavity, but a good deal of doubt was expressed by different Physicians who examined her as to the amount of this effusion, and how far dulness depended on the fluid, on consolidated lung covered by a thin layer of fluid, or on displaced liver. Under these circumstances it was decided not to interfere surgically. The patient went home again and took a course of bichloride of mercury and bark, under which, with an occasional return to cod-liver oil, the breathing improved considerably, and she recovered some strength, but the abdominal enlargement considerably increased.

She was admitted for the third time, on June 8, 1859. The tumour had undergone a remarkable change. It was at least double its former size, and though still hard below, was distinctly fluctuating above. It extended from the pelvis to half way between the umbilicus and ensiform cartilage. The uterus only admitted the uterine sound $2\frac{1}{2}$ inches, and the tumour could be moved freely upwards without affecting the position of the uterus; though on pressing it backwards the uterus moved in the same direction. The tumour was surrounded by a large quantity of ascitic fluid. The largest circumference of the abdomen was at about an inch above the umbilicus, where the measurement was 44 inches. The distance from the ensiform cartilage to symphysis pubes was 21 inches, the umbilicus being midway. The general health is far better than before—she is able to walk about, has a good appetite, and sleeps well, but can only sleep when lying on the right side. There is slight cough, but much less than before. The catamenia appeared once last December, but since then she saw nothing till a week ago, when the flow came on, lasted three days, and was in about the usual quantity; she was placed on a liberal diet, with wine and beer, and ten minims of the muriated tincture of iron were given three times a-day. The urine is natural in quantity and appearance, contains no albumen, but some phosphates.

A consultation was held, when the state of the chest became the subject of anxious consideration. The presence of some fluid in the right pleural cavity was evidenced, but the lung played with tolerable freedom, and it was decided that there was nothing in the state of the chest to forbid operation. On the contrary it was hoped that by removing the tumour, the cause of the pleural effusion would also be removed. It was clear that there would never be a more favourable time for operation as the tumour was increasing rapidly. Still the operation was decided on rather in compliance with her earnest wish to obtain relief than by the advice of the Medical staff.

June 17.—Present, the Medical officers, Dr. Heyerdahl, of Christiana, Mr. Roper, Mr. Hood, Mr. Leggatt, Mr. Hulke, etc. Chloroform was administered, and Mr. Wells commenced by making an incision through the integuments over the linea alba from two inches above the umbilicus curving round it down to two inches above the symphysis pubis. When the bleeding had ceased, the peritoneal cavity was opened to the same extent, the tumour being pressed forwards by Dr. Routh, as some twenty or thirty pints of the ascitic fluid were escaping. It became necessary to extend the incision upwards towards the ensiform cartilage, on account of

the large size of the tumour. Some rather extensive adhesions of the omentum, and of three portions of intestine were broken down, and then the tumour was pressed out through the wound. A large cyst at the upper and back part of the tumour gave way at this time, and it is probable that some of the fluid contents passed into the abdominal cavity. The pedicle was very short; or it might almost be said that there was no pedicle, the tumour being closely applied to the right side of the fundus of the uterus; the Fallopian tube much thickened and elongated being closely attached to the walls of the tumour. A clamp was passed, however, between the uterus and the tumour, and the tumour separated by cutting it off, leaving a mushroom-shaped piece of it embraced by the clamp. A vessel in the substance of this piece of the tumour bled a little; but it was stopped by putting on a second clamp and a strong twine ligature, the first clamp not including the whole of the part connecting the tumour with the uterus. The edges of the wound were then brought together by harelip pins, including the whole thickness of the abdominal parietes, and by intermediate superficial sutures of silver wire. Before the wound was finally closed, the ascitic fluid still remaining in the cavity was allowed to run out, and the patient was then lifted to bed.

The tumour consisted of a large lower solid portion, simply fibrous in structure, and of a large upper cyst with fibrinous clots adhering to the cyst wall. When the contents were removed the tumour weighed seven pounds and a-half.

The patient remained very low for about an hour after the operation, but recovered after taking some brandy and water, and vomiting. At 7 p.m., she began to complain of pain in the back and abdomen, which was relieved for a time by an injection of 15 minims of laudanum and 2 ounces of water into the rectum. She could only lie on her right side. The injection was repeated at 8:30; and at 10:30 the report is "Much improved. Skin moist and warm. Pulse 120. She slept for the last two hours without waking, and has not been sick again. No pain." Some clear urine was removed by catheter.

Day after operation.—Slight sickness continued early in the morning, but she feels much better. Pulse 108. Tongue moist. The bed being saturated with ascitic fluid, which had continued to dribble beside the clamp, she was put on to a dry bed, and the portion of tumour projecting beyond the clamp was removed as it was becoming offensive. She complained again at noon of slight abdominal pain, which was again relieved by the opium enema. She slept a good deal during the afternoon. Skin warm and moist. Pulse 100. Breathing rather rapid, and a wish to cough, which was suppressed as it caused pain. She took some champagne and brandy and water in small quantities at intervals during the day, but could not keep anything else on the stomach. The sickness increased towards night, and the pulse became more rapid and feeble.

Second day.—During the night she complained of occasional pain, which she said was relieved by vomiting. Towards the morning the vomiting increased in frequency, and the pulse became more rapid and smaller. Enemata of brandy and water were administered, but she gradually sank and died forty hours after operation.

Examination three Hours after Death.—There were from two to three pints of clear serum in the peritoneal cavity—no blood, nor clots. The peritoneal aspect of the wound was perfectly united, the pins being quite hidden from view by the fold of membrane on either side. There was evidence of peritonitis to a considerable extent in the parietal portion of the membrane, especially on either side of the wound, and over the folds of intestine in apposition. The portion of omentum which had been adherent was also thick, injected, and hard. The peritonitis did not appear to have extended to the more deeply-situated folds of intestine. About a pint of serous fluid had gravitated into the pelvic cavity. The peduncle was completely circumscribed by the ligature. It consisted of the Fallopian tube, and broad and round ligaments. The ligature was tied within half-an-inch of the fundus of the uterus. The opposite ovary was of natural size; but both it and the Fallopian tube appeared to be congested. The uterus appeared to have been the seat of old peritonitis, as there were patches of organised lymph on its posterior surface. In the right pleural cavity there were upwards of six pints of clear serum. The lung was compressed and lying close to the spine, but it was still crepitant,

and floated in water. The substance of the left lung was healthy; but there were extensive adhesions of both parietal and inter-lobular pleura. Nothing unusual in heart or pericardium, except a greater deposit of fat than ordinary near the apex of the heart.

Remarks.—This case and the one recorded last week are instances of a class of cases in which ovariectomy is resorted to as a last resource—as the only thing to be done for a patient otherwise doomed to a speedy death. Large solid tumours, surrounded by extensive ascitic effusion, in broken-down women, are amongst the most unfavourable cases the Surgeon can meet with. Yet in that recorded last week, the success was complete; and in this second case, the pleural effusion, to say the least of it, played an important part in preventing the recovery of the patient. We shall record a third case next week, in which Mr. Wells removed a multilocular cyst from a young woman who is now convalescent. This makes seven cases in which he has performed ovariectomy in the Samaritan Hospital, the results being five recoveries and two deaths,—an amount of success greater than that of many other capital operations.

(To be continued.)

KING'S COLLEGE HOSPITAL.

UN-UNITED FRACTURE OF THE THIGH.—THREE OPERATIONS WITHOUT BENEFIT.—AMPUTATION.

(Under the care of Mr. FERGUSSON.)

A poor fellow who was about two years ago under Chirurgical care in Guy's Hospital, used to remark when at length he was fairly convalescent, that "he thought he knew something of what Surgery was." After a prolonged treatment for diseased knee-joint, he had had resection performed; and as phagedæna attacked the wound, applications of strong nitric acid became necessary. Subsequently amputation through the thigh was required; and on account of profuse secondary hæmorrhage the common femoral had to be tied about ten days later. A man whose thigh Mr. Fergusson amputated a fortnight ago had had an experience but little less severe, while he had been deprived of the consolation which the Guy's patient enjoyed, of knowing that all had been done by a master's hand. The first part of his case had been mismanaged, and from this all his suffering had followed. While at sea, the mate of a ship, a very respectable and intelligent fellow, had the misfortune to break his thigh. Before reaching port (at some distant colony) the bones had reunited, but in such a bad position that the Surgeons whom he now consulted advised him to have it rebroken. Unfortunately, as the event proved, this advice was acted upon, and on the second occasion no attempt at union could be obtained. He returned home to England after a considerable lapse of time, with a false joint in the middle of his thigh, which rendered his limb worse than useless. He was soon afterwards admitted under Mr. Fergusson's care, and a series of operations were performed in the hope of inducing the effusion of bony material. In the first of these, the ends of the bones were scraped and otherwise irritated by means of a tenotomy knife, after the manner so highly lauded by Professor Miller, of Edinburgh. No good result having been obtained, a second operation consisted in the resection of the ends of the bones, or rather of that of the upper fragment; for the saw was not applied to that of the lower one, which was only denuded by the knife. When he was well of this operation, it was again evident that nothing had been gained; and Mr. Fergusson now determined to employ Dieffenbach's plan of ivory pegs. The extremities of the bones were again partially denuded, and long ivory pegs were introduced into both. A string was left attached to each peg, and the lower one loosened and came away about two months after the operation. The upper one still remained fixed, its string having rotted through and been thus lost. An amply sufficient interval having been allowed, and no better result having been obtained from this than from other plans, there seemed no alternative but to relieve the man of a limb which had been a source of so much trouble to him, more especially as the still remaining peg caused much pain and irritation. The poor fellow had, as Mr. Fergusson remarked at the time of

the amputation, borne his sufferings with exemplary patience and fortitude.

The amputation was performed on Saturday, the 18th ult. The mobility at the seat of non-union was so great that Mr. Fergusson was able to amputate by cutting from without inwards in front, and then passing his knife over the upper extremity of the lower fragment, and carrying it downwards and outwards, as done after transfixion. He subsequently dissected round the end of the upper fragment, and sawed away about three inches. On examination of the parts it appeared that what of callus had originally been effused had wholly been re-absorbed, and no evidences whatever of attempted union could be made out. The soft parts about the bones, especially the upper one, were a good deal thickened, as the result of the repeated operations. The ivory peg was found still firmly fixed in the bone, which it had entered to a depth of an inch. It was considerably worm-eaten over the surface which had been exposed to the bone, while on its upper part, which had lain in the soft tissues above the latter, it was not in the least acted upon. The erosions were not nearly so deep as in a peg which we saw Mr. Stanley remove from a similar case about eight years ago.

Mr. Fergusson made some interesting clinical remarks on the case after the amputation; but we have embodied the chief of them in the above narrative. It certainly puts in a strong light the necessity for great care before advising re-fracture of a badly-set bone. Most especially is such advice rash when given to a sailor just landed from a long voyage, in whom the processes of nutrition might well be expected to be not of the best. On its lesson as showing the occasional futility of our most approved methods of treating un-united fracture, even in the most skilful hands, we need not enlarge.

THE ROYAL LONDON OPHTHALMIC HOSPITAL.

THE OPHTHALMOSCOPE IN CASES OF SUSPECTED MALINGERING.

A case came under observation in Mr. Dixon's Clinique the other day, which put in a strong light the usefulness of the ophthalmoscope in cases of alleged imperfect sight without ostensible symptoms. It is well known that in the public services loss of sight is very frequently pretended, in order to obtain a discharge. To ascertain whether the imperfection of sight really existed or not, has many a time taxed to the utmost the ingenuity of the Army or Naval Surgeon. Cases of genuine amaurosis in which no external symptoms can be perceived, but in which, as in Milton's instance,

"The eyes, though free to outward view of blemish or of spot,
Bereft of light, their seeing have forgot,"

are far from infrequent. Immobility or very marked sluggishness of the pupil is, it is true, present in a majority of these. But in their earliest stage this symptom is for the most part wanting. Many a sailor or soldier has, we doubt not, remained long under the suspicion of malingering, in whom retinal apoplexies did really exist, or who was affected with commencing atrophy of the optic tracts. In the discovery of these lesions the ophthalmoscope will henceforth afford most valuable aid.

The man whose case has induced us to make the above remarks is a healthy looking sailor, of about 30, who applied to Mr. Dixon for advice respecting his eyes on Thursday last. He had been in the navy, and had recently, with much difficulty, obtained an order of discharge. He could see large objects, and even perceive large print when placed in certain positions before him, but could not see at all distinctly. There was no trace of congestion about the eyes, and the irides were free and the pupils readily mobile. As far as the most careful inspection could go without instrumental aid, the organs appeared quite normal. Mr. Dixon ordered the use of atropine drops, and as soon as the pupils were well dilated proceeded to an ophthalmoscopic examination. With the greatest ease it was now seen that both retinæ were blotched over with apoplectic extravasations of very various sizes, but many of them abruptly margined. The wonder was, that with such extensive disease the man could see as well as he did.

Apart from the benefit conferred in such a case as the above by the ophthalmoscope in supplying an objective symptom to a case before wholly based upon subjective ones, and therefore liable to much doubt, it furnished also very valuable knowledge as regards treatment. As soon as a Surgeon who, without instrumental aid, had arrived at the conclusion that the man was not shamming, his next impulse under the old system would, no doubt, have been to give a course of mercury, in the hope of arresting the unseen and unknown pathological changes. And such treatment under such circumstances would have been quite justifiable. Knowing, as we now do, however, that the partial amaurosis is not due to chronic inflammation, but to extravasations of blood—a sort of purpura of the retina and choroid—we see the futility of such treatment and the danger which would attend it. The extravasations under consideration often occur in the subjects of albuminuria, and are probably, even when the patient appears healthy, always a sign of impoverished fluids. Under such circumstances mercury is little less than a poison.

LARGE PORTION OF TOBACCO-PIPE LODGED IN THE ORBIT FOR FIVE WEEKS.

A boy of 15 was admitted a fortnight ago at the Ophthalmic Hospital, with a large abscess in the upper lid of the right eye. He said that he had received a blow from a man's fist five weeks before, and the parts had been stiff and painful ever since. The eye was closed by the swelling of the lid, and the skin was on a point of giving way. A puncture was made, and a large quantity, probably half-an-ounce, of mixed blood and pus escaped. All squeezing was carefully abstained from, and the probe was not used, as not a single fact was mentioned to excite a suspicion as to the presence of a foreign body. The lad was directed to apply a poultice to the abscess.

Ten days after the lad attended again, and brought with him the piece of tobacco-pipe which is here delineated. The sketch shows its exact size. On more careful inquiry, it now came out that the blow stated to have been received had been given by a drunken man in the street. The lid bled freely afterwards, but no suspicion as to the entrance of the pipe was entertained, indeed it was not known that the assailant had a pipe in his hand at the time. Soon after the accident the lid had drooped, but no acute inflammation had ensued until a week before the first application at the Hospital. The eye itself had not been touched.

On the occasion of a third visit the swelling of the lid had pretty much subsided, and the lid itself was elevated sufficiently to prove that the levator had not been seriously injured. The motions of the globe were perfect. A probe was passed into the sinus, which still remained, and was more than an inch deep, but no other fragments could be found.

The case is interesting as a remarkable instance of escape from injury on the part of the eye. The pipe had been driven into the middle of the lid, and exactly over the part where there is the least room between the globe and the orbit. The mobility of the eye had, no doubt, secured its safety, which otherwise would have been impossible.

A NEW OPHTHALMOSCOPE.

An ophthalmoscope fitted with adjusting tubes, rests for the patient's head, etc., by which the merest tyro may be enabled to see the deep structures of the eye, is now at use at the Ophthalmic Hospital. It is made by a Berlin optician, at the suggestion of M. Græfe and his assistant. Unlike the one hitherto in use, it is a large cumbersome affair, and requires to be fixed to the table or elsewhere before use. The patient's head being fixed against a rest, the telescope slides of the instrument are adjusted to a proper focus, and this once effected, a dozen observers in succession may look through the eyepiece, and all of them see exactly the same part of the retina without any trouble. It is, indeed, like looking through the tube of a microscope; the object never gets out of focus, and the proper adjustment having been effected by a skilled hand, any one can see the object. The common hand reflector and lens require a long training before they can be effectually used. For purposes of demonstration to a class the new instrument will doubtless soon throw the other out of use, since it prevents the loss of time and risk of annoying the patient's eyes, which a succession of inspections involves. To one well trained, however, so that he can find the optic entrance,

yellow spot, etc. with perfect ease, we doubt whether the new instrument will add much. Its cumbersome size will confine it to the consulting-room or public institution, but at the latter for class purposes it promises to be invaluable. To the artist also it is a great relief, since it leaves the hands at liberty; and to draw from the ophthalmoscope is, with its aid, just as easy as to draw from the microscope. Its cost as at present made is, we believe, about five guineas. No doubt it will soon be to be had in the London shops.

HOSPITAL NOTES.

IS INGUINAL HERNIA REALLY RARE IN FEMALE CHILDREN?

Most of our readers, including many of those who have enjoyed considerable opportunities of observation, will, no doubt, answer the above question with a most confident affirmative. Inguinal hernia is generally considered to be rare in the female sex, but especially so among its younger part. The statistics of hernia operations which we have from time to time published, from the different Hospitals, number upwards of 800 cases, and comprise many cases of inguinal hernia in male infants, but not a single one in which the patient was a girl. We recorded a few weeks ago as a rarity, an example of inguinal hernia in a girl of eight, which had come under notice at Guy's Hospital. Since then, in conversation with Mr. J. A. Kingdon, the able Surgeon to the London Truss Society, we have been assured that the lesion in question is far from being so infrequent as has been supposed. Mr. Kingdon informs us that he has repeatedly seen inguinal hernia in female children, and even in young infants. His sphere of observation at the institution referred to, is, of course, very large indeed. He explains the present erroneous belief of the Profession on this subject, by reference to the fact, that inguinal herniæ in young females are rarely of large size, and never become strangulated, so that they attract but little attention. Still, however, even admitting that this might account for their not being often seen at Hospitals, we should have expected to meet with them oftener in private practice than we do. Mr. Kingdon assures us further, that inguinal hernia in adult females is shown by reference to books of the Truss Society, to be of a far greater comparative frequency as regards the femoral form, than is usually supposed. These books have been regularly kept, and their records since Mr. Kingdon took office, agree in this matter with those of former years, when Mr. Taunton was the Surgeon. Here, again, the same explanation is resorted to. Femoral herniæ are very prone to strangulation, while inguinal in women, are, on the contrary, almost always of insignificant size, and easily reducible.

DIFFERENT MODES OF PERFORMING LITHOTOMY IN THE ENGLISH HOSPITALS.

A large majority of English Surgeons employ the ordinary lateral method of lithotomy on a curved staff. There has been, however, a considerable disposition to endeavour to improve on it of late years. The median plan, so strongly recommended by Mr. Allarton, has been tried by not a few London Surgeons, and amongst provincial ones has found a warm advocate in Mr. Teale, of Leeds. At the London Hospital it was first adopted by Mr. Ward about two years ago, and since then has been employed by his colleagues, Mr. Crichtett and Mr. Gowlland, each in a single instance. All the three patients were children, all recovered well, and in all it was considered that much less than the usual amount of bleeding took place. At Guy's Hospital, Mr. Cock has performed median lithotomy several times, and Mr. Erichsen has done the same at University College Hospital, both Surgeons being, we believe, well satisfied with its results. On all

hands it is considered to be best adapted for children and for small stones. At St. Bartholomew's Mr. Lloyd still continues to operate in all cases by his recto-urethral (median) method, which we described in detail when he first adopted it in 1853. He informs us that he has not yet lost a case after it, and considers it decidedly preferable to the lateral operation. His colleagues, however, without exception, we believe, always employ the latter. At the Metropolitan Free, Mr. Hutchinson always employs his rectangular catheter-staff, and considers that he obtains great advantage from it. The same instrument has been employed at King's College by Mr. Lee, but it is not, as far as we observe, in use at any other Hospitals. In a recent instance in which the calculus was of large size, Mr. Hutchinson injected the bladder with oil instead of water, in the hope of facilitating the dilatation of the parts.

With regard to the median operation as advised by Mr. Allarton, it is universally admitted to be adapted only for small calculi. Now Mr. Lloyd's experience during the last few years has quite proved, that when the anterior commission of the sphincter ani is cut clean through from the perineal wound, there is no danger of the parts not healing. Might it not be well, therefore, to adopt this measure whenever, after the usual median incisions, the stone has been reached and is found too large for removal? Mr. Lloyd's operation gives abundance of room

THE PROVINCIAL PRACTICE OF MEDICINE AND SURGERY.

STATISTICAL ANALYSIS OF SEVENTEEN LITHOTRITY CASES.

THE tabular statement which follows, comprises, as far as we have been able to collect them, all the cases in which lithotripsy was practised between Jan. 1854, and Dec. 1858, in the following hospitals:—

The Royal Berkshire (Reading), the Bradford, the Bristol General, the Canterbury, the Cheltenham General, the Cumberland (Carlisle), the Derby General, the Devon and Exeter, the Dorset County (Dorchester), the Dundee Royal Infirmary, the Durham, the Glasgow Royal, the Gloucester, the Huddersfield, the Hull, the Leeds, the Leicester General, the Liverpool Southern, and Toxteth, the Liverpool Royal, the Newcastle-upon-Tyne, the Nottingham, the Queen's (Birmingham), the Sheffield General, the South Staffordshire (Wolverhampton), the Staffordshire General (Stafford), the West Norfolk and Lynn (Lynn), the Winchester, York County.

TABULAR STATEMENT OF SEVENTEEN LITHOTRITY CASES.

No.	Hospital.	Age.	State of Health at the time.	Operations.	Result.	Remarks.
1	Leeds	60	..	Four sittings.	Recovered.	Discharged well.
2	York	21	Good. Lithic acid. 4 years' stone.	Many sittings.	Cured by lithotomy. Case 63.	Several large fragments passed, and some had to be removed from the urethra by incision just in front of scrotum.
3	Leicester	59	Good. 3 months; stone small.	Single crushing.	Recovered.	A single crushing was performed, and during the three days next following large quantities of debris came away. He left the hospital three months afterwards, as well as ever in his life.
4	Brighton	51	Good. Stone not quite an inch in diameter.	Three crushings during first fortnight, and two others in next three months.	Recovered.	He bore the operations well, and a large quantity of fragments came away.
5	The Queen's, Birmingham	A miner 40 (?)	Phthisical, and out of health. The symptoms had followed an injury to the back.	Four crushings from April 28 to August 11; fragments weighed 5j.	Recovered. (?)	Thought to be well. The urine, which had at first been loaded with pus and phosphates, became quite clear. Lithotomy had been declined on account of the patient's state of health.
6	Hull	55	Good health.	Eight crushings between Sept. 3 and Dec. 1; fragments weighed 5j.	Recovered.	Believed to be well. Discharged with instructions to attend again should the symptoms return.
7	West Norfolk ..	60	Healthy labourer. 1 year; stone small.	Two crushings, with ten days' interval.	Recovered.	No ill symptoms; believed to be well. The stone had at first measured only three-quarters of an inch in the grasp of the lithotrite. The fragments got away weighed four scruples; at the last two soundings no stone was detected.
8	The North Stafford	The first crushing produced severe irritation.	Not known.	We are not in possession of details respecting this case or its result.
9	The Brighton ..	57	In good health.	Five crushings were practised.	Recovered.	The collected fragments weighed more than a drachm and a half.
10	The Glasgow ..	61	..	A single crushing was performed, and was followed by collapse.	Death.	The man died in collapse the day after the first crushing. At the autopsy nothing was discovered to account for the fatal event.
11	The Glasgow ..	23	He had been the subject of stone for many years.	No details.	Recovered.	No details.
12	The Leicester ..	59	In good health; a labourer.	At the first sitting the stone was crushed repeatedly.	Recovered.	After the crushing many fragments were voided, and no ill symptoms ensued. No subsequent sitting was necessary, and when discharged the man was believed to be free from stone. (See Case 16.)
13	The Bradford ..	56	In good health; symptoms of stone for one year.	Two crushings at a few days' interval were practised.	Recovered.	Fragments weighing ninety-six grains were voided.
14	West Norfolk ..	56	In fair health.	Three crushings were performed in the course of about a month.	Recovered.	This man had been treated by lithotripsy, and apparently cured on a former occasion. Three drachms of a phosphatic calculus were got away during the second treatment, and he was discharged apparently quite well.
15	The Norwich ..	48	A farm labourer; in good health. Symptoms for 3 months.	Two crushings were performed at an eight months' interval.	Lithotomy. Not known.	After the second sitting he had orchitis, and all the symptoms of pyæmia followed. Abscesses formed beneath the fascia of one thigh, and in the left leg. Having recovered from the pyæmia he left the Hospital at his own request, and subsequently submitted to lithotomy at his own home. Result not known.
16	The Leicester ..	60	In fair health.	(Under the influence of chloroform.) The stone was twice seized and crushed.	Died. Pyæmia, 2 weeks.	He had been relieved by lithotripsy in 1856 (see Case 12), and again in November, 1857. On the present occasion, symptoms of pyæmia set in on the second day, and death occurred on the fourteenth. Pus was found in several joints; abscesses in both kidneys. The portion of stone remaining in the bladder was not larger than a bean.
17	The Queen's, Birmingham	72	Very feeble; urine ammoniacal and purulent.	Lithotripsy was practised on ten occasions at intervals of a fortnight or three weeks.	Recovered.	Large quantities of phosphatic fragments and detritus were got away, and he recovered.

The list gives us seventeen cases, of which thirteen were believed to be cured by the treatment; two, being unrelieved, submitted to lithotomy, and two died. Of the two in which lithotomy was performed, one resulted in recovery, and the final termination of the other is not known.

All the patients were adults; treatment by lithotripsy appearing to be restricted to such by our provincial Surgeons. The youngest was 21 years of age, and the oldest 72.

In one or two instances (possibly in more), the same patient was the subject of treatment by lithotripsy at different times, and counts in our list as two cases. Thus the man, who, as the subject of case No. 12 was discharged from the Hospital apparently well, ranks as one of the cures, and having been subsequently again admitted, is the subject also of case No. 16, which ended fatally. Here is a source of peculiar difficulty in counting lithotripsy cases. The treatment is by repeated operations, at intervals extending over a considerable period of time, and when the patient is apparently cured, the Surgeon can never feel quite sure that he is rid of his stone. If he is discharged and re-admitted within a month, it would manifestly be unfair to make him count as two cases. (a) In all probability the stone has been formed on a nucleus which was left behind, and is not really a new one. But if the patient has been well, or nearly so, for two years, then he might be classed on re-admittance as a new case. At what period between a month and two years is, then, the line to be drawn? If a man is subjected to lithotomy, has the calculus extracted and recovers, he will be counted as a new case, even if re-admitted for a second operation (as several in our Lithotomy list have actually been) within a few months of the first. The reader will see here a source of much fallacy in statistical attempts to institute comparison between the two methods of dealing with stone. Unless the utmost fairness in counting the lithotrities have been exercised by the writer, he may very easily have doubled his number of recoveries, while, of course, the number of deaths would remain stationary. On this account the advantages of lithotripsy in comparison with lithotomy are probably somewhat less in reality, than they are generally supposed to be by those conversant with the statistics of the matter.

We shall not here make any comparison either between the results of the two operations in Provincial Practice and of the treatment of stone generally in the latter, as compared with that of Metropolitan Hospitals. Both these comparisons will be of great interest, and the facts which we have now accumulated are sufficient to enable us to enter upon them at some length at an early opportunity.

Several of the cases in our list are left in some uncertainty as to the ultimate result. Should any of those who may read it be aware of subsequent relapses or other important facts in the history of any of them, we shall be obliged by their communicating them to us for subsequent use.

Two cases of amputation of two enormous mammae are related by M. Foucart. In one, a girl, 17 years old, the left breast after the operation weighed $8\frac{1}{2}$ kilogrammes, the right breast 9 kilogrammes. In the other case the breasts fell down to the young woman's knees! The left breast weighed 15 kilogrammes, and the right 10 kilogrammes. In both cases the operations were perfectly successful.

CONSUMPTION OF SMOKE IN STOVES AND GRATES.—

We are informed that Dr. Bartlett, of Bedford-row, has patented an invention, by means of which the smoke from new coals passes through a fire made by coals from which all the smoke has been burnt, thereby consuming the smoke and economising the fuel. This invention can be applied to any ordinary grate or furnace, whether marine, locomotive, or stationary. Its application appears, from the drawings of it exhibited, to be very simple, and the fire can be easily replenished. By direction of the Prince Consort, the invention was tested in a stove in the waiting-room of Buckingham Palace, which was worked for twelve consecutive hours against another stove of precisely similar size. The result was that the quantity of coal and cinders consumed was little more than half that used in the stove to which the invention was not applied.

(a) This has, we have no doubt, sometimes been done by those anxious to make out good statistics of their practice.

SATURDAY, JULY 9.

FEMALE DOCTORS.

DURING the late Crimean war, broad shoulders and brawny arms were at a considerable premium,—in fact, were articles of which the supply, in a military direction, was not equal to the demand. Among other expedients suggested to meet the want, it was recommended by the great Solomon of daily journalism, that all those fine, elegantly-habillimented gentlemen, whom we are accustomed to see parading goods of an enticing character to the eyes of our lady population in the various fashionable shops of the Metropolis and other great towns, should become soldiers. These fine youths should instantly drop tape and tape-measures, and grasp the musket, exchanging the dealing with cotton for cannon-ball. Like so many young Parises, they were to leave the ladies and their distaffs, and rush into the turmoil of glorious war—its pomp and circumstance. Not only would their presence in the army be of infinite service to their country, it was argued, but so also would their absence from their usual seats of business. For now the female sex would rush in to fill the vacuum created by the departure, and thus would occupy a true position in the social scale as dealers in linen goods, and other articles of external adornment and utility. Poor females who before were starving would now find happy occupation and homes.

Every one remembers this tale; and so does a writer on *Female Industry* in the last number of the *Edinburgh Review*. He repeats it for the benefit of the world; but he does not seem to have learnt the true application of his own story. We cannot stop, however, to weigh the arguments of the haberdashers male against their female opponents. There may be some truth in the assertion that a great part of the shopman's work is decidedly not feminine employment, in fact, is quite beyond the compass of a woman's strength; and perhaps as much weight in the answer that this part of the work might be done by a few light porters, while the bulk of the *employés* were females. Something also may be based on the present absurd style of female dress—as shopmasters say that crinolined damsels cannot move about as quickly as men, that they take up more room, and are, therefore, longer in serving customers. The other argument, that the chief dealers at these shops—the wives and daughters of the land—have a very insuperable objection to being “attended to” by persons of their own sex, we find on inquiry is utterly unfounded. For some years past the number of females employed in the chief shops has been gradually increasing, and the masters have found and acknowledged that where ladies have the choice of male or female attendants they almost invariably select the latter.

But we are not going to pursue the *Edinburgh Review* writer through all his long article on *Female Industry*. One page of that article, however, tells of “female doctors”—and it is so very weak

a little history, that, taking it as a specimen of the rest, we were not inclined to prosecute our inquiries further. On this point we are certainly capable of forming an opinion, and our opinion is, that the writer demonstrates his incapacity of dealing with the subject he treats about. He clearly cannot either know what the business of a Doctor is, or what the female moral and physical is fitted for and capable of, or he never would have backed up the glaring absurdity of the manufacturing or establishing of that novel hybridity—female Doctorates. Do not the very words, Mrs. Blackwell, Doctor of Medicine, at once raise up before us the image of one of those incongruous combinations which so distressed the clear mind of our friend Flaccus—the serpent of Æsculapius appended to the female face divine?

"Desinit in piscem, mulier formosa superne."

So does not think our Edinburgh Reviewer. He evidently would go in for Bloomerism at a pinch. But let us now see his arguments, and answer them; for it is time that this piece of imported American humbuggery should be exposed.

And first let us express a natural surprise. Why is Dr. Elizabeth Blackwell here amongst us, lecturing on the rights of women to female audiences in England? She has long studied in this, as in her own country; she has filled her mind with good store of Medical knowledge, picked up in the most celebrated hospitals; she has become a highly educated practitioner of Medicine, as must be supposed from the programme. Why then, we ask, is she not, now at this moment, distributing the benefits of all these high acquirements to her go-a-head Yankee female admirers? This is no impertinent question, and we may not unfairly suggest an answer to it. Our Reviewer tells us that some of the Medical Colleges of America now admit female students and make female doctors; and that what has been done there "will soon be done here." This is granted. But he does not tell us where the degree has been granted, and the brass-plate stuck upon the door, whether or not *the business pays*—rather an important part of the question. He omits to tell us whether the Yankee population is as advanced in high discernment as the Universities which make these doctors in petticoats; whether, in fact, our lady cousins beyond the Atlantic really make use of this great opportunity; whether "the moral and emotional considerations involved in this matter" have so taken hold of their minds as to lead them, in their hours of sickness, to rush eagerly and with feelings of thankfulness and gratitude into the arms of a Physician of the Sex. In a word, the Reviewer does not tell us, as he ought to have done, whether the thing really does go down in America. Now, arguing *a priori* from the nature of the case itself, from the kind of duties involved in the *business* of a Doctor, and the constitution of the female mind and body,—and also from the fact of Mrs. Dr. Blackwell's presence amongst us, we venture to suggest that this scheme is a failure in America. Sam Slick has taught us how "a Yankee blade is fixed on a Halifax handle;" and we have had many lessons of late which ought to teach us some little caution in the accepting of American notions and wares. Puccoon has done miracles in America, *argal* it will do miracles here, was Dr. Fell's argument; and this is just the Reviewer's style of argument,—female doctoring is wonderfully good in Yankeeland, therefore it shall flourish in England. Every one remembers the "rise" taken out of us by Dr. Fell, and the laugh it gave our cousins to see us swallow their cast-off articles. Therefore, let us be wise, and rather believe, from the presence of Dr. Fell and Dr. E. Blackwell here among us, that a belief in the principles which they proclaim to suffering humanity does not exist in the country which produces Puccoon and Female Physicians.

The Reviewer says female Doctors don't go-a-head here because of the "proverbial jealousy of the Medical profession;" and, if haply his eye may meet the lines we write, he

will probably put us down among the catalogue of jealous ones. But he is wrong, as well as ignorant of the facts on this point. We will tell him, as proof contradictory of his assertion, that Mrs. Dr. Blackwell received attention of the warmest kind from Physicians both in Edinburgh and London. We ourselves have seen her walking a London Hospital ward, just like any other Professor of the Art of Medicine, and receiving attention and consideration right and left. If she and her Reviewer, in behalf of the female sex, have selected a business inappropriate for female hands and wit, and if the public think so too and won't employ female Doctors, the Reviewer should abuse the ignorance of the public, and not take up that used-up weapon, the accusing of the Medical profession of jealousy, etc. Such a journal should be above claptrops so stale and contrary to fact.

The truth is, that when people talk in this way about the benefits of female doctors in a community they confuse two offices together—the nursing and the doctoring; and they conclude that because a woman makes the best of nurses she must of necessity be a good doctor. Now it has often struck us as strange, that men who thus recommend women for the offices of doctors should stop there. Why do they not claim for women admission into all the honours and duties of the other professions—Law and Divinity? We ask this in all seriousness; and have no hesitation in asserting that the special functions to be discharged by the representatives of the legal and preaching professions would come much more in unison with the "cosmogony" of woman than the functions of physic. We have the proofs on record. Our great Artist, who, we are told, never wronged Nature, has shown us what the wit of woman can do; how well she can wag her tongue, garbed in the toga of a lawyer. Portia, the doctor of law (with the little Nerissa, the lawyer's clerk), was a "Daniel come to judgment," and saved the merchant's life. When all the learned wigs of Venice had in vain essayed to strain the law to cheat the Jew of his vengeance, a woman's wit prevailed. Why, then, may a woman not as well expound the law as practise physic? That she can preach, and with a telling emphasis, the high things of divinity, we need scarcely say; history has its complement of female apostles; and in the last best novel of the day,—in *Adam Bede*—a charming little converter of souls is the *primum mobile*, the heroine of the tale. How a woman can preach, may there be learnt.

In these professions of law and divinity, there is really nothing—comparatively speaking—which need revolt the peculiar sensibilities of the sex; but in the practice of medicine there is something at every turn of it which is repugnant to the feelings and natural mode of actions of women. We do not, however, wish to argue, that because one woman has been a conspicuous warrior, like Joan of Arc, that therefore all women need go to the wars; or, that because there has been a Madame Dacier, all women should become Grecians; or, that every female intellect should be stretching up to the stars and studying parallaxes, because Mrs. Somerville was our countrywoman. Neither need we desire to see women become special pleaders, because of their recognised volubility of speech, or because Portia cut out all the Venetian benchers (a). That women can preach is certain; and certain also that St. Paul had to put them down as preachers even in his time.

Well, then, as one swallow does not make a summer, why should the existence of Mrs. Dr. Blackwell prove the propriety of such a thing as a sect of feminine doctors?

"Why are our bodies soft, and weak, and smooth,
Unapt to toil and trouble in the world;
But that our soft conditions and our hearts,
Should well agree with our external parts?"

Taming of the Shrew.

A much more sensible and correct estimate of the value of

(a) The reader of Shakspeare will tell us that Portia was put up to the clever point by Dr. Bellario, and so, after all, the wit of outwitting the Jew's counsel was the wit of a man.

Mrs. Blackwell as a Doctor and as an author may be found in the *Saturday Review* of May 23.

Telling of Mrs. Dr. Blackwell's Lectures, the witty satirist writes:—

"We do not mean to say that nonsense even as great as this is not talked in England. . . . But an old country like England had the great advantage, that such theorists are much more quickly set down for what they are worth. A Lady-Doctor who invited an audience of London ladies to make their daughters ride because the stars move in space, and because the Spartan women made the Athenians clever, would at once be treated with proper contempt. It is evident that if women are to make Medicine a profession in England, they must do so in a totally different way from that which appears to be fashionable in America. They must be much more modest. We hope they will not lecture at all; and if they do, we hope they will not publish their lectures. They must also entirely avoid the twaddle of sham science, their peculiar office is not to talk about laws of exercise and use, but to win the confidence of females. We are not at all sanguine that women will ever make good doctors—we fear they would want nerve and the gift of silence. But they are entitled to ask that they should be allowed to try the experiment; and of the conditions under which alone the experiment can be tried successfully, they may learn a great deal by noticing the follies and extravagances of Dr. Elizabeth Blackwell."

We recommend these sensible remarks to the consideration of all admirers of feminine doctors, and especially of the *Edinburgh Reviewer*, who writes thus:—"Mrs. E. Blackwell, whose excellent work on the Laws of Health is one of the best which heads this article, led the way; and by the influence of her high character, attainments and success, she has conquered prejudice, and established the enterprise." We shall see.

THE WEEK.

THE literary and political press of Paris appears to have almost unanimously taken up the cudgels in behalf of the pretended curer of cancers. "It is a spectacle," says *L'Union Médicale*, "which is to be witnessed in every age. It would be useless to throw away indignation; and to cover up one's face in despair would be an act of unworthy weakness. It is sad, indeed, to see our science and our art punished for their honesty. We confess the weakness of our art in the cure of cancers, and our confession becomes the force of the charlatan. It is natural that every sick person should desire health; and when we say that we cannot cure him, the instinct of self-preservation revolts within him, and he rushes to the impudent deceivers who cry out, I will cure you. Between these two currents, between science which respects its own dignity, and charlatanism which practises in human credulity, are placed the patient, his family, and his friends; that is to say, opinion, which is something more powerful than science and laws, the vague and indefinite sentiment, which the majority of men adopt without reason, and at last defend with the most implacable of arguments, self-love."

The trial of Dr. Smethurst, for the murder of Miss Banks, began on Thursday. It will probably occupy the court for several days; and become one of the *causes célèbres* of the country. We hear that an attempt will be made on the part of the defence to show that the symptoms and the post-mortem appearances correspond with those of acute dysentery. The sickness and vomiting will also probably be ascribed to the circumstance of the existence of an early stage of pregnancy in the unfortunate woman. From what has already transpired it appears certain that the post-mortem appearances presented by the body, the ulcerated condition of the colon, and the absence of disease in all other parts of the body, are

quite compatible with the fact of the existence of dysentery. In other words, it would be impossible to assert, from the inspection of the body, that the woman did not die from dysentery. It will, therefore, be necessary to prove the murder—if murder there be—by chemical rather than by mere medical evidence.

The recent additions made to St. George's Hospital, have effected two most important objects: the one by securing adequate accommodation for the nurses; the other by providing day-wards for the patients. "The great benefits that must result to a Hospital from having wards without beds, where the more convalescent patients may be during the day, and by which their cure may be expedited, and from thereby lessening the number in the wards where those more seriously ill remain, are palpable and striking; and it is to the credit of St. George's to be the first Hospital in London," adds the *Building News*, "that has set the example of such an arrangement. To enhance the advantages of the day-wards, the roof of the central part of the Hospital will be made flat, so as to serve as an airing-ground for patients. But in order to better adapt this custom of oriental and southern climates to our more variable and inclement skies, it has been advised by the architect to erect a glazed inclosure or conservatory, in which, without injury, the convalescents may at all seasons enjoy the air and light of Heaven." The sanitary condition of the nurses of our Hospitals is matter deserving thorough investigation. The accuracy of the allegations of Miss Nightingale in the work reviewed in another column must be thoroughly investigated.

The insalubrity of Mantua, the Gibraltar of Northern Italy, is well known and acknowledged. Being situated near large lakes, and having several muddy canals in its vicinity, a pestilential atmosphere consequently often prevails in the city and neighbourhood, especially during hot weather. Many facts prove this peculiarity; but one, which becomes most interesting at the present moment, may be mentioned as an illustration. After his defeat at Bassano, the Austrian general, Wormser, retreated to Mantua, in September, 1796, with an army numbering 30,000 men, including 6000 cavalry. When he capitulated to Napoleon, on the 2nd of February, 1797, only 12,000 soldiers could bear arms—all the rest having either died, were labouring under disease, or had become physically disabled from various casualties. Not only were the Hospitals quite full, but even many of the churches had been converted into receptacles for patients. Should Mantua be now besieged by the French, much sickness must inevitably again prevail, more particularly during summer, since, even under ordinary circumstances, this district of Italy is generally unhealthy, fevers and other severe maladies being then always very prevalent.

The Board of Works, the Conservators of the Thames, the Government, and Parliament are talking a great deal about the state of the Thames; but all the talk ends in the application of lime to thirty of the principal sewers which empty themselves into the river. Whether this is of any use, or of no use, or worse than useless, remains to be proved. Chemists differ about it, as may be seen from Dr. Letheby's report, which we give in another page. In the mean time London is being poisoned. The new system of drainage cannot be of any use for the next three or four years, but Boards and Conservators, and Government, and Parliament permit eighteen million gallons of fluid sewage to flow into the Thames every day. Yet this enormous quantity of filth only contains six hundred tons of deposit, or two hundred tons of solid dry material. Surely nothing could be easier than to intercept and carry off

this six thousand tons every day by covered barges. Twenty or thirty barges and four steam tugs would do the work. We have shown before, and so has Mr. Napier, that the plan is simple and practicable. It must be effective. It probably would be self-supporting. Therefore there is not the smallest chance that either Board, or Conservators, or Government will ever think of adopting it unless compelled by Parliament or the Press.

THE FRENCH ARMY IN ITALY.

WE make a few extracts from some interesting letters from the pen of M. Armand, attached to the ambulance of the 4th corps, now publishing in the *Gazette Médicale*.

The battle fought on the Ticino was hotly contested on both sides, and attended with great losses. Everything in our department was organised for acting *cito, citissime*, conformably to the urgency of the circumstances and the injunctions of Inspector Baron Larrey:—"Proceed direct to the bridge, dress the wounded as rapidly as possible, so as to put them in a condition to be evacuated on the Hospitals, and do not lose time in great operations, which may be deferred." Most of the injuries of the head only required simple dressings, for the reason that those which penetrated were usually fatal on the spot. Those of the face were accompanied by the most frightful injury, without affecting the intellectual faculties; the patients, indeed, coming themselves to have their wounds dressed. Wounds of the neck were also usually immediately fatal or comparatively slight. One of the prisoners had received a wound in the mouth with a sabre-bayonet, which glanced off at the side of the jaw, and came out at the lateral and upper part of the neck. There was hardly any loss of blood, and a simple suture at the commissure of the lips, and a bandage were all that were required. Injuries of the upper extremities almost always, whatever their amount, allowed of the wounded repairing soon to the ambulances. Penetrating wounds of the chest and abdomen, usually so fatal, allowed in several instances their victims to survive for some time—usually to die, however, on their road to, or soon after their arrival at, the Hospital. In some cases, however, vigorous reparative power of the economy, and a free use of anti-phlogistic means enabled recovery to take place. Injuries of the lower extremities were numerous, and the fractures were often comminuted. The rule was here, as in other cases, to extract accessible foreign bodies, arrest hæmorrhage, and so to put up the part as to enable the patient to be carried to the Hospital, where the question of amputation would have to be decided. The Military Surgeon is thus compelled to resort to much temporising surgery; and, for our part, we scarce know the case calling for immediate amputation on the field, except when some large projectile has carried away a limb with irremediable laceration. In such a case, even, the amputation need be immediate only when there is, which is rarely the case, dangerous hæmorrhage; for in this case it is preferable to amputate, and tie the vessels regularly, than to apply a temporary ligature to the wounded vessel. When the amount of general stupor is such as to lead to the fear of fatal syncope during the operation, a provisional dressing only should be applied. As we too often saw in the Crimea, whatever we do under these circumstances, if the part injured be the leg, and still more the thigh, we shall rarely save life.

The armies now engaged both use the new fire-arms, the balls of which deviate far less after striking an object than the old spherical balls. We must, therefore, expect a larger proportion of comminuted fractures. Hollow and explosive projectiles being also proportionally more employed, the artillery-fighting has become more murderous. Altogether we have, therefore, to expect a greater proportion of fatal cases among the wounded than heretofore.

After we had disencumbered our ambulances we carefully explored the field of battle, both to remove any wounded that still might have been left, and to direct the interments. There were but few French still wanting succour, but a great number of wounded Austrians had been abandoned. The proof of the precipitancy of the retreat, or rather flight, of the

enemy was the large number of wounded officers they left behind without any provision for their treatment.

While traversing the battle-field of Magenta, the saying which had formerly been current with respect to Russian soldiers, that they must not only be killed but thrown down, was brought to mind. A great number of the killed, in fact, retained in part the attitude they were in on receiving their death-blow. Those who had died from injuries of the head usually fell with their face to the ground, and with complete resolution of the limbs. In those wounded in the heart, death, though rapid, is not so instantaneous that some attitude cannot be taken. A Zouave so struck had fallen on his musket, which he held in the position of a bayonet charge, his energetic face projected forwards, with the menacing attitude of a dead lion. Not far off, as a contrast, lay an Austrian who had died of hæmorrhage; and in his agony he had taken the attitude of supplicating Heaven—his face turned upwards, and his two hands joined with fingers firmly interlaced. A Hungarian hussar killed at the same time as his horse, both being shot through the head, remained in his saddle, carrying the sabre forwards as during a charge. Some of the Austrian officers found among the slain exhibited a distinguished physiognomy, and were dressed with exquisite, almost affected neatness and cleanliness—their features, very different from those of most of their soldiers, seeming to exhibit courage with resignation. Such were some of the impressions made upon us while traversing the field of battle, giving rise to painful emotions, little calculated to dissipate those produced by still more dreadful scenes within the ambulances, the receptacles of suffering of every kind. Physical fatigue is great, indeed, but so also is the moral exhaustion of the surgeon; and great is the error of those who think his heart is hard, and that his impassibility is the result of indifference.

In our ambulances, calmness and resignation distinguished the wounded. To their honour be it said, the soldiers with severe and often fatal wounds, restrained their complaints, and patiently awaited their turns. Groans and murmurs were rarely heard. The stoicism of courage, proud in its wounds, was the general rule. The railway to Milan, which the enemy had not had time to destroy, was of immense service in transporting the wounded to the Hospitals of that city.

(To be continued.)

REVIEWS.

Notes on Hospitals. By FLORENCE NIGHTINGALE. 8vo. pp. 108. London: 1859.

THIS is a remarkable book, and one of sterling worth. It deals with topics in social science, than which few are more important; and it is written by one whose many years' experience in the varied results of Hospital construction and organisation establishes her claims to the attention of the public and the Medical Profession.

No book of a similar kind exists in the English language. The work before us contains material brought together for the first time in a readable and referable form; which, on the one hand, exhibits guiding lights to those who would undertake the construction and organisation of Hospitals for the sick and wounded, and on the other, it furnishes numerous beacons suggestive of difficulties and dangers—beacons, moreover, rendered conspicuous from the fact that they are reared on existing edifices which proclaim their own unfitness for the purposes they were intended to fulfil.

These "Notes on Hospitals" embrace: 1. Papers on the Sanitary Condition of Hospitals, and on the defects in the construction of Hospital Wards, originally read at the Liverpool meeting of the Association for the Promotion of Social Science, in October, 1858; 2. The evidence given by Miss Nightingale before the Royal Commission on the Sanitary State of the Army is here reprinted, with some alterations, from the Report of that Commission; Lastly, Three articles, contributed to the *Builder* newspaper, on the Sites and Construction of Hospitals, complete the volume.

The whole work contains matter of so much public importance, so much material for thought, so intelligently brought before the public, that we would gladly devote some time to a consideration of the topics discussed, did the limited space for reviews permit us to do so.

The first seven lines bring us, for instance, to an important

fact in the outset, namely, the remarkable difference observable in the general aspect of similar cases of disease, especially as to their duration and termination in different Hospitals. An extended experience in Hospitals of various constructions, and with varied administrations, cannot fail to impress the observer that conditions arise out of the construction and administration of the individual Hospital itself, which exercise a powerful effect on the ultimate issue of the cases which pass through the wards. There is, moreover, great difficulty in arriving at correct statistical data, so as to exhibit by comparison the striking differences in the mortality of different Hospitals. As a general rule, Hospital statistics only give the mortality which has taken place in the wards, taking no cognizance of those cases which are discharged in a hopeless condition, and that to a much greater extent from some Hospitals than from others. Again, the sanitary state of an Hospital ought not to be inferred solely from the greater or less mortality. "If," says Miss Nightingale, with a naïveté which not unfrequently enlivens her laconic notes, "if the function of a Hospital were to kill the sick, statistical comparisons of this nature would be admissible. As, however, its proper function is to restore the sick to health as speedily as possible, the elements which really give information as to whether this is done or not are those which show the proportion of sick restored to health, and the average time which has been required for this object."

Miss Nightingale has the rare merit of seldom noticing defects without being prepared to suggest a remedy. Accordingly, in showing that Hospital mortality statistics give little information on the point, because there are elements in existence of which such statistics take no cognizance; she suggests that the Hospitals of London and Paris ought to adopt a uniform plan, so as to give us the required information under the eight following heads:—

1. The numbers admitted for each decennial period of age for each sex per annum.
2. The numbers, similarly arranged, remaining in Hospital at the end of the preceding year.
3. The numbers dead for each sex at each decennial period of age per annum.
4. The numbers discharged cured, similarly arranged per annum.
5. The numbers discharged incurable, similarly arranged per annum.
6. The numbers remaining in Hospital at the end of the current year, similarly arranged.
7. The Diseases remaining, admitted, died, cured, discharged incurable, and remaining, arranged for each sex and each decennial period of age per annum.
8. The duration of cases similarly arranged.

We hope the members of the Statistical Congress, whose next meeting will be held in London, will come to some arrangement to contribute the information we require. So important would be such knowledge, that where records exist it would be worth while to go back for many years to construct such tables, and to continue the same forms hereafter. The duration of cases admitted, the general course and aspect of disease, the origin and spread of fever in an Hospital, the appearance and spread of Hospital gangrene, erysipelas, and pyæmia generally, all afford important criteria whereby to judge of the healthiness or unhealthiness of any Hospital;—nay more, an experienced and observing nurse, daily, if not almost hourly, can see changes come over patients, which changes rarely come under the cognizance of the periodical Medical visitor; but which, when seen, afford another important class of data from which to judge of the general adaptation of the Hospital for the reception and treatment of sick. Restlessness, languor, feverishness, and general *malaise*, anyone in the habit of intelligently watching patients instinctively allies with closeness of wards, defective ventilation, improper structure, bad architectural and administrative arrangements. Thus the sick in Hospital wards come to suffer from something quite other than the disease for which they were admitted.

The specific defects to which such occurrences are mainly attributable, are thus stated in the work before us:—

1. The agglomeration of a large number of sick under the same roof.
2. Deficiency of space.
3. Deficiency of ventilation.
4. Deficiency of light.

These are the four radical defects in Hospital construction; and these topics Miss Nightingale proceeds to consider seriatim in the outset. She then proceeds to examine the causes in the usual ward construction which prevent us from obtaining the conditions essential to the most healthy state of an Hospital. These are considered under the following heads:—

1. Defective means of natural ventilation and warming.
2. Defective height of wards.
3. Excessive width of wards between the opposite windows.
4. Arranging the beds along dead walls.
5. Having more than two rows of beds between the opposite windows.
6. Having windows only on one side, or having a closed corridor connecting the wards.
7. Using absorbent materials for walls and ceilings, and washing floors of Hospitals.
8. Defective condition of waterclosets.
9. Defective ward furniture.
10. Defective accommodation for nursing and discipline.
11. Defective Hospital kitchens.
12. Defective Hospital laundries.
13. Selection of bad sites and bad local climates for Hospitals.
14. Erecting Hospitals in towns.
15. Defects of sewerage.
16. Construction of Hospitals without free circulation of external air.

The varied topics here noticed are fully dealt with in a most able manner; and although we might take exception to some of the conclusions arrived at, and the details of argument which appear to have led Miss Nightingale to adopt certain opinions; yet the aim of the work is so well conceived, and its object so well carried out, and so fully illustrated, that we have the greatest pleasure in recommending it to the favourable notice of the Profession and the public.

With regard to the means of ventilation recommended, for example, we regret that Miss Nightingale entertains an idea so apparently fixed, that nothing can supersede with success the use of doors, windows, and fireplaces as a *natural* system of ventilation. Having already fully discussed this question in previous numbers of this journal, we adhere to what we have before stated on the subject. We believe that doors, windows, and fireplaces have each special functions to perform, apart altogether from the necessity of using them as apertures either for the egress or ingress of air; and we have every reason to believe that the benefits of natural ventilation can be at all times fully secured by an arrangement at once simple and efficient, which does not depend on the existence of doors and windows, and with the efficient action of which the presence of a fire or a fireplace does not in the least interfere. We refer to the system of natural ventilation contrived by McKinnell, of Glasgow, already fully described in the pages of this journal.

We highly value Miss Nightingale's "Notes on Hospitals," both from their intrinsic merit, and for the interest which attaches to the circumstances under which this book has been developed. A highly cultivated mind, early trained by actual practice into a knowledge of all that relates to a proper care of the sick; a most laborious, self-denying, sad, and bitterly-prolonged experience in the Hospitals of the Allied armies during the Crimean campaign; a subsequent extended examination into the construction and administration of many civil and military Hospitals on the Continent and at home; an extended, deep, and painstaking study of the many sanitary questions relating to the important topics which Miss Nightingale has so ably discussed, are circumstances which all contribute to enhance the value of a work whose aim and object at once commends itself to the philanthropic mind. In taking leave of this book, we beg to express the hope that better health may be vouchsafed to Miss Nightingale than she has been hitherto permitted to enjoy; that we may long continue to derive benefit from her extended experience, so that the fund at her disposal may give rise at once to a Model Hospital for the treatment of the sick and wounded, and a Training School for those who are fit, able, and willing to administer to their wants.

PATENT MEDICINES.—In the year ending the 31st March last the duty on patent medicines amounted to £43,090*l*. 14*s*. 1*d*.

PROGRESS OF MEDICAL SCIENCE.

Selections from Foreign Journals.

ON GENERAL ENLARGEMENT OF THE LYMPHATIC GLANDS.

By Professor WUNDERLICH.

IN connexion with the cases of this affection, referred to at pages 373, 479, and 509 of our last volume, we subjoin an interesting account of two others, which have fallen under Professor Wunderlich's notice:—

1. C. L., aged 22, a publican, was admitted into the hospital on August 28. Until February he had always enjoyed good health; but then, apparently as a consequence of cold, the glands of the axillæ swelled to a large size; and a month or two afterwards the cervical and inguinal glands enlarged, and a tumour projected from the upper part of the sternum. He was considerably emaciated; the skin was dry, and partly occupied with prurigo, and there were physical signs of the existence of phthisis. An immense number of enlarged glands, varying in size from a pea to a walnut, were observed in both the cervical regions, the supra-clavicular hollows, and at the nape. Under the right clavicle and at the right nipple, they varied from the size of a bean to a hazel-nut; while in the left axillary region a conglomeration as large as a fetal head existed, soft in some parts, and hard in others, and having portions of the skin adherent. Under the pectoralis and along the arm were several swellings as large as nuts. In the left axilla a lump as large as an apple existed, having several smaller swellings near it. In the inguinal region there were small, hard enlargements. Under the use of iodine, cod-liver-oil, and good diet, his chest symptoms improved for a while, and his weight increased; but the improvement was only temporary, and he died on November 10,—new swellings of glands having of late appeared close to the old ones, while the latter underwent an increase of size, especially such of them as had been touched with iodine. At the autopsy there was found to be enlargement of almost all the lymphatic glands of the surface of the body, varying usually from a nut to an egg in size, and exhibiting in section a bacons (*speckartige*) consistency, a yellowish-red colour, and but little juice. On the sternum there was so hard a mass that during life it was believed to be a displacement of one of the bones. The xiphoid process and attachments of the ribs were surrounded by similar swellings. The whole mediastinum was filled by a similar mass, and the lungs and heart were thrust backwards. The latter organ was normal, and the capacity of the great vessels was not intrenched upon. The lungs exhibited tubercles in various stages. Professor Wunderlich describes the microscopical characters of the glands at great length.

2. A. H., aged 32, maid-servant, had enjoyed good health until August, 1853, when, without obvious cause, the menstruation ceased, and soon after swelling of the cervical glands commenced, which was somewhat reduced by pencilling with iodine. She soon afterwards became pallid and emaciated, and suffered from night-sweats. In May, 1854, pain in the region of the spleen set in, and continued at intervals. In June the glands in both axillæ, the bend of the elbow, and the popliteal space, became enlarged. On her admission, July 27, the emaciation was considerable; enlarged glands of various sizes were observed in the most different parts of the body; there was some pain in the region of the spleen, but no fever until some time after her admission. This again diminished in September, but the enlarged glands increased in number, and the spleen became much larger. On October 2 she died, worn out. At the autopsy the enlarged glands at the surface were found to be very numerous. Large packets occupied the mediastinum, the exterior of the bronchi, and various situations within the cavity of the abdomen. No tubercles were found in the almost bloodless lungs. The spleen was more than doubled in size, arising from the deposit of a yellowish-red mass, which, both to the eye and to the microscope, presented an exact resemblance to the substance of the swollen glands.

The most remarkable circumstance in both of these cases was the enormous enlargement of such great numbers of lymphatic glands.

To such an extent had they increased, that they not only disfigured the form of the body, but from want of space to develop in, became themselves squeezed and flattened into various shapes. The change which the glands had undergone was in nowise of a carcinomatous or of a tuberculous nature; but consisted in an enormous hypertrophy produced with great rapidity, a portion of the nutritive material being deposited in an amorphous condition in the hypertrophied gland. The increase of the peculiar glandular parenchyma was less in the second than in the first case, there being in the former a good deal of coagulated fibrin, and infiltration of incompletely organised matter. The change observed in the spleen is, as far as the author is aware, peculiar and hitherto undescribed. To the unaided eye it most resembled innumerable points of suppuration, save that it was nowhere soft and fluidiform, but, on the contrary, very firm, and almost of cartilaginous hardness. Exactly the same change, but in far less numerous spots, was observed in the liver. The resemblance of this infiltration with the condition of the swollen lymphatic glands, leads to the inference of both being due to a common constitutional affection; and it might be indicated as spleen or liver scrofula. The causes of the affection were discoverable in neither case. The glandular swellings were not secondary to a peripheral affection. They must be regarded as an idiopathic affection; as the expression, in fact, of a constitutional disease. Both patients were excessively pale, which, together with the enlargement of the glands, and in one case the enlarged spleen, gave rise to the suspicion of leucæmia. Repeated microscopic examination of the blood did not confirm this. Little or no pain accompanied the affection. The glands caused inconvenience chiefly from their size; but their pressure being on all sides, they encroached but little on the capacity of the vessels. The heart and lungs were interfered with by the mediastinal glands. There was a slight peripheral oedema. The general condition exhibited extreme anæmia. Fever was only temporarily present, and never assumed the character of hectic. The patients sank under the increasing loss of power.—*Archiv. für Physiol. Heilk. B. xvii. pp. 123—131.*

ON GONORRHEAL RHEUMATISM.

By M. ROLLET.

Notwithstanding what has been written on the subject, this affection is not universally admitted; and Professor Thiry, of Brussels, has recently formally denied its existence—there being, in his opinion, no rheumatism that can be legitimately called gonorrheal, but only instances of arthritis coinciding with gonorrhea, without any relation of cause and effect. M. Rollet, of Lyons, has, however, just published a memoir, in which he maintains the reality and peculiarity of this form of rheumatism. First, the frequency with which gonorrheal subjects become affected with rheumatism is greater than it would be if it were a mere coincidence; and next, there is the repetition of the rheumatism so often met with in a given individual on the occurrence of a new or the revival of an old gonorrhea. While, too, it resembles ordinary rheumatism, it differs from it markedly, not only in its cause, but in the fact of its rarely affecting the muscles, nerves, or viscera, and, above all, the heart. Another remarkable difference consists in its usually being mono-articular, or at least extending to but very few joints—the knee-joint being that which is much the most frequently attacked, and then the ankle, the other joints suffering much seldomer. Then, again, this form of rheumatism is often accompanied by an iritis, the seat of which is preferentially the anterior layer of the iris, and sometimes the serous membrane lining the posterior surface of the cornea, *i. e.* Desmours' membrane, either wholly or in part.

In the absence of pathological examination, it is difficult to say in what the lesions of gonorrheal rheumatism differ from those of ordinary rheumatism; but there can be little doubt that they are not identical. At all events, it is certain that the inflammation becomes much more specially and more strongly fixed in the synovial membrane in this form of rheumatism than in the other, and hence the marked tendency to hydrarthritides which has struck all observers: and when it does not affect the joints, it exhibits a preference for the serous membranes, the sheaths of tendons, accidental bursæ, and Desmours' membrane. Clinically, gonorrheal rheumatism is distinguished by the less acuteness of the inflammatory symptoms, whether general or local, and by a less tendency to suppuration; but, on the other hand, there is a greater

tendency to ankylosis, especially in the small joints, and, in predisposed subjects, to white-swelling. The disease, again, is excessively rare in women, if it is observed in them at all.

Gonorrheal rheumatism seems to depend upon its special causes; for the predisposing and determining causes of common rheumatism have seemed to be without influence in the great majority of cases. The abundance of the discharge appears to be the most general condition upon which its production depends. Prior to the rheumatism the discharge has usually been acute, and sometimes very acute; or having become chronic, has revived again. The duration of the discharge does not seem to exert the same influence. When the rheumatism has become developed, it exerts a revulsive effect upon the discharge, this usually sensibly diminishing, although in a third of the cases it remains stationary. M. Rollet has seen it become more abundant only twice, and suppressed but once. The doctrine of metastasis has no foundation; and in treating the disease we must not seek to reproduce the discharge, as this doctrine would indicate; but, on the contrary, endeavour to arrest it as rapidly as possible, inasmuch as owing to the dependence of the rheumatism upon the urethritis the slightest exacerbation of the latter, might be attended with aggravation of the synovitis. Therefore, copaiba and cubeba, together with injections or cauterisation of the canal, should be resorted to. For the rheumatism itself, blood-letting is useful, local bleeding being, in the majority of cases, preferable. When the acute inflammation has been subdued, or if this never existed, and when articular effusion is the predominant feature, the flying blister is a most effectual means. Emetics and purgatives are valuable remedies, as are also vapour baths, especially towards the end of the malady.—*Bulletin de Thérap.* tome lv. p. 130.

EXCERPTA MINORA.

Laudanum in Weak Vision of the Aged.—Professor Nascar, of Naples, says, that in the case of aged persons whose sight is becoming enfeebled and requires the aid of convex glasses, great advantage is derived, supposing no nervous lesion exists, from painting every evening the eyelids and brow with laudanum, and allowing this to remain on all night.—*Presse Belge*, No. 27.

Chlorate of Potass in Ozæna.—Dr. St. Arnould recommends the following injection to be thrown in or inspired night and morning, after having cleaned out the nares with some injections of tepid water. Chlorate Potass, 32 parts. Boiling water, 1000 parts.—*Ibid.*

OBITUARY.

DR. SAMUEL GRIFFITH.

WE have been within the past week called upon to mourn the loss of the young and distinguished Physician whose name heads this notice. His name appears as a Medical student of King's College, London, at the commencement of the Session of 1843, 1844. And now his professional career commenced in earnest, not by book work, but by practical observation and study. He was diligent in the class and dissecting-rooms, and even more so in the wards of the Hospital. His assiduity in the dissection-rooms secured his being chosen one of the prosectors of anatomy to Prof. Partridge, but so soon as the preliminary subjects of his professional education were mastered, and the more practical ones entered on, he indicated the preference to the study of midwifery and of the diseases of women and children. He became clinical clerk to Dr. Farre, the Professor of Midwifery, who had the charge of the out-patients, women and children, and made the best use of the opportunities of observation his position afforded. He also acted as clinical clerk to Dr. Guy, the Physician for out-patients, and subsequently was in-patient clinical clerk under Dr. Todd, who learnt to esteem his valuable qualities, and who, during his subsequent career, particularly when sickness overtook him, proved himself a most kind and ready friend.

Having become Licentiate of the Apothecaries' Company and Member of the College of Surgeons, he was appointed House Physician to King's College Hospital, and in that capa-

city, besides the arduous duties in the wards, had to lend his aid, whenever called upon, to any less experienced students in the mysteries of obstetrical practice.

He would work indefatigably by day in the wards, and, instead of courting the needed repose and sleep of night, seemed only too happy to find himself spending the midnight hours at the bedside of some poor woman in childbirth. Such exertions were incompatible with even his robust health and vigorous frame; and at this period he doubtless made the first inroads upon a sound constitution. Unwilling as he was, it became necessary for him to remit his labours and to recruit his overtaxed powers by a holiday. At the completion of his Hospital and College career he resided with his father, and became one of the Surgeons to the Royal Maternity Charity, and soon after having taken the M.B. degree at the University of London was elected Physician-Accoucheur to the Farringdon Dispensary.

We cannot in these pages follow his movements in detail, but let us briefly state that he persevered in professional work in an undaunted manner; he lost no opportunity to forward his progress and practice; and his future history, while it is on the one hand an illustration of this assiduity, it is on the other one of the rewards accruing from it. He went to reside in Wellington-street, Southwark, and became Assistant-Accoucheur to Dr. Waller, at St. Thomas's Hospital, and a Licentiate of the College of Physicians. He was chosen Physician to St. Ann's and to the Welsh School, and to the Surrey Dispensary, and Medical Referee of the Star Life Assurance Office. He had likewise been appointed about this period one of the three Physicians of the Royal Maternity Charity, and had the large Central District assigned to him, at the same time receiving from the Committee a valuable testimonial expressive of the very high sense which they entertained of the services which he had previously rendered to that Institution. Beside the active occupation of his public appointments, private practice began to increase; and, in consequence, he found it no longer possible to perform his duties at the Farringdon Dispensary. He therefore resigned this appointment, and had the gratification to receive from the Committee of the Institution a very handsome acknowledgment of his zeal and assiduity in the discharge of the duties of Physician-Accoucheur.

After holding the appointment at St. Thomas's for a year or two, he became coadjutor with Dr. Waller in the midwifery department at St. Thomas's Hospital, and was called upon to deliver lectures on practical midwifery.

His labour was excessive without interruption, and in the winter of 1857 his overtaxed strength began to fail, of which he took little notice; but he was induced to see Dr. Todd, who, finding one of the lungs affected, ordered his immediate desistance from practice, and, after some preliminary treatment, his removal to Torquay. He remained at that town for two months, and returned to London, resumed practice with the same earnestness as before his illness, and with alas! too little caution; for in the ensuing October he was attacked with severe hæmoptysis, which again demanded his withdrawal from practice, and his removal to Devon. In a few months his health became sufficiently recruited to allow his return to London, but still it was as an invalid; the injury the lung had received still showed itself by the frequent short cough, rapid pulse, and respiration. His hopes of the future, however, remained bright; withstanding the rude shocks his private practice had received, it greatly increased, and during the last winter he took the lease of a house in St. Thomas's Street, fitting and furnishing it in anticipation of future years of activity and success. But losing sight of his invalid condition, and acting as if his rude health and powers remained intact as of old, he plunged into practice with his usual ardour. Daily the practice seemed to grow, for he was now the principal consulting Physician in female diseases, and obstetrical cases on the Surrey side of the metropolis; but in April last, having been summoned to a consultation at Greenwich late in the evening, he was exposed to a heavy rain. The fatal malady which lay latent, not extinct in his lungs, was rekindled. Congestion of the lungs followed; he still, however, continued to perform his daily duty, but severe hæmoptysis returned, a few days reduced him to a state of great weakness, and, though every care and treatment were lavished upon him, he made little progress towards amendment. He was able, however, to make the journey to Torquay, animated with the

flattering hope that the climate of that place, which had served him so well before, would again restore him; but, though at first it seemed to renovate his strength, his malady had too far advanced, exhaustion progressed, and unexpectedly, at the moment, issued in death, on the 23rd June last. Thus lived, and thus died, one who was literally respected and loved by all who knew him. A heartiness and genuineness of character, a desire to please and to oblige, a firmness and integrity of purpose, a love of truth, and the possession of sterling, moral, and religious principles, brought him numerous friends, made him beloved in life, and regretted in death.

GENERAL CORRESPONDENCE.

THE TITLE OF DOCTOR.

LETTERS FROM DRs. CHRISTISON, HAWKINS, ETC.

[To the Editor of the Medical Times and Gazette.]

SIR,—The following correspondence relative to the new Licentiates of the Edinburgh College of Physicians, we hope you will consider of sufficient importance to publish. We refrain from adding any comments of our own at present.

In answer to a letter to Professor Christison we received the following reply:—

“Edinburgh, May 19, 1859.

“Gentlemen,—I beg to acknowledge the receipt of your letter of the 19th instant, in which you ask me, as a Professor of the University of Edinburgh, ‘Whether the licence which has been sold for 10*l*. by the College of Physicians of Edinburgh to certain Practitioners of Medicine and Surgery in England, confers on them the legal right of assuming the title of Doctor?’

“In reply I have to inform you the Licence of the College of Physicians does not confer any such right, and that in Scotland the right of assuming the title of Doctor can be acquired by a Medical man only by graduation at a University. I am, your most obedient Servant,

“R. CHRISTISON.”

In answer to a letter to Dr. F. Hawkins, informing him that two gentlemen of this town (Southampton), who had recently obtained the Licence of the Edinburgh College of Physicians were calling themselves on their door-plates and visiting-cards, Doctor, and that his receipt for five shillings (the registration fee for this new qualification) in which they were styled Doctor was being handed about as their highest authority for their assumption of this title; and asking if these gentlemen had really a right to be called Doctor, or if the title had been inserted accidentally? The following was received:—

“Medical Registration Office, June 3, 1859.

“Gentlemen,—In reply to your communication just received, I beg to say that a Licentiate of a College of Physicians, not being a graduate of an University, is not a Doctor of Medicine by legal right, and can only be called Doctor by courtesy. But as this courtesy is customary, and is in fact recommended by long prescription and usage, I have not hitherto seen reason to depart from it except in documents of a strictly formal character, which a mere receipt for money is not.

“I do not designate a licentiate as above described as M.D. in the Register or in any certificated copy of the Register.

“I am, gentlemen,

“Yours faithfully,

“FRANCIS HAWKINS.

“To Drs. Lake, Scott, and Aldridge.”

Graduates to Professor Christison.

“Southampton, June 9th,

“Dear Sir,—We beg to thank you for your communication of the 19th ultimo, respecting the right of Licentiates of the College of Physicians of Edinburgh to call themselves Doctor. Allow us again to trouble you on the matter. Two gentlemen of this town have recently obtained the above licence, and have assumed both on their cards and door-plates the title of Doctor. They defend this assumption by a receipt from Dr. F. Hawkins for the registration fee, which runs thus,—‘Received of Doctor —, &c.’ This document is handed about as an official recognition of their right to the title by the highest authority. We have written to Dr. F.

Hawkins stating the matter, and have received the unsatisfactory answer which is enclosed.

“We must further observe that the public are quite unable to comprehend the distinction between M.D. of Edinburgh and licentiates of the College, who call themselves Doctors of Edinburgh, and that thus an injury is inflicted not only on ourselves, but, indirectly, on the University itself.

“Under these circumstances, we hope you will, both as a Member of the Council and a Professor of the University, give us your advice whether we should take any and what further steps in the matter, and how far the University of Edinburgh itself is inclined or able to protect the rights of its graduates.

We beg to remain

“Your obedient servants,

“GEO. A. K. LAKE,

“GEORGE SCOTT,

“J. H. ALDRIDGE.

“To Professor Christison, M.D.”

Graduates to Dr. F. Hawkins.

“Southampton, June 9, 1859.

“Sir,—We have the honour to acknowledge the receipt of your letter of the 3rd inst.

“We cannot help expressing our surprise that you should not consider your receipt for money as a document of strictly formal character, as it appears to us that all communications relating to Medical qualifications and titles emanating from the Medical Registration Office are necessarily strictly official. That the two gentlemen of this town who have lately bought the Licence of the Royal College of Physicians of Edinburgh consider your receipt as a formal document, is evidenced by the fact of their showing this paper to their friends and acquaintances in proof of their right to assume the title of Doctor. It was because they were using your money receipt as a formal acknowledgment of their legal right to style themselves Doctor, that we took the liberty of addressing you in our last, and we must candidly state that we are by no means satisfied with the ambiguous answer with which you have favoured us. We have always looked upon your office as one formed for the purpose of enabling both the Profession and the public to ascertain without difficulty, and on authority without appeal, the position and title which each member of the Profession is legally right in assuming. If, therefore, you do not deem the Licentiates of the Edinburgh College of Physicians entitled to be formally registered as Doctors, is it right that they should show your money receipt to the world as a legal proof of their right to style themselves such on their door-plates and cards?

“We beg to remain, your obedient servants,

“GEO. A. K. LAKE,

“GEORGE SCOTT,

“JNO. H. ALDRIDGE.

“To Dr. F. Hawkins.”

Dr. F. Hawkins to Graduates.

“Medical Registration Office, 14th June, 1859.

“Dr. Francis Hawkins presents his compliments to the gentlemen who have addressed him from Southampton, and begs to tell them, that although he is sorry to discontinue a courtesy which, under the sanction of no slight authority, he has been accustomed for many years to observe, yet since it seems that in some instances an attempt has been made to take an improper advantage of it, he has directed that in letters and receipts sent from this office, no person shall be addressed as Doctor who has not taken the degree of M.D.”

Professor Christison to Graduates.

“Edinburgh, June 16, 1859.

“Gentlemen,—In answer to your letter of June 9, I beg to inform you that I am not aware of any right, either in law or in courtesy, by which a licentiate of the Edinburgh College of Physicians can call himself Doctor, unless he is also a Graduate of an University. You are well enough aware of a usage in society, not unknown in England, but more common in Scotland, where there is a far larger proportion of Graduates, according to which almost any Medical man is familiarly spoken of and addressed by unprofessional persons as Doctor. You probably also know, that the Medical Act of last year does not prevent a man from calling himself Doctor, provided he do not call himself Doctor of Medicine. Hence any of the new Edinburgh licentiates may, in strict legal phrase, call himself Doctor, because any body whatever may

do the same, even a low quack; but in Scotland there is neither law nor courtesy to support the pretensions of an ungraduated Licentiate of the Edinburgh College of Physicians to be called, or to call himself in any formal way, as for example, on his door-plate, or in announcing himself on going into company, Doctor. The simple reason is, that until a few weeks ago no such anomalous individual was known in Scotland at all as an ungraduated Licentiate of the College of Physicians.

"As to the usage in England, I cannot speak, England must regulate its own courtesies. Whether the General Registrar is correct, or not, in addressing these ungraduated Edinburgh Licentiates as Doctors in his letters, I cannot pretend positively to pronounce, but I think it is an error. The grand general principle of the Medical Act is to concede to every Practitioner of the realm those rights which he has acquired by his qualification, or qualifications, in any division of the realm. If this equitable principle be impassionately acted on, it ought to affect rights by courtesy as well as rights by law. In that case, the said Licentiates have no right to call themselves Doctors in England, having no such right in Scotland.

"I have delayed answering your letter, in the hope that the question might be cleared up by our College of Physicians at a meeting held yesterday. I was unfortunately unable to remain long enough at the meeting to put the question at the only right time for it, but another Fellow informs me that he put the question, and that the President, the head of this very dubious movement, declined to give an answer. I can say, however, that several of the Fellows, who have concurred with him in the movement, assured me some time ago that it was neither their wish nor their intention that ungraduated Licentiates should call themselves Doctors.

"I wish I could accede to your request to be advised by me as to your course of procedure under these circumstances. I do not at present see that the University of Edinburgh can take any steps in the matter. It is not improbable that the question may be mooted at the next meeting of the General Medical Council in August, but I don't know whether that body can solve the difficulty. Meanwhile, every Graduate ought to avoid the concession of the title of Doctor to any but Graduates, unless he be satisfied that ungraduated Licentiates of the London College are already by established courtesy a fair exception.

"I am, gentlemen,

"Your most obedient servant,

"R. CHRISTISON.

"To Drs. Lake, Scott, and Aldridge."

Graduates to Dr. F. Hawkins.

"Southampton, June 28, 1859.

"Sir,—We beg to thank you for your letter, and the order you have given as communicated in your last.

"We have the fullest authority for stating, that in Scotland ungraduated Licentiates are neither in practice, courtesy, or law, styled in a formal way Doctor. Moreover, this being a new thing, your remarks 'that you discontinue a courtesy, which, under the sanction of no slight authority, you have been accustomed for many years to observe,' cannot apply at all.

"There is no secret made in this town, that the sole object of obtaining the Edinburgh licence to practice is, to be styled Doctor; and it seems not a little mortifying, that the first results of the new Medical Act should be such a prostitution of Medical titles.

"We beg to remain,

"Your obedient servants,

"GEORGE A. K. LAKE,

"GEORGE SCOTT,

"To Dr. F. Hawkins."

"JOHN H. ALDRIDGE.

POOR-LAW MEDICAL REFORM ASSOCIATION.

LETTERS FROM MR. ESTCOURT AND MR. GRIFFIN.

[To the Editor of the Medical Times and Gazette.]

SIR,—I shall feel obliged by your giving insertion to the following letters, in order that the Poor-Law Medical Officers may perceive that their cause, though in abeyance for a time,

in consequence of the ministerial changes, has not been forgotten by me,

I am, &c.,

RICHARD GRIFFIN.

12, Royal Terrace, Weymouth, July 1, 1859.

"My Lords and Gentlemen.—I beg most respectfully to call your attention to the complaints of the Poor-Law Medical Officers, with the hope that you will immediately take their case into your serious consideration. A full account of their grievances will be found in the accompanying pamphlets, and in No. 3, (pages 30 and 32,) is the following statement of the Right Honourable T. Sotherton Estcourt, the then President of your honourable Board: "Looking at the question practically, I think we have made some progress. Last May there was almost a doubt as to whether there was a grievance, but now the existence of the grievance is admitted. What I hope to do is, in the course of the present session to prepare a bill (if we can arrive at a solution of the difficulty) and lay it on the table of the House . . . it may then be printed and circulated in the shape of a bill, towards the end of the session, and if it is duly considered during the recess, there will, next session, be no difficulty in carrying it . . . The matter ought not to continue in its present state, and if I continue in office, I shall use the best means in my power to put the question on a better footing, and to make such arrangements as will be satisfactory both to you and to the public." The above quotation will enable your honourable Board to understand the position of the question, whilst in the hands of your predecessors; and as the army and navy Medical departments have been placed upon a more equitable footing, by orders of her Majesty's Government, I earnestly hope that your Medical officers, upwards of 3000 in number, and who have annually the treatment of more than a million and a quarter of the sick poor of England and Wales, will have their grievances removed and their services so required that they may be enabled to do their duty to the poor without feeling that, as is the case in too many instances at present, the paltry pittance accorded to them by the guardians, (a) does not pay the cost of suitable medicines, omitting all consideration of the value of the time and talents devoted to a service which is public, and therefore ought to be remunerated in an equitable manner.

"In the accompanying pamphlets will be found almost all that can be stated on the subject; but should your honourable Board desire to make further enquiries of your medical officers, and will name a day for a deputation to wait upon you, I will call a meeting for that purpose; or, at any time I will attend personally to answer queries, or to assist in preparing measures for a reasonable adjustment of the question.

"Once again, I pray your honourable Board will take up our cause without delay, and carry out the promises made by your honourable predecessors when in office, and that you will carefully re-model a system which is cruel in the extreme to very many of your officers, and I greatly fear is also injurious to the welfare of the sick poor.—I am, &c.

"RICHARD GRIFFIN."

The following letter from the Right Honourable T. Sotherton Estcourt, on quitting the office of President to the Poor-Law Board, explains the intentions of your immediate predecessors:—

"Sir,—I assure you that it is a matter of regret to me that I should be transplanted to a new office, from one where I had gradually become exceedingly interested in the management, and where I was engaged in watching the progress of certain proposed improvements, and hoped to have been permitted to bring them to maturity. Amongst those, I need not tell you the scheme for an alteration of the method of Medical Relief holds a chief place, and I am anxious to lose no time in informing you, and through you, the gentlemen with whom you are associated in this matter, that my successor, Lord March, expresses to me a wish to identify himself with me in the course which I have hitherto followed in this business, that it will not be necessary to re-produce before him the papers and documents, or to re-state the arguments which you have already furnished to me, and that he will, at as early a period as other business will allow, attentively consider the bearings of the question with a view to a practical measure.—I am, &c.

"March 4, 1859.

"R. GRIFFIN, Esq."

"T. SOTHERON ESTCOURT.

(a) 79 Medical Officers receive less than 1s. per patient they attend, and 806, less than 3s. per case, though the duration of illness averages 22 days.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.—JULY 1.

LUNATICS.

Mr. WALPOLE moved for the reappointment of a Select Committee to inquire into the operation of the Acts of Parliament and regulations for the care and treatment of lunatics and their property. The right hon. gentleman said the former committee had proceeded a great way with their inquiries, but had not completed them when Parliament was dissolved. He believed all the members of the late committee but one were members of the present House.

The motion was agreed to.

JULY 4.

PUBLIC HEALTH ACT (1858) CONTINUANCE BILL.

Mr. LOWE moved for leave to bring in a bill to make perpetual the Public Health Act (1858). He observed that the bill of 1858 was proposed at the end of the session, for the purpose of giving to the Privy Council the powers which were contained in the Diseases Prevention Act of 1855, the principal of those powers being the power of inspecting diseased districts. The Act of 1858 would expire on the 1st of August, and not much time therefore was left them to legislate in the matter. He need not say, however, that the proposed measure did not comprehend the compulsory powers of the old Board of Health, but simply gave the Privy Council those powers which had been found necessary and serviceable.

Leave was given, and the bill subsequently brought in and read a first time.

SEWAGE OF THE METROPOLIS.

Mr. JOHN LOCKE asked the First Commissioner of Works whether the Metropolitan Board had commenced the construction of low level sewers, for the purpose of preventing the sewage of the metropolis from passing into the river Thames; or whether, on the contrary, they were merely proceeding with high level sewers, in order to divert the water from brooks and rivulets, and also the rain water, from passing into the river through the present sewers.

Mr. FITZROY said the department with which he was connected had no control whatever over the Board of Works as to the drainage of the metropolis. The whole jurisdiction, superintendence, and construction of those works was vested exclusively in the Board by Act of Parliament. (Hear, hear.) But not to be wanting in courtesy to the hon. gentleman (Mr. Locke), he had put himself in communication with the Chairman of the Board of Works on this subject, and had received from him the following statement, which he would read to the House:—

"The Board have commenced the intercepting scheme by the construction of the high level sewers, in order to divert the flood waters from the lower districts and to facilitate the construction of the low level sewers. They are deeply impressed with the necessity for affording the earliest possible relief to those districts, as well as of diverting the whole of the sewage from the river without any avoidable delay, and have, therefore, directed their attention to providing the engines and machinery for raising the sewage, without which it would be impossible for the low level sewers to perform their office. They have further ordered the immediate preparation of the contract drawings for the northern outfall sewer, into which the contents of the low level sewer will have to be pumped, and have instructed their engineer to lay before them some suggestions for affording immediate relief to the localities referred to pending the execution of the permanent works."

SHARP PRACTICE.—Hospital gangrene, as we are told by his son, is cured without fail by Dr. Pinilla, at the Hospital of St. Jean de Dieu. He covers the gangrenous part with lint, soaked in concentrated sulphuric acid; filling up any hollows with pellets of lint, soaked in the same! "The pain is excessive for two hours, and then gradually diminishes. A hard, dry, adherent surface is left, which separates in eight or ten days, and leaves a healthy-looking wound."

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, June 30, 1859:—

SPODE, JOSIAH, Tasmania.

The following gentlemen also, on the same day, passed their first examination:—

JEAFFRESON, HORACE, Framlingham, Suffolk.

LANCASTER, WILLIAM JAMES, Barnsley, Yorkshire.

MARTIN, TIMOTHY HENRY, Merthyr Tydfil.

MITCHELL, THOMAS CARTER, Kempston, Bedfordshire.

ROYLE, ARNOLD, Southampton.

WALES, JOHN, Downham Market, Norfolk.

WINGATE, ROBERT, Hareby, Spilsby, Lincolnshire.

WINKFIELD, ALFRED, Bedford.

DEATHS.

ANDERSON.—On the 3rd inst. at his residence at Dalston, James Anderson, late of the H.E.I.C.S. aged 68.

MALCOLM.—Dr. J. Malcolm died at Dundee on the 3rd inst. in the 52nd year of his age. Dr. Malcolm's health had for some time past been such as to alarm his friends, and a few weeks ago he went to Bridge of Allan, in order to try the effect of a change of air. He returned, after a fortnight's stay, apparently much recovered. On Friday, however, his symptoms became worse, and he expired on Sunday. His demise will be deeply regretted by a large number of friends, and his loss will be felt by a numerous circle of patients, by whom he was much appreciated in his professional capacity. Before he went to Dundee, Dr. Malcolm was two or three years in the East India Company's service, and made two voyages to China in their employ. He commenced the exercise of his profession in Dundee in 1835; and he has held several appointments of a public character in the town, having been one of the district Surgeons of the Royal Infirmary, to which he was appointed shortly after he commenced practice here, and also of the Parochial Board for a number of years. During the visitation of cholera at Dundee in 1849 and 1853, Dr. Malcolm also exerted himself with great zeal and activity on behalf of the poor sufferers, and received the thanks of several of the public Boards for his conduct on that occasion.

PARKINSON.—On the 18th June at Brussels, William Hancock Parkinson, M.D. F.R.C.S.

THE Poplar Hospital on the 29th June held its third anniversary dinner. About £700 were collected on the occasion.

THE Vice-Chancellor has granted a licence to G. M. Humphry, M.D., of Downing College, Cambridge, to open a hostel for Medical students.

KING'S College Hospital, on the 30th of June, celebrated its twentieth anniversary. Nearly £3,000 were collected on the occasion. Dr. Todd presided.

THE vesicles of clouds and fogs, M. Langlais says, are hollow, containing in their interior, not air, as is generally believed, but watery vapour.

IN a Congregation held in Oxford, on June 30th, the degree of Bachelor of Medicine was conferred upon Augustus Newman, St. John's; John Henry Bridges, Oriel; Edward Robinson, Harvey, Christ Church.

TWO-THIRDS of patients affected with chorea are, according to Dr. Marcé, injured in their moral and intellectual faculties. The symptoms vary between simple change of character and fancies and entire loss of memory, and furious mania.

THE Medico-Chirurgical Academy of Ferrara offers a prize of 200 crowns to the author of the best essay on the subject of "Mental Diseases in Relation to Legal Medicine." The essays in Italian, Latin, or French, to be sent to the Secretary of the Academy before 31st March, 1862.

BARON H. LARREY, before setting out to join the army in Italy, made a gift to the commune of Baudéau of the house in which his illustrious father was born, and also of 500 francs per annum, in order to establish an asylum and school for the children of the commune. Baron Hippolyte Larrey, who now occupies the same post in the French army in Italy as that held by his father, the celebrated Baron Larrey, had a horse killed under him in the thick of the fight at the battle of Solferino.

M. VELPEAU, on placing the 3rd edition of Professor Bennett's work on the "Principles of Medicine" before the Academy of Medicine, proposed that his name should be inscribed on the list of candidates for the title of Foreign Associate.

MEDICAL KNIGHTS.—Last week the following Knights-Commanders, Henry George Roberts, Inspector General of Hospitals, and Dr. John Macandrew, were introduced, and received from the Sovereign the honour of knighthood, and were invested by her Majesty with the insignia of the Military Division of the Second Class of the order of the Bath.

THE conversion of cane-sugar into grape-sugar takes place, according to M. Gelis, when cane-sugar has been subjected for a long time to a high temperature. In such case, two equivalents of cane-sugar are converted into one equivalent of grape-sugar, by displacement of the water which they contain.

FUCUS VESICULOSUS rightly administered, says M. Duchesne-Duprae, will cure a man of his obesity without injuring his health. The *tripe de roche*, also a well-known alga, has cured many a poor fellow of his obesity, who has been forced to subsist upon it in the Arctic Regions. Its use is at length followed by diarrhœa.

In Holland there are three assurance offices for cattle's lives. One company has all its assured cattle vaccinated, as a preservation against contagious pneumonia. Another company inoculates only when the disease has invaded the animals' stalls. The third company does not vaccinate at all. It has been calculated that the first company has lost 6 per 100 of cattle; the second, 11 per cent; and the third, 40 per cent.

THE following advertisement, written in good Spanish, is to be seen every day in the *Diario* of Madrid. The *Espana Medica*, January 27, 1859, which copies it, puts it into Latin, for the sake of decency:—"Pallidis puellis quarum valetudo nondum florescit, laborante menstro, illis quæ frustrâ hactenus cupiebant gravidas fieri, hic est remedium quod ab extera regione secum perducit juvenis viator. Facile, simplex, naturale, datur secretè."—*L'Union Méd.*

M. DEVILLE asserts that the number of dead births in Paris is greatly on the increase. "From all this," he says, "it follows mathematically" (according to statistical mathematics it should be understood,) "that the number of children born dead in Paris, has constantly increased during the last thirty years. In 1829, the number was 5 per 100; in 1839, 9 per cent.; and in 1849, 11 per cent. The causes he attributes to the too frequent use of ergot of rye in parturition, and to criminal abortion."

UNIVERSITY COLLEGE, LONDON.—The Council at a session held on Saturday last, after passing a vote of thanks to Viscount Palmerston, for his kindness in acting as president at the distribution of prizes that day, for the eloquent and impressive address which he delivered, and for the ability and courtesy with which he discharged the duties of the office, appointed Dr. Harley to the Professorship of Medical Jurisprudence, about to be resigned by Dr. Carpenter, in consequence of his being required to devote the whole of his time to the registrarship of the University of London.

A curious case of an ovarian cyst opening spontaneously five times during three years into the digestive tube, is related by Dr. Isnard. The cyst must have opened both into the stomach and the colon, as the liquid was evacuated by vomiting as well as by stool. The patient appears to have been radically cured by the injection of 50 grammes of tincture of iodine into the cyst. The iodine caused no symptom of poisoning, although the presence of the metal could be traced

in the urine ten days after the operation. Two years after the operation the patient was in perfect health; the remains of the tumour being scarcely perceptible in the side.

WOUNDED IN ITALY.—The following from a Vienna correspondent must be taken *cum grano*:—"From an Austrian Surgeon, now a prisoner of the French, we hear of the most atrocious deeds perpetrated by the Zouaves on entering a hospital at Magenta. Directly the battle was over, the infuriated savages rushed into the streets, stormed the building, although a white flag was waving from the roof, and actually shot a number of the wounded men lying in their beds. They bayoneted another Austrian Surgeon, of the name of Dr. Forst, who was at the time bandaging the arm of a Frenchman. Those of the wounded who were able to stand up fled to the cellars of the house, whence they were rescued by the timely interference of the officers. Afterwards, the French Surgeon, Dr. Mery, endeavoured to compensate, by the greatest attention, for the ill-treatment these poor invalids had suffered at the hands of his countrymen."

BIRTHS AND DEATHS AT ST. PETERSBURG. These were as follows in 1853—7:

In	Births	Deaths.
1853	16,668 ..	21,607
1854	16,649 ..	22,482
1855	17,252 ..	26,724
1856	17,549 ..	24,680
1857	18,110 ..	20,708
	86,228	116,201

From this quinquennial statement it results that there is an annual average of 23,200 deaths—18,314 males, and 4886 females. In the year 1857 an exact enumeration exhibited 494,656 inhabitants, viz. 348,336 males, and 176,320 females. In the course of the five years the births exceeded the deaths by 25,078.

THE QUEEN'S UNIVERSITY IN IRELAND.—The report of the Examiners on the June Examinations in Medicine was received by the Senate of the Queen's University, at a meeting held on the 27th ult. The following gentlemen have passed for the degree of M.D.:—1. Mr. Thos. Alexander O'Flaherty (recommended); 2. Mr. Robert Edward Heath (recommended); 3. Mr. Arthur P. Holmes; 4. Mr. Michael J. Rahilly. And the following gentlemen have passed the first Medical Examination of the Queen's University:—1. Mr. Matthias O'Keefe, M.A. (recommended); 2. Mr. Henry Whittaker (recommended); 3. Mr. Albert A. Gore; 4. Mr. William Jones. The degrees will be conferred at a public meeting of the University, to be held on the 14th of October.

PRIZE QUESTIONS.—The Société de Médecine de Toulouse offers a prize of 300 francs for the best essay on the "Value of Caustics in the Treatment of Cancer." The essay, legibly written in French or Latin, to be sent to the Secretary of the Society before the 1st January, 1860. The subject of the prize for 1861 is, "The Influence of Cultivation upon Plants employed in Medicine." The Medico-Chirurgical Society of Bologna offers a prize of 100 Roman crowns for the best essay (written in Italian, French, or Latin, and sent in prior to the 31st May, 1861) upon the following subject, "Suckling Considered in Relation to the Diseases of the Nurse and the Infant." The Medico-Chirurgical Academy of Ferrara offers a prize of 200 Roman crowns for the best essay on "Mental Diseases in their Relations to Legal Medicine." The essays in French, Italian, or Latin, to be forwarded by 31st March, 1862.

ROYAL SOCIETY.—The following gentlemen were elected Fellows of this Society on Thursday, June 9th:—Samuel Husbands Beckles, Esq., Barrister, St. Leonards-on-Sea; Frederick Crace Calvert, Esq., F.C.S., Professional Chemist, Oxford-road, Manchester; Henry J. Carter, Esq., S.E. Ind. Service, Bombay; Douglas Galton, Esq., Captain R.E., Chester-street, London; William Bird Herapath, M.D., Lond., F.R.S.E., F.C.S., Bristol; George Murray Humphry, Esq. M.D., F.R.C.S., Surgeon, Cambridge; Thomas Sterry Hunt, Esq., A.M., Professional Chemist, Montreal, Canada; John Dennis Macdonald, Esq., Assistant-Surgeon, R.N.; William Odling, Esq., M.B. Lond., Sec. C.S., Chemist, Kennington-road, London; Robert Paterson, Esq., M.R.I.A., Belfast; John Penn, Esq., C.E., Lewisham; Sir Robert Schomburgk, Her Britannic Majesty's Consul, Bangkok;

Thomas Watson, M.D., F.R.C.P., Henrietta-street, Cavendish-square; Robert Woodroff, Esq., Superintendent Great Seal Patent Office, Fulwood College, St. John's-Wood; William Yolland, Esq., Lieut.-Col. R.E., F.R.A.S., Inspector of Railways under Board of Trade, Westbourne-park, Hyde-park.

VITAL STATISTICS.—During thirteen years of observation Dr. Marc D'Espine, a most persevering statistician, has collected 16,856 cases of death from 80 different kinds of diseases. Each of the principal causes of death has been studied separately by him; the deaths caused thereby are divided into twelve periods of ages, and at the same time separated according to sex, and habitation in town or country. A second table gives a distribution of deaths through the twelve months of the year, with a similar division of sex and habitation. Finally, in the text, which accompanies each of these instructive tables, the author gives particular details, which he has not introduced into the tables, such as the powerful influences of fortune. This work of comparison and criticism, which must have cost him great labour and researches, is very precious. It enables us to discover the meaning of the differences met with here and there; and it strongly confirms the conclusions offered in England, Belgium, and Geneva. The author, moreover, is a true statistician; he well knows the importance of a critical examination of statistical documents, and he very seldom omits subjecting his own materials to it. Here is one example of his method:—**Cancer.**—The cancerous diathesis has a decided preference for the upper classes of society. This cruel disease, which between 40 and 70 carries off more than one-ninth of the population, is a cause of death *twice* as frequent in the upper classes than among the general population; (of 1000 deaths 111 are of the upper class, from this cause, and 52 only of the general) and as regards sex, 57 women to 32 men. In cancer of the stomach, 52 deaths in the upper classes to 23 general; of the breast, 14 to 5; of the uterus, 13 to 8.

MIDDLESEX HOSPITAL.—The annual distribution of prizes to the students in the School of Medicine took place yesterday at the hospital, the Dean of Canterbury presided. The prizes were distributed as follows: Prizes and certificates of honour awarded in the summer session of 1858—*Materia Medica*, Mr. T. Jones; *midwifery*, Mr. W. Brend; *Medical jurisprudence* (general examination), Mr. W. Brend, (weekly examination), Mr. S. C. Noble; *practical chemistry*, Mr. W. Brend and S. C. Noble, equal; *botany*, Mr. R. Wrixon. Prizes and certificates of honour awarded to first year's students, winter session, 1858-9—Mr. T. W. Spurgin, first prize; Mr. J. Harper, second prize certificates of honour; *Physiology and general anatomy*, Messrs. T. W. Spurgin, J. Harper, C. Sutton, R. P. Tyley; *anatomy*, Messrs. T. W. Spurgin, J. Harper, R. P. Tyley, C. Sutton. Prizes and certificates of honour awarded to second year's students, winter session, 1858-9—Mr. T. Jones, first prize; Mr. B. Wrixon, second prize. Certificates of honour—*Medicine*, Messrs. T. Jones, R. Wrixon, and R. Williams; *physiology and general anatomy*, Messrs. T. Jones, R. Wrixon, T. Dane, R. Williams; *surgery*, Messrs. T. Jones, R. Wrixon, R. Williams, T. Dane; *physiology and general anatomy*, Messrs. T. Jones, R. Wrixon, T. Dane, R. Williams; *anatomy*, Messrs. T. Jones, R. Wrixon, R. Williams, T. Dane. Prizes to third year students—*clinical prize in Medicine*. Mr. P. R. Cresswell, Melbourne, Australia. Governor's prize for the best reports in *clinical Medicine and Surgery*, Mr. W. Brend; *honorary certificates of general good conduct and diligence*, Messrs. G. Birch, W. Brend, C. Bromley, J. P. Cresswell, P. R. Cresswell, H. McNeile Gould, R. J. M'Morris, S. Meredith, S. C. Noble, S. H. Perkins, A. J. Roberts, W. Sawkins, H. Tayler, A. Tyler, F. S. Worthington. Dr. Stewart and the Dean of Canterbury having briefly addressed the assembly, the proceedings concluded.

THE EDINBURGH COLLEGE OF PHYSICIANS.—We extract the following passage from a very able address by Dr. Radclyffe Hall, at the annual meeting of the South-Western Branch of the British Medical Association:—"During the past year, the Medical Act has formally become law, and no sooner had it so become than the two Colleges of Physicians of London and Edinburgh respectively altered their constitution. But how differently! Whilst the London College, with just and proper liberality, offers to admit within its

ranks all respectable physicians who do not already belong to it, the Edinburgh College proffers to make any medical practitioner who is not a physician at all into a physician on his paying to it ten pounds sterling! In virtue of the new Act, he can afterwards demand to be registered as a duly qualified physician, having passed no physician's examination whatever! It is to be hoped that the self-respect of our profession will deter its members from supporting this sale of medical indulgences; and so, by rendering the English traffic less lucrative than was anticipated, lead its promoters to remember the purpose for which their college was established. A distinction in letters, whether in medicine, law, or divinity, which may be obtained by merely paying down a few pounds, is worth—precisely what it costs; it proves pecuniary ability; nothing more. The initials of physician by purchase would correctly intimate the estimation in which the possessor of such a distinction will be held by every one but himself. Meanwhile, the profession as a class suffers. There is a want of more of recognized authority in our profession; and not of less. And although colleges may have but little power to create this, they are not, as in this instance, without the power to lessen that which exists. I feel personally that faith is not kept with those who formerly considered it creditable to be connected with the Edinburgh College of Physicians; and that in bare justice, every fellow ought to have a vote in deciding whether or not so radical a degradation of his college should take place. Surely there is great defect in the constitution of the Medical Council of Great Britain, if it cannot interfere to prevent so grave an abuse of vested authority as this."

STATE OF THE THAMES.—The following important remarks are from a report by Dr. Letheby:—"Last year I commenced my inquiries on the 20th June, when the river was exceedingly offensive, and from that time until the 17th of July it was regularly examined. The phenomena which have been observed on the two occasions are very similar. There was first a continuance of dry weather, then a succession of heavy rain storms. These occurred at the time of low tide, so that the filthy matters which were scoured out of the stagnant sewers were carried upwards in the course of the river. The previous drought had filled the bed of the river with sea or brackish water, and then a rise of temperature to about 60 degrees set the whole of the corrupt matters in a state of active fermentation. The amount of ammoniacal vapour and of fetid gases evolved from the water has been enormous: as much as 15 cubic inches of the latter, and a grain and a half of the former have been obtained from a gallon of the water by simply heating it; and although the fetid gases do not contain a trace of sulphuretted hydrogen, they contain a putrid organic vapour which is in the highest degree offensive. Last year the soluble organic matter in the Thames at high tide ranged from 10 to 20 grains per gallon, and the insoluble from half a grain to six grains. This year it has been from four to ten and a-half grains, and the insoluble from half a grain to six grains. The condition of the river has not, therefore, reached its maximum of impurity. It was in its worst state in the week ending on the 21st of May, when the soluble organic matters amounted to rather more than seven grains per gallon. From that time until the week ending on the 11th June, it gradually improved, and the proportion of organic matter fell to about four grains per gallon; but since then it has been steadily increasing, and last week it contained more organic matter than I have yet seen in it. I expect, therefore, that when the final conditions of putrefaction are present, the river will again put on its most offensive appearance. Nor will the lime which is now being cast into the sewers at their outfalls have the least protective influence; for though it may check putrefaction for a time by fixing the organic matter in an insoluble form, yet the precipitate which is thus produced will be cast upon the fore-shores of the river, and will then pass into a state of active decomposition. At Leicester and Tottenham, where the process of defæcation is carried on, the greatest care is taken to prevent the organic precipitate from flowing into the rivers; because experience has proved that lime will not prevent putrefaction, but will merely hinder it, and that the precipitate which it forms with the organic matter of sewage, will soon take on the most disgusting kind of decomposition. I have had bottles blown to pieces by the force of the fetid gases set free during the putrefaction of the lime slush contained in them; and

those who have visited Leicester or Tottenham, must have seen how soon the lime precipitate takes on the putrefactive change if it is not speedily separated from the clear liquor and dried. That which is required therefore in the treatment of the Thames at the present time, is some more radical remedy than the mere palliative influence of lime, which may perhaps in the end be worse than useless. I make this remark, because I know that a false confidence will be placed in the protective power of lime, and because it has been stated that the remedy is of my suggesting. If lime is used at all as a defecating agent, it must be employed in the proportion of not less than twelve grains per gallon of sewage; and the precipitate must be carefully separated from the clear liquid; if not, it will assuredly ferment in a short time, and then there will have been a useless addition of many tons of insoluble matter to the already turbid river."

VIRCHOW'S CELLULAR PATHOLOGY.—The object of Dr. Virchow's work on Cellular Pathology is to establish a new foundation for the creation of a Philosophical Medicine. Dr. Virchow desires to put an end to all the one-sided theories now in vogue—to the theories of the humorist and the solidist; to the crasis, exudation, and blastema, iatro-chemical, and iatro-mechanical, theories. In the place of all these partial stories, he proposes a knowledge of the fine organic processes of cell-life as the only foundation of a rational doctrine of disease. The cell-theory, and its relation to practical medicine, however, is not altogether a novelty; but according to Virchow it has as yet only reached a certain stage of progress. What has been heretofore done, stands as a mere forerunner to his cellular pathology,—just as ideas stand to deeds, and imagination to investigation. The foundation upon which he fixes his deductions are actual histological facts, which he places before his disciples in the shape of microscopical preparations and drawings. It will be said by some that there is nothing new in the founding of pathology on histology. And on this score reference may be made to the last edition of Rokitsky's work, which is filled with numerous microscopic representations of diseased structures. It may be indeed asserted that Rokitsky even laid the axe to the root of his earlier, and somewhat humoral style of pathology. He has rejected the doctrine of Crases. In his third edition Rokitsky says:—"The origin and increase of cells and nuclei take place, either immediately out of a blastema, as free cells and nuclei, or in mother-cells and mother-nuclei, endogenously;" and he adds, "the extra-cellular origin of these elements out of a free blastema cannot be doubted, in my opinion, at the present moment." Virchow, on the other hand, utterly rejects the theory of the origin of free cells in a structureless blastema; just as elsewhere men reject the theory of equivocal generation. He asserts, that only out of ready-formed structures arise cells; and that out of old cells there is a continual growth and development of new cells, *omnis cellula ab cellula*. He substitutes a cell-growth theory for the blastema theory. He does not consider exudation as a peculiar product of the capillary vessels, containing plastic and other constituents; but he regards it as an ordinary transudation mixed with the products formed in the diseased structures outside the vessels, among which products may be mentioned fibrin, pus, mucus, etc. Hence, then, according to Virchow, the inflammatory process does not take place in the capillaries, but in the elements of the tissues themselves—in the cells which through an increased activity attract the blood to them, and become thickened and swollen. In this manner, by cell-growth and by attraction of the juices, likewise arise all other new formations; the homogeneous, as well as the heterologous and malignant, so also new areola, or bony tissues, pus, tubercle, sarcoma, and cancer, the disease of plants, etc. The history of heterologous forms is this. In a particular place, or at a particular time, or in a particular degree, there arises a growth which is not proper to the part. Some other structure normal in some parts of the body is substituted at the part for the structure normal to it, forming what Virchow calls a pathological substitution of tissues. The malignancy of heterologous growths consists in this: that the tissue affected is, by its vascularity, disposed to form a fluid, which is injurious to the structures around. The dyscrasie, also, can only arise through the propagation by means of the blood, of the products of certain existing local affections. For example, the so-called phlogistic or fibrinous crasis

depends originally upon a local production of fibrin in an inflamed tissue—fibrin being always a local product, and never arising in the blood. Many other blood-diseases, also, depend upon diseased states of the spleen and lymphatic glands—those being glands in which white and red blood corpuscles arise. The disease which authors call pyæmia consists partly of thrombosis and emboli, partly of ichon-hæmia, of leucocythemia; the substance which forms the obstruction in phlebitis not being pus, but a purulent-like detritus. Pus arises only out of tissues. Life and disease, in fact, cannot be explained by physical or chemical actions, but are the developments and processes of organised elements. —*Schmidt's Jahrb.*

VITAL STATISTICS OF BERLIN IN 1858.—The enumeration in 1858 gave 463,000 inhabitants, exclusively of the soldiery, and during the year there occurred 16,577 births and 12,730 deaths, so that there was a birth to every 27·9 inhabitants, and a death to every 36·3, and 121 births for every 100 deaths. Of the 16,577 births, 8491 (51·2 per cent.) were males and 8086 (or 48·8 per cent.) females. The illegitimate children amounted to 2506, or 15·1 per cent. of all the births, so that there was 1 illegitimate birth in 6·6 of the general births, and to 5·6 of the legitimate. Of the illegitimate children, 49·8 per cent. were males and 50·2 per cent. females. There were 873 (500 males, 373 females) children born dead. There were 218, or 8·6 per cent., of the illegitimate children born dead. The marriages amounted to 4701, or 1 marriage to 98 inhabitants. Of the 12,730 deaths, 6823 (53 per cent.) occurred in males, and 5907 (47 per cent.) in females. Including the dead born, there were 4865 (38 per cent.) who died during their first year, 6401 (52 per cent.) during the first five years, 6803 (53 per cent.) under 15 years of age, and 1743 (13 per cent.) who reached more than 60 years of age. Among the causes of death were debility from birth in 505, debility from old age in 530, suicide in 119, accidents in 142, childbirth in 100, variola in 396, gastric liver in 439, inflammation of the brain in 676, delirium tremens in 52, croup in 136, inflammation of the thoracic organs in 830, inflammation of the abdominal organs in 176, erysipelas in 35, scarlatina in 38, measles in 16, pertussis in 27, trismus and locked-jaw in 106 (96 being children in their first year), unspecified forms of convulsions in 679 (540 of these being young infants), diarrhoea and cholera in 687 (651 being infants), scrofula in 119, dropsy in 355, diabetes in 2, organic cerebral affections in 144, diseases of the spinal cord in 21, phthisis in 1675, marasmus and debility in 1017, chronic bronchitis in 122, organic heart disease in 184, organic disease of the stomach in 60, softening of the stomach in 82, jaundice and organic disease of the liver in 115, Bright's disease in 49, abdominal phthisis and other organic diseases of the abdomen in 683, and sudden deaths from apoplexy, etc. in 758. At the beginning of 1858 the Charité Hospital contained 962 patients, and in the course of the year 9967 others were admitted, and 9919 discharged, 1116 of these last (giving a mortality of 10 per cent.) being dead. In the whole of the charitable establishments of Berlin there were 1642 patients on the 1st of January, and 15,041 were admitted, and 15,053 either died or were discharged during the year. The entire mortality amounted to 1844, which, upon the entire number of 16,683 patients, furnishes a mortality of 11 per cent. The number of days of treatment were 655,667, *i. e.* upon an average, 39 days for each patient.

HARVEIAN ORATION.—Dr. Aldis commenced the oration to which we alluded last week by adverting to the honour due to those Medical men who by their learning and experience had contributed so many and great things to the improvement of their profession. The following topics were then eloquently alluded to in the course of the oration:—The origin of Medicine; the impossibility of learning it properly by experience alone, and the necessity of studying both ancient and modern writers: but in the words of Harvey, men were not to swear such fealty to their mistress, Antiquity, as openly and in sight of all, to deny and desert their friend, Truth. Medical history, unfortunately, afforded many examples of despisers of the mighty dead and of eminent living authorities. Paracelsus burnt the writings of Galen and Avicenne before his pupils, and proclaimed himself king of Medicine. Hahnemann much resembled Paracelsus, for he despised the inspection of dead bodies, and preferred the homeopathic doctrine to pathology. Hahne-

mann's doctrine, that numerous chronic diseases originated in the itch, was neither new, safe, nor true. Dr. C. G. Zieger had many years before promulgated the same idea in a dissertation published at Leipsic in 1758, without boasting, as the other did, that he was engaged twelve years in the discovery. False theories, however, with scientific pretensions, had flourished through many ages. Hence arose Homœopathy, Kinesipathy, table-turning, and various despicable "isms" of the present day. But happily for the poor, at least, such lies could not exist in the schools of Harvey, Baillie, and Hunter. The low consideration of Medicine at the time of Linacre, and its improvement with the aid of Henry VIII. and Cardinal Wolsey were then mentioned. Linacre, the founder of the College, and Dean Colet, the founder of St. Paul's School, of grateful memory to the orator, were among the first to restore ancient learning to this island. The election of Dr. Watson as representative of the College in the new Medical Council, and the labours of Dr. Francis Hawkins, when Registrar, were noticed. Some remarks upon Harvey's grand discovery of the circulation of the blood, appropriately introduced the consideration of those epidemic diseases which contaminate the vital fluid and destroy numbers of the population. Hence the vast importance of sanitary science, not as a speciality, but as a component part of Medicine. This subject having been prominently brought forward, it was thought that the exertions of the Earl of Shaftesbury in improving the dwellings of the poor, and of the Earl of Carlisle in obtaining the enactment of the Nuisances Removal and Diseases Prevention Acts, deserved the highest praise, as well as those of Drs. Southwood Smith and Arnott, who were the pioneers of preventive Medicine. A well-merited and feeling eulogium was then passed upon the late Drs. Bright, Hughes, and John Scott, with a notice of their lives and writings. Reference was made to the attention bestowed by the Fellows on the formation of a new Charter, by which it was intended to embrace within the College those Physicians who had been too long dispersed and disunited. The College was now to be congratulated upon its increasing numbers and extending usefulness. A statue had been erected to the honour of Jenner, under the auspices of Prince Albert, and if he deserved this tribute, surely Harvey, the fountain and origin of modern Medical science, merited similar reverence. Even the remains of Harvey are now lying in a neglected state; but an inquiry had been commenced by the College with the view of removing such a scandal. The statue formerly placed by the Fellows in the College had unhappily perished by fire, and had never been replaced. The orator concluded by expressing a strong wish that a grateful country would either erect another statue or at least found a Scholarship in honour of the learning and genius of Harvey.

MEDICAL EDUCATION AT ROME.—"For one Baroni who honours Rome, Italy, and Europe, we of course must expect to meet many asses. But these are more numerous at Rome than at Paris or Bologna, because the priests there interfere with Medical instruction. I shall not soon forget the mad laugh which escaped me, when on entering the amphitheatre of the Santo Spirito Hospital, I saw a body exposed for the study of the young men covered with a vine leaf. In that land of modesty, when the chaste vine entwines itself into all the branches of the science, a Doctor in Surgery employed in an Hospital confessed to me, that he had never seen the breast of a woman. 'We have,' he said, 'two doctorates to pass, theoretical and practical. Between the first and the second examinations, we practise in the Hospitals as you see. But the priests, who interfere with our studies, do not permit a Doctor to assist at an accouchement before passing his second examination, and obtaining the practising licence. They are afraid of scandalising us. We exercise our hands by delivering images of dolls. In six months I shall have passed through all my studies, I shall have practised Surgery, and I may then deliver as many women as I please, without ever having seen a single case!'"—*About. La Question Romaine.*

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29.907 in.
Mean temperature	63.5
Highest point of thermometer	81.3
Lowest point of thermometer	48.5
Mean dew-point temperature	55.8
General direction of wind	Variable.
Whole amount of rain in the week	1.24
Amount of horizontal movement of air in the week	345 miles.

TO CORRESPONDENTS.

M. A. B.—Duncan-terrace, Islington.

Dr. Young's paper will be acceptable.

Mr. Corner.—The case shall not be neglected.

Fresco, M.D. had better make the inquiry of the Secretary of the College.

Mr. Lewis.—We know of no such claim to reward as that put forward by Mr. Lewis.

Dr. Fox's paper on Cyanosis has been received, and shall be inserted in an early number.

Her Majesty's Levée.—Among the names of Medical men presented at the last Levée, we should have inserted Dr. W. W. Mott, of the Bengal Army, by Lord Kinsale.

A Member of the Royal College of Physicians.—We never insert any communication unless authenticated by the real name of the writer, for our own guidance, not necessarily for publication.

Dr. Spencer speaks highly of the use of a saturated solution of Camboge in water as an injection into the rectum when ascariæ are present. He uses "ten or a dozen syringesful" of this solution.

Habot.—Dr. Guy, from modified data, gives the following as the average, duration of life in different classes:—Aristocracy, 67.31; gentry, 70.22; learned professions, 68.36; trade, 68.74; officers of army and navy, 67.59; literature, &c., 67.55; fine arts, 65.96. Married, 66.77; single 62.06—difference 471.

Mr. Craig complains that in a review of his book "On the Influence of Varieties of Electric Tension as the Remote causes of Epidemic and other Diseases," we have incorrectly represented his views. On a careful comparison of Mr. Craig's work with our review, and with his recent letter, we find no reason to retract our sentiments as to his facts or his theory. We are entirely at variance with Mr. Craig as to

the identity of nervous power and electricity; and we deny that "digestion and respiration can be maintained and produced" by that agent.

Dr. S.—Small-pox is (as is well known) on the increase in this country. The following is the list of the deaths from this source in the City of London during the few past years:—In 1855, the number of deaths from it was 58; in 1856, the number was 33; in 1857, it was but 14; and in 1858, it was only 6; but during the last nine months of the present year it has risen to 19. It appears that not only the non-vaccinated, but that the vaccinated also, are attacked frequently by the disease, although in a very modified form. This seems to point out the necessity for re-vaccination.

A Surgeon and Apothecary.—Ulcerations consecutive to the operation of tracheotomy are always prevented, M. Bretonneau asserts, by the use of his tube, which is composed of three pieces—a half canula above, and a half below, containing between them an internal cylindrical canula. The advantages obtained by its use (as related by M. Trousseau) are these:—1. Once introduced the two half canulas are kept apart and immovable by the perfect canula within them. 2. The internal canula may be always readily removed and cleansed. 3. The trachea is never injured; and the operator can, if he desire it, readily pass a curved instrument with a sponge, etc., into the larynx, etc., without removing the canulæ.

THE CYCLOPÆDIA OF ANATOMY, ETC.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you do me the favour, in your next number, to correct an error which may injure me, contained in your review of Todd's Cyclopædia of Anatomy and Physiology (see the 19th page of your last number) by which I am placed at the head of a list of those contributors to that work who have been removed by death during its progress.

I am, &c., B. G. BABINGTON,

Author of the Article on Morbid Conditions of the Blood.

31, George-street, Hanover-square, W. July 4, 1859.

[It was *Mr.* not *Dr.* Babington, alluded to in the Review as one of the deceased contributors. We publish Dr. Babington's note at his request, although the highly respected writer is too well known to be still among us to render it probable that any of our readers can have been led into error.—*Ed.*]

GERMAN OPHTHALMIC HOSPITAL.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Relative to an article which appeared in the last number of your paper, perhaps you will have the goodness to give publicity to the following few remarks.

Germany can boast of more eye hospitals, private as well as public, than all the rest of Europe together. The Ophthalmic Hospital of Vienna is one of the largest public Institutions of the kind in the world, and has been hitherto justly considered as the parent source of ophthalmological science, having produced more eminent Ophthalmic Surgeons (*viz.* Beer,äger, Gulz, von Graefe, Arlt, Rosus, Liffenbach, Mackenzie, Quadri, and a host of others), than any other school in the world. When I name it the parent source of Ophthalmic medical science, I do so from the well known fact that the greater number of the heads of this speciality in our own country, as well as in France, Russia, Italy, Sweden, and Denmark, have studied there.

Almost all the smaller towns in Germany can boast of an eye hospital, be it small or large; Halle has one, Munich two, Leipzig one, and Prague, Pesth, Breslau, Königsberg, Bonn, Heidelberg, and other towns too numerous to mention have each their eye hospital and school for the study of diseases of the eye.

I am, &c., JAMES G. HILDIGE.

Dublin, July 4.

AIR-PESSARIES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Only one of the misrepresentations which Dr. Keiller's last letter contains appears worthy to be confuted. After having fully determined on the treatment to be adopted, I chanced to be passing Dr. Keiller's house on the night in question, and considering that such cases as the one I have recorded are of infrequent occurrence, and believing Dr. Keiller to be interested in the possible applications of the caoutchouc air-bags, I called on him with the simple desire that he should have an opportunity of witnessing their application in what I then believed to be an untried capacity. Influenced by the same considerations, I related the successful issue of the case to Dr. Keiller, whom I happened to meet on the afternoon of the following day—not, as he incorrectly states, during Hospital visit, but at a private operation, at which I had been engaged to assist, and at which he chanced to be present. How my well-meant courtesy has been repaid your readers are aware.

Dr. Keiller publishes an irrelevant letter from his "friend," who appears to know just as little about the matter as might have been expected.

But it cannot escape your readers that Dr. Keiller entirely shirks the question at issue, *viz.* whether, previously to my case, he had ever suggested the application of the caoutchouc air-bag as a plug, and whether he had ever used it as such.

Two months ago, when I wrote my paper, I had not been so fortunate as to obtain M. Gariel's Mémoire in its entirety, else I should not have done him the injustice to state that he had only applied the caoutchouc air-bag as a pessary in the treatment of uterine displacements; nor should I have attributed to Dr. Keiller the unmerited credit of having originally applied the instrument to the induction of premature labour, and to the dilatation of the passages in primipare. The extracts from M. Gariel's pamphlet, which I now send in the hope that they will appear in your columns this week, may safely be allowed to speak for themselves. M. Gariel recommends other equally ingenious and useful applications of the air-bag, and Dr. Keiller would do well to acquaint himself with them before he gives to the world his promised paper, in which it is to be hoped that he will not further stultify himself and insult the Profession, in the year 1859, by claiming originality for applications which were approved by the French Academy in 1851. M. Gariel may well feel

"annoyed by the cool assumption which Dr. Keiller has in this matter so publicly displayed."

I am, &c.

J. JARDINE MURRAY.

Brighton, July 4, 1859.

[This account of M. Gariel's bags, etc. will appear next week.—*Ed.*]

THE TITLE OF DOCTOR.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As I perceive by your issue of the 2nd instant that you are about to publish some correspondence between some practitioners of Southampton (Drs. Lake, Scott, and Aldridge), Dr. Christison and Dr. Hawkins, the Medical Registrar, respecting the right of under-graduated Licentiate of a College of Physicians to assume the title of Doctor, may I request the favour of your publishing the following official certificate, and letter from Dr. Hawkins respecting the title which I claim, and have used since the year 1842, when I returned to this country after practising as a Physician in Havana and at Porto Rico, after visiting other parts of the West Indies during 10 years of the most enterprising portion of my professional life?

I am, &c.

DAVID MCCONNELL REED, M.D.

(Registered) Licentiate of the Royal College of Surgeons, Edinburgh, 1831.

OFFICIAL CERTIFICATE.

"I hereby certify that the bearer, Dr. David McConnell Reed, has produced his diplomas, etc. at this office, and that they were carefully examined.

"If the documents, copies of which are herewith enclosed, signed by the British Consul are correct, which I must assume they are, I consider the above-named gentleman eligible for a first-class appointment in the Turkish service.

"I am, &c.

ANDREW SMITH,

Director General Army and Ordnance Medical Department.

"To His Excellency, the Turkish Minister, &c., &c., &c.

"January 10, 1855."

Medical Registration Office, 32, Soho-square, London, W. June 16, 1859.

SIR,—I have submitted your statement and the documents which you sent me to the Branch Medical Council for England. But I am instructed by the council to state that they do not feel authorised under the Medical Act to direct that your degree from Havana should be registered.

I return the documents herewith. I am, &c. FRANCIS HAWKINS.

Dr. D. M. Reed.

The circumstances of this case, which are recorded at the Foreign Office, having been submitted to the consideration of her Majesty's late Minister for Foreign Affairs, Dr. Reed was favoured with the following official note from his Lordship:

"Mr. Seymour Fitzgerald presents his compliments to Dr. Reed, and is directed by the Earl of Malmesbury to state to him that her Majesty's Minister at Madrid, has been instructed to endeavour to procure the information regarding the 'Real Junta Superior Gobernativa de Medicina, which is requested by Dr. Reed in his note of the 10th inst.

"Foreign Office, May 23, 1859."

Dr. Reed in conclusion begs to add, Mr. Editor, that he has no wish, as a legally qualified medical practitioner according to the laws of this Kingdom, and once a titled and dignified Physician according to the laws of a neighbouring kingdom, to interfere with Dr. Hawkins or any other gentleman in the conscientious and faithful discharge of the duties imposed upon him by the conditions under which he accepted office, but he merely wishes it to be understood, that, having done his best to account to the public and to the Profession for the origin of the title which he conscientiously bears, he will say no more on the subject, if you will favour him with the insertion of this communication in your widely circulated journal.

Riga Cottage, Blackheath-road, S.E. July 5, 1859.

COMMUNICATIONS have been received from:—

Professor SIMPSON; Dr. BABINGTON; Dr. HUMPHRY, Cambridge; Professor RADDI; Mr. J. J. MURRAY; Mr. MOORE, York; REGISTRAR-GENERAL; Mr. GOULD; Mr. MILLARD; Mr. MORIN; Mr. HIXTON; JUSTICE; Mr. POWER; Mr. WOOD; Mr. CLARKE; Mr. KINGDON; Mr. ASTELL; Dr. YOUNG, Edinburgh; Dr. HILDIGE, Dublin; Dr. JACO, Truro; Dr. SPENCER; Dr. MONASTIER, Edinburgh; Mr. LEWIS.

APPOINTMENTS FOR THE WEEK.

July 9. *Saturday (this day).*

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m. King's, 2 p.m.; Charing-Cross, 1 p.m.

ROYAL BOTANIC SOCIETY, 3½ p.m.

11. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.

12. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

13. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopaedic Hospital, 2 p.m.; Middlesex, 12½ p.m.

NORTH LONDON MEDICAL SOCIETY, 8 p.m.

14. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2½ p.m.

15. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

EXPECTED OPERATIONS.

King's College Hospital.—The following operations will be performed this day (Saturday):—

Mr. Fergusson—Lithotomy.

King's College, London.—Medical

DEPARTMENT.—The WINTER SESSION, 1859-60, will commence on SATURDAY, OCTOBER 1, 1859, on which day all students are expected to attend the Introductory Lecture, at Two o'clock.

The following Courses of Lectures will be given :—

Anatomy—Professor Richard Partridge, F.R.S.
Physiology; General and Morbid Anatomy—Professor Lionel S. Beale, M.B.
Chemistry—Professor W. A. Miller, M.D. F.R.S.
Principles and Practice of Medicine—Professor George Budd, M.D.
Principles and Practice of Surgery—Professor William Fergusson, F.R.S.

KING'S COLLEGE HOSPITAL.

Physicians... { George Budd, M.D. F.R.S.
R. B. Todd, M.D. F.R.S.
George Johnson, M.D.
W. A. Guy, M.B. F.R.S.
Lionel S. Beale, M.B. F.R.S. } With care of In-Patients.
With care of Out-Patients.

Physician for Diseases of Women and Children and Physician-Accoucheur—Arthur Parre, M.D. F.R.S.

Assistant-Physicians—Charles Murchison, M.D.; Conway Evans, M.B.

Surgeons ... { W. Fergusson, F.R.S.
Richard Partridge, F.R.S.
William Bowman, F.R.S.
Henry Lee, F.R.C.S. ... } With care of In-Patients.
With care of Out-Patients.

Assistant-Surgeons—John Wood, F.R.C.S.; John W. Hulke, F.R.C.S.

Surgeon-Dentist—S. Cartwright, jun.

The Hospital is visited daily. Clinical Lectures are given every week, both by the Physicians and by the Surgeons. The Physicians' Assistants and Clinical Clerks, the House-Surgeons and dressers, are selected by examination from the Students of the Hospital.

SCHOLARSHIPS.—New Students will have the privilege exclusively of contending, in October, 1859, for five Warneford Scholarships—viz., two of £25 per annum, for three years, and three of £25 per annum, for two years. The Examination will commence on the 29th of September, in Divinity, Classics (subjects the same as for the Matriculation Examination this year at the University of London), Mathematics, History, and the Modern Languages.

One Scholarship of £40, tenable for two years; one of £30, for one year; and three of £20 each, for one year, will be filled up in April next, the subjects of the Examination being exclusively Medical.

Further particulars may be obtained from J. Harley, Esq., Sub-Dean of the Department; and a detailed Prospectus will be forwarded by application to J. W. Cunningham, Esq., Secretary.

R. W. JELF, D.D., Principal.

British Medical Association. — The

TWENTY-SEVENTH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION will be held in LIVERPOOL on Wednesday, Thursday and Friday, the 27th, 28th, and 29th days of July, instant.

PRESIDENT.—W. P. ALISON, M.D., F.R.S.E., Edinburgh.

PRESIDENT-ELECT.—JAMES R. W. VOSE, M.D., Liverpool.

WEDNESDAY, 27th, 7 p.m.—First General Meeting of the Association, Address, Report of Council, and other business.

THURSDAY, 28th, 8.30 a.m.—Public Breakfast.—11 a.m.—Address in Medicine, by Dr. E. WATERS, of Chester, Cases and Papers.—ARTERXOON.—Report of Benevolent Fund, Cases and Papers.—EVENING.—Soirée at the Royal Institution, Colquitt-street.

FRIDAY, 29th, 11 a.m.—Address in Physiology, by A. T. H. WATERS, Esq., Liverpool, Cases and Papers.—6 p.m.—Dinner: Tickets, a Guinea.

It is particularly requested that all Members who propose to read papers will communicate with the General Secretary without delay.

PHILIP H. WILLIAMS, M.D., General Secretary.

Worcester, 1st July, 1859.

Addenbrooke's Hospital, in the Town

OF CAMBRIDGE.—HOUSE APOTHECARY.—NOTICE IS HEREBY GIVEN, that a SPECIAL GENERAL COURT of the PRESIDENT and GOVERNORS of the above Institution, will be held in the Board-Room of the said Hospital, at Eleven o'clock in the forenoon of the 5th SEPTEMBER next, for the ELECTION of a GENTLEMAN, to fill the office of House Apothecary, vacant by the resignation of Mr. Edmund Carver. The Gentleman elected will have to reside, and will be boarded in the Institution. The Salary is £86 a-year.

All Candidates must be duly qualified, and must forward Testimonials as to ability and character, sealed up, under cover, to the Secretary, before the 31st of August, and must produce their qualifications to the Court, on the day of Election.

And notice is hereby further given, that in case of a contest, votes will be received by the Court, at the Board-Room, from 12 o'clock at noon, until 5.30 o'clock in the afternoon of the said fifth day of September, when the Election will finally close.

Ladies only can vote by proxy, forms of which, and all particulars, may be had upon application, at the office of the Secretary.

By Rule 24 no Governor can be allowed to vote whose Subscription is unpaid; nor unless he has been a Governor for six months, except he be a benefactor of Twenty Guineas and upwards.

Annual Subscriptions became due on the 29th of September last, and as Subscriptions are paid in advance for the current year, all Governors by yearly subscription of two guineas must pay their Subscriptions up to the 29th September, 1859, together with all arrears, if any, to EDMUND JOHN MORTLOCK, Esquire, Banker, Cambridge, the Treasurer, before their votes can be received.

By order,

FREDERIC BARLOW, Secretary.

St. Andrew's-street, June 30th, 1859.

Pepsine.—M. Boudault begs to state

that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, her Majesty's Chemist, 277, Oxford-street, London, to whom all applications respecting it must be addressed.

Second Edition of Boudault on "Pepsine," with Remarks by English Physicians. Edited by W. S. SQUIRE, Ph. D., published by J. Churchill, London, may be also had of the Author, 277, Oxford-street, price Sixpence.

Freehold Mansion and beautiful Park-

like Grounds of between six and seven acres, situate at Enfield, nine miles north of London, five minutes' walk from the Railway-station. The residence contains good spacious and lofty rooms, and possesses every accommodation for a Gentleman's Establishment. The outbuildings are complete, and include lodge entrance and Two Cottages for gardener and coachman. The pleasure grounds, fruit gardens, and paddock are everything that can be desired, and so beautifully shrubbed and timbered as to form quite a miniature park. The property having been occupied by and received the care and attention of the owner for many years, is in perfect order, and offers a delightful and healthy abode for a Gentleman desirous of enjoying the charms of a country residence. Within easy distance of the city. Unless previously disposed of by private contract it will be sold by auction, by Mr. Debenham, at the Mart, on the 19th July. Full particulars and plans can be obtained at the Estate Offices, 80, Cheapside. Mr. Debenham specially and confidently recommends an inspection of this property without fear of disappointment. It is in every respect a most desirable, attractive, and healthy abode.

WOLLOMS, (from COXETER'S,) 239, Tottenham-court-road.

Health, Fresh Air, and Pure Water.

—By Her Majesty's Letters Patent.—CONDY'S FLUID contains NASCENT OXYGEN, *nature's true and only purifying agent*; instantly removes all offensive smells; renders impure water fresh, and the air pure; when diluted for use, is of a beautiful rose colour, not soiling the finest linen; is harmless, and particularly adapted for toilet use, being both refreshing and exhilarating. The Medical Profession have expressed their unqualified approbation of its merits. One gallon makes 200 gallons adapted for use. The cooling, healing, gently stimulating and invigorating properties of this Fluid render it, when diluted, a lotion possessing peculiar and valuable characteristics, whether for bathing the bodies of invalids, incorporating in poultices, or washing and healing wounds. Patronised by the Board of Health, and most public departments, hospitals, schools, and adopted by the India Council in preference to all other disinfectants. In bottles, 6d. 1s. and 2s.; stronger and purer, 1s. 2s. and 4s.

CONDY'S PATENT HEALTH POWDER also contains NASCENT OXYGEN, is odourless, and destroys all smells; in bottles, 1s. 6d. and 3s., and in casks of 1 cwt. 36s.

Wholesale agents, John Bell and Co. chemists, No. 338, Oxford-st. W.; Butler and Crisp, 5, Cheapside, St. Paul's.—Chemical works, Battersea, S.W. SAVORY and MOORE, BOND-STREET.

Scammony Manufactured from the

ROOT.—This Pure Resin may be had of all Wholesale Druggists at 28s. per lb.

The Medicinal value of this Scammony was fully explained at a meeting of the Pharmaceutical Society, and reported at length in their journal of March last, from which the following are extracts:—

"From these numerous observations, one hundred and twenty in number, together with many others which have not been tabulated, I am quite convinced that the scammony prepared by the new process from the untapped root is quite equal, as a remedy, to the very best virgin scammony which is met with in commerce, and equal, in fact, to the resin which is extracted from commercial scammony by means of ether; and it possesses this most important advantage over the scammony of commerce, namely, of being entirely free from the frauds which are almost constantly practised upon it in the country where the plant grows, and in which it has hitherto been collected, and, therefore, being perfectly uniform in its physical characters, composition and therapeutic action. There can, therefore, be no objection, but, on the other hand, manifest advantage, in employing it in place of the scammony commonly met with.

"A. B. GARROD, M.D., F.R.S., F.R.C.P.

"Professor of Materia Medica, Therapeutics and Clinical Medicine at University College; Physician to University College Hospital."

"I have endeavoured to ascertain the relative activity of Messrs. M'Andrew's scammony, and of a fine specimen of commercial virgin scammony, by prescribing these drugs alternately in equal doses to the same patient. The results, according to the judgment of myself and others who have assisted me in watching the cases, is that in most instances Messrs. M'Andrew's scammony has proved itself decidedly more active than the virgin scammony. As to pleasantness of operation, or the reverse, there seemed to be no choice between the two specimens.

"That a preparation of scammony should be a little more or a little less active is of comparatively small importance. It is far more important that the drug should have a fixed and uniform composition and activity, so that the prescriber may know, with an approach to certainty, what doses are required to produce a given effect. This advantage of uniform activity Messrs. M'Andrew's scammony seems likely to possess over the scammony which has hitherto been in common use, and which is a drug notoriously of most uncertain composition and power.

GEORGE JOHNSON, M.D., F.R.C.P.

Professor of Materia Medica and Therapeutics in King's College; Physician to King's College Hospital.

Pratt's Artificial Leg.

J. PRATT begs to call the attention of the Profession to the following Testimonial, just received:—

"Somerset,

June 20th, 1858.

"DEAR SIR,—It affords me much pleasure in being able to state that the Artificial Leg which you supplied me with is far beyond my best anticipations. From its being so LIGHT IN WEIGHT, and its action in the foot so natural, I can walk, or ride on horseback, with ease and comfort; and few indeed would detect it as being other than natural. It has given me full satisfaction.

I am, dear Sir, yours very truly,
J. W.

To Mr. J. Pratt,
Surgical Instrument Maker,
420, Oxford-street."

Crosse and Blackwell, Purveyors in

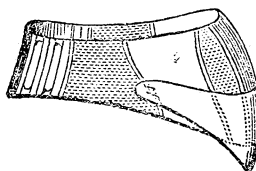

Ordinary to Her Majesty, respectfully invite attention to their PICKLES, Sauces, Tart Fruits, and other table delicacies, the whole of which are prepared with the most scrupulous attention to wholesomeness and purity. The practice of colouring pickles and tart-fruits by artificial means has been discontinued, and the whole of their manufactures are so prepared that they are not allowed to come in contact with any deleterious ingredient. A few of the articles most highly recommended are, Pickles and Tart Fruits of every description, Royal Table Sauce, Essence of Shrimps, Soho Sauce, Essence of Anchovies, Jams, Jellies, Orange Marmalade, Anchovy and Bloaters Pastes, Strascourg and other Potted Meats, and Calf's-Foot Jellies of various kinds for table use. C. and B. are also sole agents for M. Soyer's Sauces, Relish, and Aromatic Mustard; and for Carstairs' Sir Robert Peel's Sauce, and Payne's Royal Osborne Sauce. The above may be obtained of most respectable Sauce Vendors throughout the United Kingdom; and Wholesale of

CROSSE and BLACKWELL, 21, Soho-square.

Newbery's Cod-Liver Oil Cakes.

"The gingerbread is extremely light and pleasant, the flavour of the oil being completely covered."—Medical Times and Gazette, 12th February, 1859. Packets, 1s. 9d. and 3s. F. NEWBERRY and SONS (Proprietors of the "PULVIS JACOB VIER, NEWBERRY'S"), 45, St. Paul's-Churchyard, London. ESTABLISHED A. D. 1746.

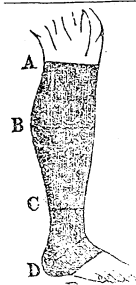

Mr. Howard, Surgeon-Dentist, 52,

FLEET-STREET, has introduced an entirely NEW DESCRIPTION OF ARTIFICIAL TEETH, fixed without Springs, Wires, or Ligatures. They so perfectly resemble the natural teeth as not to be distinguished from the original by the closest observer; they will NEVER CHANGE COLOUR or DECAY, and will be found very superior to any teeth ever before used. This method does not require the extraction of roots, or any painful operation, and will give support and preserve teeth that are loose, and is guaranteed to restore articulation and mastication; and that Mr. Howard's improvements may be within the reach of the most economical, he has fixed his charges at the lowest scale possible. Decayed Teeth stopped and rendered sound and useful in mastication.
52, Fleet-street. At home from Ten till Five.

Varicose Veins and Supporting Bands.

—SURGICAL ELASTIC STOCKINGS AND KNEE CAPS, pervious, light in texture, and inexpensive, yielding an efficient and unvarying support, without the trouble of lacing. Likewise, a strong loving priced article for Hospitals and the Working-Classes. ABDOMINAL SUPPORTING BANDS for both Sexes; those for Ladies' use, before and after accouchement, are admirably adapted for giving adequate support with extreme lightness—a point little attended to in the comparatively clumsy contrivances and fabrics hitherto employed. Instruction for measurement and prices on application, and the articles sent by post from the Manufacturers and Inventors, POPE and PLANTE, 4, Waterloo-place, Pall-mall, London, S.W.

The Profession, Trade, and Hospitals, supplied

Voullion's Patent Elastic
SPIRAL SUPPORTS, "WITHOUT SEAMS OR LACING."

SUMMER DIET.
BROWN & POLSON'S PATENT CORN FLOUR.

This is superior to anything of the kind

known—LANCET. Obtain it from Family Grocers, or Chemists, who do not substitute inferior articles. It is preferred to the best Arrow Root; for Breakfast boiled simply with milk; Dinner or Supper, in Puddings, warm or cold, Blancmange, Cake, &c., and especially suited to the delicacy of Children and Invalids. Packets, 16 oz. 8d.

NEPENTHE, OR ANODYNE TINCTURE

(OBTAINED EXCLUSIVELY FROM OPIUM),

PREPARED AT THE LABORATORY OF FERRIS, TOWNSEND, LAMOTTE, & BOORNE,
MANUFACTURING CHEMISTS AND WHOLESALE DRUGGISTS, BRISTOL.

This preparation has now been for many years extensively used by a large number of eminent members of the Medical Profession with the greatest success. It does not produce headache, stupor, giddiness, prostration of strength, constipation, or the usual unpleasant symptoms attending the use of other preparations of opium.

Nepenthe has frequently been found of essential service in cases of Cancer, where every other opiate has failed.

The following Testimonials received from Medical gentlemen in extensive practice will be regarded as satisfactory proof of its efficacy:—

MEDICAL TESTIMONIALS.

"Having prescribed your 'Anodyne Tincture' in many cases, I would strongly recommend its more general adoption. It is especially useful in the wakefulness common after parturition, or other unusual exertion or excitement. It produces a refreshing sleep, and I do not remember any case in which it has caused the objectionable effects of the other opiate preparations.

"8, Wellington-street, London-bridge, August 14, 1856.
"SAML. GRIFFITH, M.D. London, M.R.C.P.
Consulting Physician-Accoucheur to the Farringdon Dispensary,
Physician-Accoucheur to St. Thomas's Hospital, &c."

"Gentlemen,—I have great satisfaction in bearing testimony to the value of your 'Nepenthe,' in relieving suffering from disease, and in procuring sleep, where ordinary narcotics fail or disagree. For several months I have found it very effectual in relieving a great sufferer when all the ordinary anodynes had ceased to benefit, and although the dose has not been increased for months, the relief is as complete.

"'Nepenthe' is a very valuable addition to our means of relief, and the Profession and the public are greatly your debtors for it.

"I am, Gentlemen, yours obediently,

"EDWD. BECK, M.D. Cantab.
Physician to the East Suffolk Ipswich Hospital."

"To Messrs. Ferris & Co.

"Gentlemen,—'Nepenthe' has, for some time, been a favourite narcotic with me, and I infinitely prefer it to any preparation of opium now extant. It has proved a remedy of great value in all cases of Neuralgia, Chronic Rheumatism, Hypochondriacism, and indeed all affections where the use of a sedative is indicated; and in Delirium Tremens it is certainly invaluable, performing its operation upon the system, without leaving those distressing feelings consequent upon the use of opiates in general.

"I remain, Gentlemen, your obedient Servant,

"WILL. WOOD BRADSHAW, M.D. M.R.C.P. & F.R.C.S. Lond. &c. &c. &c."

Extract of a Letter from the late G. W. CAINES, Esq. M.R.C.S.

"Please to send me some 'Nepenthe,' as I have a patient with cancer in the breast, with whom no other preparation of opium agrees. I have tried them all."

"Uffculme (Devon), Feb. 16, 1854.

NEPENTHE may be procured direct from Messrs. FERRIS and CO., 4 and 5, Union-street, Bristol; from respectable Dispensing Chemists throughout the Kingdom; and from the following Agents:—

LONDON:—Mr. Thos. Keating, 79, St. Paul's-churchyard; Messrs. Evans, Lescher, and Evans, 60, Bartholomew-close; Messrs. Savory and Moore, 143, New Bond-street; Messrs. J. Bell and Co., 333, Oxford-st.
MANCHESTER:—Mr. James Woolley.
LIVERPOOL:—Messrs. Clay and Abraham; Messrs. Evans, Son, and Co.; Messrs. Clay, Dod, and Case.

BIRMINGHAM:—Messrs. Southall Bros. and Co.
YORK:—Messrs. Butterfield, Clarke and Co.
NORWICH:—Messrs. Smith and Sons.
PLYMOUTH:—Messrs. Balkwill and Co.
EXETER:—Mr. Geo. Cooper; Messrs. A. Evans and Co.
EDINBURGH:—Messrs. Raimes and Co.

As many imitations of Nepenthe have been attempted, the signature of FERRIS and COMPANY is placed over the cork of every bottle of the true preparation; and none purchased without this protection can be depended upon.

DR. DE JONGH'S

(Knight of the Order of Leopold of Belgium)

LIGHT-BROWN COD-LIVER OIL.

CAUTION.

Serious and repeated complaints having been made of a discreditable system pursued by many Chemists and Druggists of intrusively recommending or surreptitiously substituting a pale, yellow, or coarse brown preparation, when Dr. de Jongh's Oil is prescribed, the Medical Profession are respectfully and earnestly solicited to afford their assistance in counteracting and repressing a practice alike injurious to their patients and to the fair repute of a remedy now held in such high and general estimation. In all cases where this Oil cannot be procured from a respectable Chemist, application should be made to Dr. de Jongh's Agents,

ANSAR, HARFORD, & CO., 77, Strand, London, W.C.

By whom any quantity will be immediately forwarded.

WALTERS' INDIA-RUBBER URINALS.

F. WALTERS having originally invented these Urinals, begs to warn the Profession of the many bad and useless imitations which are now sold, and he would advise them, before purchasing, to look that they are stamped with his name; as, unless that be the case, he cannot guarantee them.

These conveniences are made for those who require them only occasionally, during a long journey, as well as for those invalids who use them always. Mr. WALTERS has much improved them by making them of *Etherised India-Rubber*, which adds very greatly to the strength of the India-Rubber, at the same time that it prevents its sticking together; by this means he is enabled to make them less stiff and harsh than hitherto, and yet to retain all the advantages of that stiffness. There is a patent valve, which prevents the return of the fluid; and they may be worn either sitting, walking, or lying, without the slightest inconvenience, and without being perceived by any one.

WALTERS' CONVENIENCES FOR LADIES will be found particularly useful during pregnancy. They are perfectly soft and flexible, and may be worn with perfect comfort.

All Orders must be accompanied by a Post-office order or reference.—Entrance for Ladies at the private door, where a Female attends.

MANUFACTURER OF ELASTIC STOCKINGS, BELTS, &c.

16, MOORGATE STREET, NEAR THE BANK, LONDON. E.C.

MEDICAL AGENCY.

NOTICE OF REMOVAL AND CHANGE OF FIRM.

Mr. Lara (for the last eight years the sole representative of LANE and LARA, Medical Agents and Arbitrators and Lunatic Asylum Registrars,) begs to inform the Profession that, in consequence of the daily increasing support with which he has been favoured, and for which he tenders his sincerest thanks and acknowledgments, he has taken into PARTNERSHIP Mr. James Maxfield Walters, a gentleman who has had considerable experience in the business. It will, therefore, from and after Christmas, 1858, be carried on, under the Firm of LARA and WALTERS, at 6, PUMP-COURT, Middle Temple, E.C., whither they have removed their Offices from 22, Buckingham-street, Adelphi, in order to provide that larger accommodation which a constant intercourse with a great majority of the entire body of General Practitioners in England has rendered necessary.

Partnerships and Practices sold and valued; Asylums transferred; Arbitrations effected; Assistants provided (if for a permanence without charge to Employers); and every other description of business transacted for the Profession at a fixed and moderate cost. Attendance from 11 till 4.

Medical Benevolent Fund. — The

ANNUAL GENERAL MEETING of the SUBSCRIBERS will be held at Mr. CHURCHILL'S, 11, New Burlington-street, at 3 o'clock p.m., on JULY 12th, to elect the Committee and receive the Financial Statement, &c. WILLIAM SELF, Secretary.
June 28, 1859.

India Office, April 8, 1859.—Notice is

J. COSMO MELVILL.

India Office, 5th July, 1859.—Notice

is HEREBY GIVEN, that all Candidates for Examination, as Assistant-Surgeons for H.M.'s Indian Forces, who have sent in their Certificates pursuant to the Regulations will be required to ATTEND at this OFFICE on MONDAY, the 11th July, at half past 9 o'clock. J. COSMO MELVILL.

Operations.—East India, Army and

NAVY EXAMINATIONS.—Mr. CHRISTOPHER HEATH, Demonstrator of Anatomy at the Westminster Hospital (formerly House-Surgeon to King's College Hospital), is prepared to Superintend the Performance of the Operations on the Dead Body. Fee, including an entire subject and the necessary instruments, Six Guineas; or with half a subject, Four Guineas. Apply to Mr. Heath, at the Westminster Hospital.

Royal Berks Hospital.—A Competent

DISPENSER is REQUIRED in the ROYAL BERKS HOSPITAL, READING. Salary, £25 a-year, with Board and Lodging. Applications, accompanied by Testimonials, should be sent addressed to the Secretary, at the Hospital, on or before the 25th July, from whom in the meantime, any further particulars may be learned. Reading, June 28, 1859.

North Staffordshire Infirmary, Etruria,

STOKE-UPON-TRENT.—HOUSE PUPIL WANTED.—WANTED IMMEDIATELY, for a term of three years, A HOUSE PUPIL and DRESSER. He will be required to reside in the House, and will have excellent opportunities of acquiring Medical and Surgical knowledge. For terms, &c., apply to RALPH HORDLEY, Secretary.

York County Hospital. — A Special

COURT of TRUSTEES and GOVERNORS of this Charity will be held at the Hospital, on TUESDAY, the 26th of JULY next, at One o'clock in the Afternoon, for the Election of a HOUSE-SURGEON. He must be an unmarried man. He will have to reside in the Hospital, and to undertake the whole internal management of it, under the House Committee. The salary is £100 a-year, with board and lodging. Candidates are requested to send Testimonials to my office, on or before the 9th of July. JOSH. MUNBY, Secretary.
York, June 21, 1859.

The Queen's Hospital, Birmingham.—

A MEETING of the GOVERNORS of the QUEEN'S HOSPITAL will be held on FRIDAY, AUGUST 12th, to Elect an ASSISTANT-PHYSICIAN and an ASSISTANT-SURGEON. The Governors are respectfully requested to keep their votes disengaged until the Testimonials of all the respective Candidates are fairly before them. The Testimonials to be sent in under cover, to the Secretary of the Queen's Hospital, on or before Friday, August 5th, 1859. For information respecting the duties of the appointments, application may be made to the Secretary. DAVID MALINS, Jun., Secretary.

To Surgeons. — For Immediate

DISPOSAL, a PRACTICE in a first-rate Country District, realising about £400 per annum, and capable of further extension. The Practice lies chiefly amongst the upper class, and to an active, gentlemanly man, with a fair knowledge of his Profession, would afford an unusually rare opportunity of success. The Advertiser is relinquishing his Profession and is willing to introduce a successor upon easy terms. For further particulars address by letter to Y. Z., care of Mr. Huly, chemist, Warwick.

Medical Transfer and Partnership.

30, Bucklersbury, Cheapside.

Mr. Orridge, Medical Transfer Agent,

Referee, and Valuer of Medical Property, may be consulted, at the above Address, by Gentlemen about to receive PARTNERS, or to RELINQUISH or to COMMENCE Practice.

Mr. Orridge is known to many of the Hospital Physicians and Surgeons of London.

He has been concerned professionally for a considerable proportion of the most influential Practitioners (including Partners in many of the leading Medical Firms), to whom he has the satisfaction of being permitted to refer—a privilege that he trusts will be regarded as a proof of the sincerity of his endeavours to conduct these transactions in an honourable and straightforward manner.

Gentlemen desirous of obtaining Mr. Orridge's opinion, or requiring his attendance professionally in any part of England, can obtain terms on application, by (confidentially) transmitting name and address.

Office Hours, from Eleven to Four.

Royal Maternity Charity.—

ESTABLISHED 1757—For Delivering poor Married Women at their own Habitations.

PATRON—HER MOST GRACIOUS MAJESTY the QUEEN.

In consequence of the Decease of the late Dr. Samuel Griffith, the General Committee hereby declare a VACANCY for a PHYSICIAN ACCOUCHEUR in the districts South of the River Thames. Candidates for the appointment must be Fellows or Licentiates of the Royal College of Physicians of London, and the Physician elected must reside in the appointed district. Applications and testimonials to be left on or before Saturday, the 16th of July instant, at the Office of the Charity, No. 17, Little Knightrider-street, Doctor's-commons, where full particulars may be obtained.

July 5, 1859.

JOHN SEABROOK, Secretary.

Hants County Asylum.—The appoint-

ment of ASSISTANT MEDICAL OFFICER to this Institution is now VACANT. Candidates, who must be unmarried, and duly-qualified Medical Men, are requested to forward their letters of application, stating age, together with their testimonials, to the Chairman of the Committee of Visitors, Asylum, Fareham, Hampshire, on or before WEDNESDAY, JULY 20. Salary, £100 per annum, with board, residence, and washing. Such candidates as may be selected to appear before the Committee will receive due notice of the same, and the Gentleman elected will be required to enter on his duties on or about Sept. 5. Particulars as to the duties of the Office may be obtained from the Clerk of the Asylum.

Dated 1st July, 1859.

Wanted, an In-door Assistant, to

Dispense and Visit occasionally. Salary, from £40 to £50, according to qualification. Address, A. B., F. Southgate, Esq., Solicitor, Gravesend.

Medical Partnership.—A Gentleman,

duly qualified to take a leading position in an important HIGH-CLASS PRACTICE, may find an unusual opportunity for the profitable devotion of talent and some capital, in a large Suburban Medical Establishment, either with or without water-cure. Particulars may be had of John Dawson and Son, Marlboro' Chambers, 49, Pall Mall.

For Disposal, a General Practice of

Twenty years' standing, producing £400 per annum, including appointments. Premium £400. Twelve months introduction will be given. Convenient house, good stables, walled in garden, and half-acre, with spacious premises. Rent £30 per annum. Apply to G. Cubitt, 17, Market-place, Norwich.

Insanity, Nervous Debility, &c. The

Medical Profession and the Friends of the Afflicted, are respectfully informed that they can be immediately supplied with Attendants, Male or Female, of undoubted skill, experience, and respectability, on application to the LISSON GROVE ASSOCIATION OF ATTENDANTS ON PERSONS BODILY OR MENTALLY AFFLICTED. All communications to S. BROOKES, Chemist, (Secretary,) 62, Lisson-Grove, Marylebone, London, N.W., will meet with immediate attention; and by whom Ample Testimonials can be offered in favour of the Members belonging to the above Association.—Established August 1st, 1840.

Bastick's more Certain Forms of

REMEDIES. LIQUOR COLCHICINÆ.

LIQUOR HYOSCYAMINÆ, LIQUOR SMILACINÆ, &c.

These preparations are manufactured by processes which guarantee that each dose of these liquors contains an uniform quantity of the active constituents of colchicum, hyoscyamus, and sarsaparilla respectively, in their most effective forms.

"We shall be glad to see such solutions of the active principles of our most important drugs placed in the British Pharmacopœia."—Medical Times, January 29.

The Causation and Prevention of DISEASE. With an Appendix, showing that the Sewage of Towns may be employed as a Manure, without risk, or injury to the Health. By JOHN PARKIN, M.D.

John Churchill, New Burlington-street.

Just published, Second Edition, post 8vo, cloth, 5s.
Hydropathy; or, Hygienic Medicine.

By EDWARD W. LANE, M.A., M.D. Edin.

John Churchill, New Burlington-street.

Just published, 8vo, price 2s. 6d.
Contributions to the Surgery of DISEASED JOINTS, with especial Reference to the Operation of Excision. No. 1. THE KNEE. By P. C. PRICE, Surgeon to the Great Northern Hospital, the Metropolitan Institution for Scrofulous Children at Margate, &c.

"We can highly recommend this little work to all practical Surgeons, as one which will go far towards dispelling the doubts which are entertained by some regarding the propriety of the operation in question."—Medical Times and Gazette.

"Mr. Price has done a considerable service to Surgery by publishing these observations. Next to that of his old teacher, we do not know any whose name will be more honourably connected with excision of the knee-joint than his own."—Medical Circular.

John Churchill, New Burlington-street.

Dublin: Hodges, Smith, and Co.

VOL. XL. No. 1033.—NEW SERIES, No. 472.

One Vol. 8vo, cloth lettered, price 8s. 6d.

On the Constitutional Treatment of FEMALE DISEASES. By EDWARD RIGBY, M.D., etc.

"We know of no other obstetric writer who so strongly insists on the intimate connexion between uterine and constitutional disorders, or who has carried out this principle so consistently and so successfully. On this account we look upon the work as peculiarly valuable, and calculated to do an immensity of good at the present time, by dispelling the one-sided and narrow views so generally prevalent respecting this class of diseases, and placing their pathology and treatment on a sounder and more rational basis."—Dublin Quarterly Journal of Medical Science.

London: Renshaw, 356, Strand.

GALBRAITH AND HAUGHTON'S NEW SERIES OF SCIENTIFIC MANUALS.

On Thursday next will be published, in fcp. 8vo, with numerous Woodcut Illustrations, price 2s. sewed,

Illustrations engraved on wood,

The Dog in Health and Disease:
Comprising the various modes of Breaking and using him for
Hunting, Coursing, Shooting, &c.; and including the Points or Charac-
teristics of Toy Dogs. By STONEHENGE, author of the "The Grey-
hound," &c.
London: Longman, Green, Longman, and Roberts.

Just Published, Price 3s. 6d., with 200 Descriptive Cases, and
Illustrations in Chromo-Lithography,

Amputations and Artificial Legs,
HANDS, &c. By W. R. GROSSMITH, of 175, Fleet-street, London.
"Mr. Grossmith has offered some good practical suggestions for the con-
sideration of the operator, and has entered more fully into the subject
than has hitherto been attempted."—The Lancet, Nov. 14th, 1857.
"Mr. Grossmith's artificial limbs are well constructed, and on the best
system."—Paris Exposition Jury Reports.
London: Longman and Co. Dublin: Fannin and Co.; and from the
Author, post free.

Now ready, price 5s. 6d., or free by post to any part of the United King-
dom, price 6s., Fourth Edition, greatly enlarged and improved,

A Grammatical Introduction to the
LONDON PHARMACOPEIA, and a KEY to PHYSICIANS' PRE-
SCRIPTIONS. By F. S. LEACH.
"This little work will be found extremely useful to students who have
received but an imperfect classical education."—The Lancet.
Hughes and Butler, Medical Booksellers and Publishers, 15, St. Mar-
tin's-le-Grand.

Now ready, in One Vol. 8vo, pp. 370, price 7s. 6d.

A Treatise on Medical Electricity,
Theoretical and Practical; and its Use in the Treatment of Para-
lysis, Neuralgia, and other Diseases. By J. ALTHAUS, M.D.
Trübner and Co. 60, Paternoster-row.

Just published, in one volume, royal 8vo, pp. 992, handsomely bound in
cloth, price 18s.

A Dictionary of Medical Science. By
A ROBLEY DUNGLISON, M.D. LL.D. Fifteenth Edition, revised
and very greatly enlarged.
It reviewing the fourteenth edition of this celebrated work, the
"British and Foreign Medico-Chirurgical Review," for July 1853, page 205,
remarked, that the labour which had been bestowed upon the work
"had been something prodigious," adding, "the work, however, has
been now done, and we are happy in the thought that no human being
will have again to undertake the same gigantic task. Revised and
corrected from time to time, Dr. Dunglison's 'Medical Lexicon' will last
for centuries."
Yet, in the present edition, not only has the work been revised and
corrected, but about six thousand subjects and terms have been added,
which are not to be found in the one noticed by the "British and
Foreign."
Trübner and Co., 60, Paternoster-row, London.

TO SURGEONS, APOTHECARIES, AND DRUGGISTS.

Important Saving, by Prepayment,
in the PURCHASE of
NEW WHITE ROUND MOULDED VIALS OF THE BEST QUALITY.
PELLATT and Co. submit the following PRICES of VIALS, for PRE-
PAYMENT only:—

<p> $\frac{1}{2}$ oz., 1 oz., 10 dr., and $1\frac{1}{2}$ oz. per Gross, 6s. 14 dr., and 2 oz. " 7s. 3 oz. " 8s. 4 oz. " 10s. 6 oz. " 15s. 8 oz. " 18s. </p>	<p> In quantities of not less than Six Gross, assorted to suit the convenience of the purchaser, delivered to carriers in London. No charge for Package. Breakage at risk of Pur- chaser. </p>
--	--

$\frac{1}{2}$ oz. graduated in 8 doses, " 12s. 6d.)
The above Prices being based upon a calculation which excludes all
charges whatever between the Manufacturer and the Consumer, no atten-
tion can be paid to any order not accompanied by a remittance in full,
made payable in London.—P. and Co. do not supply Green Glass.—Orders
and remittances to be addressed,

PELLATT & Co.,
FALCON GLASS WORKS, LONDON.

Best Iron Wire, prepared expressly by
COCKER BROTHERS, NURSERY-STREET, SHEFFIELD, for
SURGICAL PURPOSES, as supplied to Professor Simpson, Edinburgh;
Dr. Churchill, Dublin; Mr. T. Spencer Wells, London; Dr. Bozeman,
Montgomery, U.S.; and many others.—See Professor Simpson's Lecture
in Medical Times, January 1st, 1859.

"PULVIS JACOBI VER., NEWBERRY'S."

Diphtheria, Fevers, Hooping Cough,
&c.—We beg to caution the Profession against imitations of this
invaluable Medicine, for so many years prescribed as "Pulvis Jacobi Ver,"
but to which it is now necessary to add the name "NEWBERRY'S," to secure
prescribers against the SUBSTITUTION of articles advertised as James'
Powder, BUT WHICH HAVE NOTHING IN CHARACTER, DOSE, OR EFFECT, with
the original article, which has been prepared at 45, St. Paul's-churchyard,
continuously since its introduction in 1746.
Price: 1 oz. bottles, 11s.; $\frac{1}{2}$ oz. do. 4s. 6d., with the usual allowance
to the Profession. (Signed) F. NEWBERRY & SONS.

Struve's Seltzer, Marienbad, Vichy,
KISSINGEN, and other MINERAL WATERS.—Under her Majesty's
special Patronage.—ROYAL GERMAN SPA, BRIGHTON, STRUVE'S
PUMP-ROOM and PROMENADES, offering every facility for a Course of
Mineral Waters, as perfect and beneficial as at the natural springs, are
NOW OPEN, for the Thirty-fifth Season. A prospectus, with the highest
Medical testimonials, may be obtained gratis, at the Pump-room, or from
George Waugh and Co. Chemists to the Queen, 177, Regent-street (westside),
London, and other re-pectable houses in London and the provincial towns,
where orders for Struve's Bottled Mineral Waters continue to be executed.
CAUTION.—The success obtained by Struve's Mineral Waters, owing to
their perfect identity with those of the natural springs, has induced
several parties to attempt imitations, sold as "Brighton Seltzer,"
"Brighton Vichy," &c., an analysis of some of which has shown an utter
disregard of their true chemical composition. To distinguish Struve's
Waters from all others, every bottle has a label and red ink stamp over
the cork, each bearing Struve's name, without which name none is
genuine, though contained in Struve's old bottles.

Great Reduction in the Prices of New
MEDICAL GLASS BOTTLES and PHIALS, at the Islington
Glass Bottle Works, Islington-place, Park-road. London Warehouses,

the goods are received. Packages free. Goods delivered free within 7
miles. Post-office orders made payable to E. and H. HARRIS and Co.,
at the Chief Office, London. Bankers: Union Bank of London.
N.B.—Orders sent to either Establishment will have prompt attention.

Health, Fresh Air, and Pure Water.
—By Her Majesty's Letters Patent.—CONDY'S FLUID contains
NASCENT OXYGEN, nature's true and only purifying agent; instantly
removes all offensive smells; renders impure water fresh, and the air
pure; when diluted for use, is of a beautiful rose colour, not soiling the
finest linen; is harmless, and particularly adapted for toilet use, being
both refreshing and exhilarating. The Medical Profession have expressed
their unqualified approbation of its merits. One gallon makes 200 gallons
adapted for use. The cooling, healing, gently stimulating and invigorating
properties of this Fluid render it, when diluted a lotion possessing pecu-
liar and valuable characteristics, whether for bathing the bodies of invalids,
incorporating in poultices, or washing and healing wounds. Patronised
by the Board of Health, and most public departments, hospitals, schools,
and adopted by the India Council in preference to all other disinfectants.
In bottles, 6d. 1s. and 2s.; stronger and purer, 1s. 2s. and 4s.
CONDY'S PATENT HEALTH POWDER also contains NASCENT
OXYGEN, is odourless, and destroys all smells; in bottles, 1s. 6d. and 3s.,
and in casks of 1 cwt. 36s.
Wholesale agents, John Bell and Co. chemists, No. 338, Oxford-st. W.;
Butler and Crisp, 5, Cheapside, St. Paul's.—Chemical works, Battersea, S.W.
SAVORY and MOORE, BOND-STREET.

WINES FROM SOUTH AFRICA.

Denman, Introducer of the South
AFRICAN PORT SHERRY, &c. 20s. PER DOZEN, BOTTLES INCLUDED.
A PINT SAMPLE OF EACH FOR 24 STAMPS.
Wine in cask forwarded free to any Railway-station in England.
(Extract from the Lancet, July 10, 1858.)

"THE WINES OF SOUTH AFRICA.—We have visited Mr. Denman's
stores, selected in all eleven samples of wine, and have subjected them
to careful analysis. Our examination has extended to an estimation
of their bouquet and flavour, their acidity and sweetness, the amount of
wine stone, the strength in alcohol, and particularly to their purity. We
have to state, that these wines, though brandied to a much less extent
than Sherries, are yet, on the average, nearly as strong; that they are
pure, wholesome, and perfectly free from adulteration; indeed, consider-
ing the low price at which they are sold, their quality is remarkable."

EXCELSIOR BRANDY, Pale or Brown, 15s. per gallon, or 30s. per dozen.
Terms Cash. Country orders must contain a remittance. Cross cheques
"Bank of London." Price Lists, with Dr. Hassall's analysis, forwarded
on application.

JAMES L. DENMAN, 65, Fenchurch-st., corner of Railway-place, London.

PURE SPIRITS FOR THE FACULTY.

S. V. R. 56 o.p., 17s. net Cash.—

This quotation admits of neither credit nor discount, and 1s. per gallon must be added for packages, to be allowed on their return.

HENRY BRETT and CO., Old Furnival's Distillery, Holborn.

Microscopic Glass.—Thin Glass for

Mounting Objects, in squares or circles. Slides 3 in. by 1 in. and Cells of every kind, supplied Wholesale and Retail, by
CLAUDET and HOUGHTON, 89, High Holborn, London.

Newbery's Cod-Liver Oil Cakes.—

"The gingerbread is extremely light and pleasant, the flavour of the oil being completely covered."—Medical Times and Gazette, 12th February, 1859. Packets, 1s. 9d. and 3s. F. NEWBERY and SONS (Proprietors of the "PULVIS JACOBI VER. NEWBERY'S"), 45, St. Paul's-Churchyard, London. ESTABLISHED A. D. 1746.

Dr. Caplin's Electro-Chemical Bath

ESTABLISHMENT, 9, YORK PLACE, BAKER STREET, PORTMAN SQUARE, for the extraction of Mercury, and other Metallic or Extraneous Substances, and the Treatment of Chronic Diseases. For the demonstration of this new system, *vide* the Second Edition, price 1s., 8vo, of Dr. Caplin's Treatise on the Electro-Chemical Bath, and the Relation of Electricity to the Phenomena of Life, Health, and Disease. Sold at the Author's Establishment.

NO LIVE STOCK ON BOARD SHIP.

Joints of Beef and Mutton, also Poultry,

are now Preserved by HAND'S PATENT. That they will keep quite fresh in an uncooked state in all climates, and when eaten cannot be known from fresh-killed food, cooked meat need not now be taken.

For prices or samples apply to Mr. HESKETH S. DAVIS, 24, Leadenhall-street, London, E.C.

Superphosphate of Iron and Super-

PHOSPHATE OF IRON AND LIME. New Remedial Agents introduced to the notice of the Profession at the Meetings of the Medical Society of London, and now extensively employed by the most eminent members of the Medical Profession. The Syrup is the most eligible mode of administering these valuable Remedial Agents. Mr. GREENISH will be happy to forward a variety of cases which have been furnished to him, where its success has been most marked, and which will serve to indicate where it may be most advantageously employed.—20, New-street, Dorset-square.

Bastick's more Certain Forms of

REMEDIES. LIQUOR COLCHICINÆ, LIQUOR HYOSCYAMINÆ, LIQUOR SMILACINÆ, &c.

These preparations are manufactured by processes which guarantee that each dose of these liquors contains an uniform quantity of the active constituents of colchicum, hyoscyamus, and sarsaparilla respectively, in their most effective forms.

"We shall be glad to see such solutions of the active principles of our most important drugs placed in the British Pharmacopœia."—Medical Times, January 29.

Pharmaceutical Laboratory, 2, Brook-street, Bond-street, London.

Varicose Veins and Supporting Bands.

—SURGICAL ELASTIC STOCKINGS AND KNEE CAPS, per se, light in texture, and inexpensive, yielding an efficient and unvarying support, without the trouble of lacing. Likewise, a strong low-priced article for Hospitals and the Working-Classes. ABDOMINAL SUPPORTING BANDS for both Sexes; those for Ladies' use, before and after accouchement, are admirably adapted for giving adequate support with extreme lightness—a point little attended to in the comparatively clumsy contrivances and fabrics hitherto employed. Instruction for measurement and prices on application, and the articles sent by post from the Manufacturers and Inventors, POPE and PLANTE, 4, Waterloo-place, Pall-mall, London, S.W.

The Profession, Trade, and Hospitals, supplied

Williams and Son's Pure Glycerine

SOAP. Analysed by Dr. Hofmann, F.R.S., and Professor Redwood, Ph.D., strongly recommended by many eminent members of the Medical Profession, and favourably noticed by the following Medical Journals:—

THE LANCET.
THE MEDICAL TIMES AND GAZETTE.
THE BRITISH MEDICAL JOURNAL.
THE MEDICAL CIRCULAR.
EDINBURGH MEDICAL JOURNAL.
THE DUBLIN HOSPITAL GAZETTE.

It is suited to all cases of delicate skin (whether arising from disease or otherwise), and is admirably adapted for nursery use. May be had of all respectable Chemists, Perfumers, &c.

SOAP-WORKS, CLERKENWELL, LONDON, E.C.

Great Saving in the Purchase of New

POULTICES SUPERSEDED! SPONGIO PILINE.

The Profession are respectfully

informed, that the WANDLE FELT COMPANY having purchased Mr. MARKWICK'S PATENT for the well-known SPONGIO PILINE, for the application of moist heat, in lieu of Poultries and Fomentations, and the IMPERMEABLE PILINE, for Rheumatism, for promoting perspiration, and for the application of stimulating liniments, are now supplying these articles, of superior manufacture, and at greatly reduced prices, at 27, BEDFORDBURY, COVENT-GARDEN, London, and also through the Wholesale and Retail Druggists in town and country.

Pillischer's Achromatic Microscopes.—

To meet the daily increasing demand for his Microscopes, M. PILLISCHER has recently completed extensive alterations in his workshops to enable him to manufacture MICROSCOPES and their Object Glasses upon a more expeditious and extensive scale. M. P. has the pleasure of informing the Profession that he is now able to furnish Microscopes of the very greatest perfection; possessing every modern improvement; and with Object Glasses of a quality unsurpassed by any other maker, on the shortest notice, and at very moderate prices.

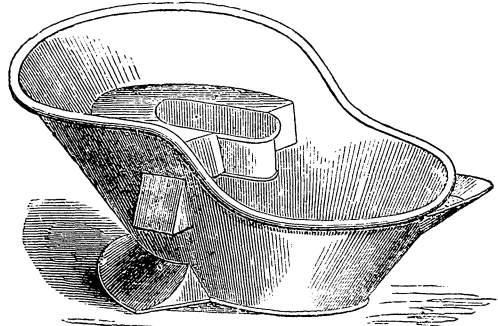

PILLISCHER'S £7 7s. STUDENTS' MICROSCOPE,

for which a prize Medal was awarded to him at Paris Exhibition, 1855, deserves particular notice. It consists of a well-constructed Stand, with coarse and fine adjustments, a capital Stage, with Diaphragm and Large Mirror, one Eye-glass, one and one quarter inch Object Glasses, 16" and 75" angular aperture, and a neat Mahogany Case about 7 in. square. The above Microscope when further completed with the addition of a Second Eye-glass, Condenser for Opaque Objects, Live Box, Stage Forceps, large Glass Stage, and Polarising Apparatus, price £10, forms a most complete and valuable Microscope, and in every respect as useful as a much more expensive one.

A Catalogue post free on application to M. Pillischer, Optician, 88, New Bond-street, London, W.

Oxley's Patent Multum-in-Parvo Bath.

Sole Makers, GRIFFITHS and BROWETT, 68, BRADFORD-STREET, BIRMINGHAM; and to be had of all respectable Ironmongers.

The convenience of a Bidet, Sponge, Hip, Foot, and Nursery Bath are here combined, which renders it not only the best for general purposes, but indispensable for the invalid, to whom it may confidently be recommended by members of the Medical Profession as the most comfortable and useful Bath extant.

King's College, London.—Medical

DEPARTMENT.—The WINTER SESSION, 1859-60, will commence on SATURDAY, OCTOBER 1, 1859, on which day all students are expected to attend the Introductory Lecture, at Two o'clock.

The following Courses of Lectures will be given:—

Anatomy—Professor Richard Partridge, F.R.S.
Physiology; General and Morbid Anatomy—Professor Lionel S. Beale, M.B.
Chemistry—Professor W. A. Miller, M.D. F.R.S.
Principles and Practice of Medicine—Professor George Budd, M.D.
Principles and Practice of Surgery—Professor William Fergusson, F.R.S.

KING'S COLLEGE HOSPITAL.

Physicians... { George Budd, M.D. F.R.S.
R. B. Todd, M.D. F.R.S.
George Johnson, M.D.
W. A. Guy, M.B. F.R.S.
Lionel S. Beale, M.B. F.R.S. } With care of In-Patients.
Physician for Diseases of Women and Children and Physician-Accoucheur—Arthur Farre, M.D. F.R.S.
Assistant-Physicians—Charles Murchison, M.D.; Conway Evans, M.B.
Surgeons ... { W. Fergusson, F.R.S.
Richard Partridge, F.R.S.
William Bowman, F.R.S.
Henry Lee, F.R.C.S. ... } With care of In-Patients.
Assistant-Surgeons—John Wood, F.R.C.S.; John W. Hulke, F.R.C.S.
Surgeon-Dentist—S. Cartwright, jun.

The Hospital is visited daily. Clinical Lectures are given every week, both by the Physicians and by the Surgeons. The Physicians' Assistants and Clinical Clerks, the House-Surgeons and dressers, are selected by examination from the Students of the Hospital.

SCHOLARSHIPS.—New Students will have the privilege exclusively of contending, in October, 1859, for five Warneford Scholarships—viz., two of £25 per annum, for three years, and three of £25 per annum, for two years. The Examination will commence on the 29th of September, in Divinity, Classics (subjects the same as for the Matriculation Examination this year at the University of London), Mathematics, History, and the Modern Languages.

One Scholarship of £40, tenable for two years; one of £30, for one year; and three of £20 each, for one year, will be filled up in April next, the subjects of the Examination being exclusively Medical.

Further particulars may be obtained from J. Harley, Esq., Sub-Dean of the Department; and a detailed Prospectus will be forwarded by application to J. W. Cunningham, Esq., Secretary.

R. W. JELF, D.D., Principal.

British Medical Association.—The

TWENTY-SEVENTH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION will be held in LIVERPOOL on Wednesday, Thursday and Friday, the 27th, 28th, and 29th days of July, instant.

PRESIDENT.—W. P. ALISON, M.D. F.R.S.E., Edinburgh.

PRESIDENT-ELECT.—JAMES R. W. VOSE, M.D., Liverpool.

WEDNESDAY, 27th, 7 p.m.—First General Meeting of the Association, Address, Report of Council, and other business.

THURSDAY, 28th, 8.30 a.m.—Public Breakfast.—11, a.m.—Address in Medicine, by Dr. E. WATERS, of Chester, Cases and Papers.—AFTERNOON.—Report of Benevolent Fund, Cases and Papers.—EVENING.—Soirée at the Royal Institution, Colquitt-street.

FRIDAY, 29th, 11 a.m.—Address in Physiology, by A. T. H. WATERS, Esq., Liverpool, Cases and Papers.—6 p.m.—Dinner: Tickets, a Guinea.

It is particularly requested that all Members who propose to read papers will communicate with the General Secretary without delay.

PHILIP H. WILLIAMS, M.D., General Secretary.

Worcester, 1st July, 1859.

Association of Medical Officers of

ASYLUMS AND HOSPITALS FOR THE INSANE.—The ANNUAL MEETING will take place at LIVERPOOL, on TUESDAY, the 26th of JULY, 1859, under the Presidency of Sir CHARLES HASTINGS, D.C.L.

The day of Meeting has been fixed by the Committee, in order to suit the convenience of Members attending the Annual Meeting of the British Medical Association at Liverpool, on the 27th, 28th, and 29th of July.

The Meeting will be held in the Rooms of the Medical Institution, Mount Pleasant, Liverpool, at 12 noon, precisely. The meeting will commence with an Address from the President, Sir Charles Hastings, D.C.L. The general business of the Association will afterwards be taken.

The Secretary has received intimation from Dr. Conolly, that several Foreign Psychologists will be proposed by him as Honorary Members. The Committee invite the attendance of the Profession in Liverpool.

The Dinner will take place at Seven precisely, at Radley's Adelphi Hotel. Members proposing to dine are particularly requested to forward their names to Mr. Radley.

Members of the Profession desirous of admission into the Association are requested to communicate with the Honorary Secretary before the day of Meeting.

Notice of communications, and of subjects for discussion at the Annual Meeting, may be made to the Honorary Secretary.

Members of the Committee are requested to meet at the Medical Institution, at eleven o'clock precisely, on the day of Meeting.

The Rules of the Association, as adopted at the Annual Meeting, 1855, can be had on application to the Honorary Secretary.

C. LOCKHART ROBERTSON, M.B., Cantab., Hon. Sec.

Hayward's Heath, Sussex, 1st July, 1859.

The Queen's Hospital, Birmingham.—

A MEETING OF THE GOVERNORS OF THE QUEEN'S HOSPITAL will be held on FRIDAY, AUGUST 12th, to Elect an ASSISTANT-PHYSICIAN and an ASSISTANT-SURGEON. The Governors are respectfully requested to keep their votes disengaged until the Testimonials of all the respective Candidates are fairly before them. The Testimonials to be sent in under cover, to the Secretary of the Queen's Hospital, on or before Friday, August 5th, 1859. For information respecting the duties of the appointments, application may be made to the Secretary.

DAVID MALINS, Jun., Secretary.

Queen's College, Birmingham.—

FACULTY OF MEDICINE.—The WINTER SESSION will open OCTOBER 3rd, 1859.

Anatomy—Professor Furneaux Jordan, M.R.C.S.

Physiology—Professor Waller, M.D., F.R.S., Physician to the Queen's Hospital.

Surgery—Professor Sands Cox, F.R.S., F.R.C.S., Senior Surgeon to the Queen's Hospital.

Practice of Medicine—Professor W. F. Wade, M.B., B.A., T.C.D., Physician to the General Dispensary.

Chemistry—Professor Bond, M.B., B.A. Lond., F.C.S., Physician to the Queen's Hospital.

Practical Anatomy—Under the superintendence of Professor Jordan and Dr. Walker.

Resident Medical Tutor—T. J. Walker, Esq., M.B. Lond., University Medical Scholar.

Clinical Medicine at the Queen's Hospital by Professors Sands Cox, Langston Parker, J. S. Gamgee, and J. F. West.

Clinical Surgery at the Queen's Hospital by Professors Alexander Fleming, M.D., Augustus Waller, M.D., and Francis Bond, M.B.

The College is situated midway between the Queen's and General Hospitals, and is open to the students of both.

The Junior Department in Medicine is open to students about the age of sixteen, and its studies are specially devoted to preparation for the Preliminary Examinations of the various Universities and Medical Boards, and to the acquisition of a knowledge of the elements of Anatomy, Chemistry, Botany, &c.

The Faculties of Arts, Law, Engineering, Agriculture, and Theology, will also resume at the same period.

For further information and Prospectuses, application may be made to the Honorary Secretary to the Medical Faculty, Dr. Bond, Queen's College.

An Appeal is made to the British

Public by the WIDOWED MOTHER of the LATE Mr. R. B. POWER, ASSISTANT-SURGEON, R.N., who was her only child and entire support in life. His death was caused by arduous duties in the Crimean war (as stated in Medical certificate). He was ten years in the service; was at the battle of the Alma, where he saved the lives of twenty-five men, who would have otherwise been left as dead; was at the storming of the forts of Sebastopol in H.M.S. "Sanspareil," when eleven were killed and sixty-one wounded, and sixteen capital operations had to be performed, he being the only Assistant-Surgeon on board, was at Balacava during the winter where he attended professionally French, Turks, and Russians, never flinching from the most painful and self-denying duties. He received the personal thanks of Lord Lyons, a testimonial from the Inspector of the fleet, and a strong recommendation from Captain Davies his commanding officer to the Admiralty for his services. The Admiralty have been memorialised in vain. The Patriotic Fund also applied to without relief, the claims of a Widowed Mother not coming under the rules of either.

It therefore only remains for Mrs. Power under her deep affliction in mind, body, and estate, to apply to a generous public and commit her case to Him who openeth and no man shutteth, in the humble confidence that He will incline some sympathising hearts to aid her in this her time of great need. Mrs. Power has had three uncles who held commissions in the army, one of whom was killed in battle. Certificates may be seen and subscriptions received at the London and Westminster Bank, Lothbury, or by Mrs. Power at 43, Torrington-square, W.C.—4th July, 1859.

For Infants.—The British Feeding

BOTTLE (registered) may be placed in any position without the Food running out. The supply can be regulated by a stop-cock; being electroplated, it may be instantaneously cleaned. Unlike wood, ivory, or bone, it is impervious to moisture, cannot crack or become sour; there is no possibility of the infant drawing air with the food.

By W. T. COOPER, Pharmaceutical Chemist, 26, Oxford-street, London.

Price 7s. 6d., or free to any Railway Station, 8s. 6d.

IMPORTANT TO THE PROFESSION.

Crosse and Blackwell, Purveyors in

Ordinary to Her Majesty, respectfully invite attention to their PICKLES, Sauces, Tart Fruits, and other table delicacies, the whole of which are prepared with the most scrupulous attention to wholesomeness and purity. The practice of colouring pickles and tart-fruits by artificial means has been discontinued, and the whole of their manufactures are so prepared that they are not allowed to come in contact with any deleterious ingredient. A few of the articles most highly recommended are, Pickles and Tart Fruits of every description, Royal Table Sauce, Essence of Shrimps, Soho Sauce, Essence of Anchovies, Jams, Jellies, Orange Marmalade, Anchovy and Bloaters Pastes, Strasbourg and other Potted Meats, and Calf's-Foot Jellies of various kinds for table use. C. and B. are also sole agents for M. Soyer's Sauces, Relish, and Aromatic Mustard; and for Carstairs' Sir Robert Peel's Sauce, and Payne's Royal Osborne Sauce. The above may be obtained of most respectable Sauce Vendors throughout the United Kingdom; and Wholesale of

CROSSE and BLACKWELL 1 Soho-square.

ORIGINAL LECTURES.

CLINICAL LECTURES

ON

THE DISEASES OF WOMEN.

By J. Y. SIMPSON, M.D. F.R.S.E.

Professor of Medicine and Midwifery in the University of Edinburgh.

LECTURE XVIII. *Continued.*—ON PELVIC CELLULITIS.

THE SYMPTOMS AND DIAGNOSIS OF THE DISEASE.

You will find that the symptoms of pelvic cellulitis differ according as you meet with the disease at a period before suppuration has begun, or after it has become established. They are, therefore, divisible into two groups, which must be considered separately.

A. BEFORE SUPPURATION HAS BEGUN.

1. *Inflammatory Fever.*—In its earliest stages the disease is marked by fever of greater or less intensity, which is usually ushered in by rigors, more especially in puerperal females, in whom it sometimes occurs as one of the forms or complications of puerperal fever. In non-puerperal patients the fever is usually of a highly inflammatory type—the strong rapid pulse, the hot skin, the furred tongue, and all the ordinary constitutional phenomena of a well-marked synocha being present. Along with these general febrile symptoms you have various local symptoms, such as,

2. *Pains in the Pelvis.*—These pelvic pains are experienced more especially in those organs beside or around which the inflammation has been set up, and they are due to the pressure exerted on the particular organ by the matter effused in its vicinity. One of the most common symptoms of the occurrence of pelvic cellulitis is dysuria, from the pressure of the inflammatory tumour on the bladder or on its neck; and whenever you find a patient labouring under a smart fever, and complaining of frequent desire for micturition, and pain in passing water, it will be your duty at once to ascertain if the symptoms be not due to a commencing attack of pelvic cellulitis. Or, again, the patient may suffer from pain in defæcation, when the inflammation is set up in the cellular tissue around the rectum, and leads to the effusion of fluids there, as has happened in the case of one of our Hospital patients. You have, then, symptoms of distress in the bladder and rectum when these organs are emptied, accompanied generally by a constant throbbing pain in the pelvis; and if these are attended with a marked degree of fever and constitutional disturbance, you may be pretty certain that pelvic cellulitis has set in. But you can only make yourself perfectly certain of the fact by instituting a physical examination, and ascertaining the existence of a,

3. *Tumour in the Pelvis.*—This is to be felt by examining with the forefinger of the right hand through the vagina or the rectum, palpation or pressure being exercised at the same time with the fingers of the left hand over the inlet of the pelvis. On making an exploration in this manner you can detect a swelling, usually at first more or less oblong or rounded in form, but sometimes modified by the form and density of the fascial layers which invest and limit it. Commonly it is firm and hard, but exquisitely tender to the touch, and it rapidly increases in size and density. If the disease be checked at this stage, such a tumour may be resolved, and all the attendant symptoms may gradually subside and disappear; and this is what actually occurs in perhaps about a-half, or indeed more, of all the cases of pelvic cellulitis. But in the remainder the disease is of longer continuance, and leads to further changes, chiefly from the development of pus in the part; and as these are the cases which often come alone under our care, and which remain longest under treatment, it becomes a matter of importance to know how to recognise the disease,

B. AFTER SUPPURATION HAS BEEN ESTABLISHED.

When the disease has reached this stage you have still

VOL. XL. No. 1033—NEW SERIES, No. 472.

fever, pain and intumescence, but all more or less altered in character. Pains that had for a time subsided may now return. Thus it not infrequently happens that the dysuria which marked the onset of the disease disappears for a time when the bladder has become accustomed to the pressure of the inflammatory tumour, but recurs when suppuration is set up. Or the patient may begin to experience pain in other parts where formerly none was felt; and cases of pelvic cellulitis have sometimes come to be treated as cases of sciatica of an aggravated type from the pressure of the pus in the sciatic nerve, as it makes its way along it through the great sciatic notch, or from implication of the nerve in the inflammatory process. There is a state of the limbs on the side principally attacked which is not common, but still highly worthy of your remembrance. When the inflammatory effusion is located principally or solely in the cellular tissue of one of the iliac fossæ, and around the muscles there passing downwards to the thigh, the lower extremity on that side occasionally becomes drawn up, and cannot, without extreme suffering,—or, indeed, cannot at all,—be retracted and extended. I have seen this symptom principally in cases of puerperal Pelvic Cellulitis. The tumour, too, is changed, and instead of being hard and brawny, it assumes betimes, and first in one or more central points, the fluctuating feeling of a fluid collection. In addition to the changes which occur in the pre-existing symptoms, however, some entirely new symptoms develop themselves and demand our notice. Such is,

4. *Hectic Fever.*—Instead of the constantly high and bounding pulse and the equally elevated temperature of the skin characteristic of continued inflammatory fever, you will find the patient becoming subject to remissions and exacerbations of the fever. Hectic fever is established, and I have seen more than one case of the disease being actually mistaken for phthisis. The pulse becomes weaker and softer, though still very rapid; she has occasional slight rigors, and the fever becomes more intense in the evenings. The skin is still generally hot, but it becomes cold at times, and at other times it is covered with profuse perspiration, more particularly when the patient sleeps. She is gradually and occasionally rapidly reduced in strength, and comes to present an appearance which it is not easy to describe, but which is almost pathognomic of the establishment of suppuration. You will find Mr. Travers telling of Sir Astley Cooper, that he was called on one occasion to see a patient in the country, and whenever he went into the room and looked at the patient he at once put the question to the medical attendants, "Where is the matter?" It had not before been suspected that suppuration had occurred, but on more careful examination the facial diagnosis so promptly made was fully confirmed, for, under the pectoral muscle a large abscess was discovered, which Sir Astley at once evacuated, and so cured the patient. It is difficult, I say, to describe in so many words, the expression of countenance assumed by patients who are suffering from collections of pus in any parts of the body; but you must go and observe it for yourselves in the wards of the Hospitals, and when once you have learned to recognise it, you will find it to be a sign of great value in enabling you to form a just conclusion as to the nature of many an otherwise obscure or doubtful case. Then, in endeavouring to make up your mind as to the presence of pus in a case of pelvic cellulitis, you will sometimes be enabled to come to a determination on this point, by taking into consideration the length of time during which the inflammation has existed. For, if inflammation have been going on in the cellular tissue of the pelvis for three or four weeks, and little, or indeed, no abatement has taken place in the severity of the symptoms, but only such changes as I have been attempting to point out, you may be almost certain that by that time the inflammatory process has reached such a stage as to have led to the development of pus. That such is in reality the case, however, you can become absolutely certain by noticing,

5. *The Feeling of Fluctuation.*—The spot at which you will most frequently be able to recognise the feeling of fluctuation for the first time in most cases of pelvic cellulitis, is in the roof of the vagina immediately behind the cervix uteri, or to one side, as if where the broad ligament would open and split below if its layers were separated by accumulated fluid. From some peculiar arrangement of the layers of the pelvic fascia, when pus is formed in the course of a pelvic cellulitis occurring in the upper half of the true cavity of the pelvis—and this, you must remember, is the most frequent

seat of the disease—it has a tendency always to point in this direction and to find an exit for itself, either at the lower base of the broad ligaments, or in the posterior cul-de-sac of the vault of the vagina; and it is at these spots, where the fascial layer seems to be unusually thin and weak, that the feeling of fluctuation is ordinarily first to be detected. But in cases where the pus has been formed, but is too deeply seated to allow of your discovering its presence by the sense of touch, you must have recourse to some other means to assure yourself of its existence. The best means that you can employ with this view is,

6, *The introduction of an exploring-needle into the centre of the tumour.* This instrument, which is of invaluable service in the examination of diseases, is never used to more advantage than when employed for the exploration of pelvic abscesses, when they happen to be unusually difficult or doubtful in their diagnosis. For in the common run of cases you will usually be perfectly able to make out the diagnosis without this assistance. In any case, however, of pelvic cellulitis where you are in doubt as to the formation of pus, and have reasons for being certain of its presence, you may make sure of it at once by pushing an exploring needle into the centre of the tumour. The instrument has, perhaps, been neglected too much as a means of diagnosis in Surgery, when we consider with what freedom from danger its employment is attended, and how frequently abscesses, aneurisms, and other tumours have been confounded together, when by its use such mistakes could easily have been avoided. I know of a case where a distinguished Surgeon introduced an exploring-needle into a tumour in the groin, under the belief that it was a bubo, and to prove to others present that it was so; but, to his astonishment, no pus escaped, and instead a quantity of air. It was a crural hernia, the sac of which had become inflamed, and into it he thrust the exploring-needle, and thus saved himself from committing the fatal mistake of laying open a hernial tumour with a bistoury, when he intended only to open an inflamed and suppurating gland. The use of the exploring needle saves, I know, from many mistakes in obstetric Surgery; and since the safety with which it may be introduced into the most important organs and the most malignant tumours has been abundantly demonstrated, I think its employment might be advantageously extended. The best exploring needle is a long, slender, thread-like trocar, with a wire stylet passing through it. Of course there will be no escape of pus through it, when it has been thrust into a solid tumour or into an inflammatory swelling before pus has been fully formed, and even when pus is there, it is usually only a drop or two that escapes through the narrow tube. You will not find the pus in some cases traverse the trocar, particularly if the pus is thick, but on withdrawing the trocar and blowing through it, a drop or two will escape from the end of the trocar. But when none flows out, the negative sign is itself of importance. While, on the contrary, if a drop escapes it may be a sufficient warrant for you to proceed to the more free evacuation of the purulent collection. A Medical practitioner, of great ingenuity, who had been many years in India, when his health began to fail him, came home several years ago, and while spending a short time in Edinburgh, I had an opportunity of showing him some cases of pelvic cellulitis, where I succeeded in demonstrating the presence of pus by the use of the exploring-needle. Soon after going to London he met some Medical men there in consultation upon an old Indian patient of his. The case, as he afterwards told me, seemed to him to present the chief characteristics of the examples of pelvic abscess which he had seen here. He expressed to the Medical attendants of the lady his opinion of the case, and proposed as a means of settling the difficulty to introduce an exploring needle into the seat of the disease. The other doctors rather scoffed at the idea; but, as they were altogether at sea as to the nature of the disease, they agreed to allow him to introduce the exploring needle, which he accordingly did. To his great surprise and vexation, however, no escape of pus followed the withdrawal of the stylet; but, being still unconvinced that his opinion was erroneous, as a last resource he applied his mouth to the end of the tube, and succeeded, by sucking it, in extracting a few drops of pus sufficient to convince his sceptical brethren of the true nature of the case, and of the value of the exploring-needle as a means of diagnosis. He was then allowed to open the abscess, and the patient got speedily well. In consequence of his treatment of this case, my friend got rapidly

into a large practice in London, but after a few years his disease unfortunately returned, and death struck him down.

When, then, you have a patient attacked with rigors, followed by a high degree of fever, and attended with pain in the interior of the pelvis, and when, after a time, the fever changes in character, and instead of being inflammatory presents more of a hectic type, you may be pretty certain that she has been suffering from an attack of pelvic cellulitis which has passed on to suppuration. And in every case it will be possible for you to correct or confirm your diagnosis by means of a careful local examination. One or two marked symptoms may enable you sometimes to make a good guess as to the existence of the disease. Several years ago, I was attending with my friend Dr. Andrew Wood, an anxious case of labour, where the lady had manifested symptoms of insanity in the last periods of pregnancy. While thus engaged, a gentleman came, bearing with him a note to me from the North of England. The note was written by the Medical attendant upon the gentleman's wife, and anxiously desired me to visit the lady as soon as possible. In relation to her disease it stated only two bare facts, viz., that the lady who had been confined six weeks before, was hectic, and was suffering from great pain in the pelvis and down one of the limbs. I read the note to Dr. Wood, saying it was, I believed, a case of pelvic abscess, against the accuracy of which diagnosis he was inclined to wager. On visiting the patient in England next day I found a large pelvic abscess which I freely opened, and the patient made an excellent recovery.

Formerly, the changes produced by the disease caused it frequently to be confounded with cancerous, fibroid, or cystic tumours of the uterus and ovaries, or other organs of the pelvis; but now we may be almost always sure of the true nature of the case when we find the tumour associated with constitutional phenomena, running a regular and rapid course, and adhering to the bone or periosteum in the remarkable manner to which I have referred. For, let me repeat, inflammatory tumours feel fixed and immovable to a degree seen in the case of no other morbid growth, and more particularly when occurring in the broad ligament,—their most common seat—and lying close to the ilium, they feel so hard and adherent that they might almost be mistaken for an osseous tumour. The old stories of large ovarian and uterine tumours of a supposed nature yielding under mercury, etc. were in all probability merely tumours formed by inflammatory effusions of the kind I have been speaking of.

Before leaving the subject of diagnosis, I wish to mention one point more, that perhaps I ought to have alluded to earlier. We have already found that abscesses, the result of pelvic cellulitis, may ulcerate and discharge the pus which they contain by various channels. Internally, they may thus spontaneously open, 1, into the vagina; 2, into the cavity of the uterus; 3, into the rectum; 4, into some higher portion of the intestinal canal; 5, into the urinary bladder; and, 6, but happily very rarely, into the cavity of the peritoneum. The same abscesses may open externally at the umbilical region, in the hypogastric or iliac region, or they may burrow downwards and open at the top of the thigh, or pass through the posterior pelvic niches and open on the ilium or sacral region behind. I have seen once or twice the thin plate of the ala of the ilium apparently perforated by them. Their spontaneous opening in any of the internal mucous canals which I have named, is ascertained by watching diligently for, and tracing the escape of pus from these several canals. But I am anxious to impress upon you an additional fact. When an abscess is formed in the cellular tissue of the pelvis, it may discharge itself through more than one opening and in more than one direction; I have known abscesses thus open in the same person simultaneously or consecutively both on the cutaneous surface of the abdomen and into the bowel; both into the bowel and bladder; both into the rectum and vagina, &c. I have seen cases where in this way fistulæ have been established between the different points which I have named,—and between other points which did not seem at all likely to be in the course of them, as between the bowel and bladder, the intermediate genital canal having escaped. But when in any case after the pus has been evacuated these various openings remain and continue to furnish a purulent discharge, it often becomes a matter of importance to ascertain whether these fistulous orifices and canals communicate with each other, and whether the fluid that

escapes from them be derived from one common source; and I have not yet told you how you are to settle this question for yourselves. Sometimes it is ascertained by observing the contents of one canal escaping through another, or escaping externally, as fæces by a cutaneous or vaginal fistulous orifice. In a case which I alluded to a minute ago, of inter-communication between the intestinal canal and bladder, this course of the fistula was first ascertained by small appearances of feculent matter passing with the urine. But there are cases occasionally met with where you have not such peculiar discharges to guide you in your diagnosis,—as where the inter-communication is between the vagina and a cutaneous fistula, etc. How are you to ascertain the presence or absence of any inter-communication in such a complication? The first time that I ever had an opportunity of making a diagnosis as to this point was in the case of a patient who, after suffering for some years from the effects of pelvic cellulitis, was brought here from Holland to be under my care. She had three different openings—one in the vagina, a second in the thigh, and a third in the groin, all leading into the pelvis towards the side of the uterus, and all yielding a supply of pus. It became a question whether they all communicated with each other or not; and, although they seemed to converge, yet I could not succeed in passing a probe through one and bringing it out at the other, nor could I be sure that they met at any point until, on throwing a quantity of very much diluted tincture of iodine into the opening in the groin, I saw it come pouring out simultaneously into the vagina and through the opening in the thigh. By injecting, then, milk, or any coloured fluid, as a little weak tincture of iodine in this way into one of the openings in any case where a pelvic abscess has made its way to the surface in more than one direction, you will be able to determine whether these openings are connected with a common sinus, without subjecting your patient to the unnecessary pain of probing her; and, in addition to its extreme simplicity and ease of application, this means of diagnosis has the further advantage, let me tell you, of sometimes being a most effectual means of cure. It may be employed in cases of complex fistula in ano or fistula in vulva as well.

PROGNOSIS OF THE DISEASE.

Pelvic cellulitis is by no means a very fatal disease, however formidable it may be in appearance; and it proves, in the great majority of cases, very amenable to treatment. In many instances it may lead to no further result than the effusion of serum for a week or two, which causes much pain and distress at the time, but soon becomes absorbed, and leaves no bad effects behind. If coagulable lymph have been effused, the case becomes more tedious, and the patient may be long an invalid, and unable to walk; but ultimately you will succeed, or rather Nature will succeed, in most cases, in effecting its complete resorption. When pus has been developed and an abscess formed, its evacuation, whether spontaneous or artificial, is usually succeeded by a cure of the disease; but it is from the development of pus that the chief dangers attendant on the progress of pelvic cellulitis arise, for when an abscess has formed it may prove fatal in one of three different ways. Either, first, it may burst into the peritoneum and lead to a fatal peritonitis—an accident which, as I have already had occasion to explain to you, is a very rare occurrence indeed in connexion with pelvic cellulitis. Or, secondly, the cavity in which the pus was formed may not close up after the fluid has been evacuated, but may continue to give out a purulent discharge, and if these sinuses be of considerable extent, and the purulent secretion copious, the patient may be gradually worn out by the long-continued drain. But, thirdly, I have seen one or two cases where the disease, after subsiding for a time, again returned, and gradually became established in a chronic form, and where the patients eventually died of tubercular disease of the peritoneum—almost all cases, as you are aware, of chronic peritonitis being truly cases of tubercular peritonitis. No doubt these patients were constitutionally predisposed to the occurrence of tubercular disease, but there can be as little doubt that the localisation of it in the peritoneum was determined by the degree of irritation so long kept up in the pelvic cavity.

Pelvic cellulitis comparatively rarely destroys life; and if it does not go on to suppuration, it may not even afterwards affect the functions of the uterus. Menstruation is seldom

much, or at all events permanently influenced by it; but what I mean is, that the function of reproduction is not necessarily destroyed, especially when the disease is cut short in its first stages, and before suppuration supervenes. Many years ago, I received an impressive lesson on this point. Along with Drs. Abercrombie and Begbie I visited a lady who was suffering under an acute attack of pelvic cellulitis. There was a large and hard inflammatory effusion, which felt so very dense and firm when examined through the rectum that Dr. Abercrombie—and there never was a practitioner with a greater power and certainty of diagnosis—was inclined, after making a rectal examination, to declare the case one of a malignant or carcinomatous tumour. I had seen a sufficient number of cases by that time to be assured of the true and simply inflammatory nature of the malady, and I ventured to prognosticate a perfect recovery of our patient; but I added that she would have no more children after such an extensive pelvic effusion. She speedily recovered under the active antiphlogistic measures used by Dr. Begbie; but she did more—she afterwards became pregnant, and was delivered of twins.

In my next lecture I shall take occasion to point out how these dangers are to be avoided, and what should be the treatment generally in cases of pelvic cellulitis.

ORIGINAL COMMUNICATIONS.

SOME ACCOUNT OF DIPHTHERIA AND EPIDEMIC SORE-THROAT,

AS THEY HAVE PREVAILED IN THE PARISH OF ISLINGTON IN 1858-9.

By EDWARD BALLARD, M.D.

Late Lecturer on the Practice of Medicine at the Grosvenor-place School of Medicine; Medical Officer of Health for Islington.

Scope and Method of Inquiry.—The Medical Officers of Health in the metropolis are, by the courtesy of the Registrar-General, furnished every week with a copy of the mortality returns in their several districts. During the period embraced in this inquiry, I made it my business to investigate, as far as circumstances would permit me to do so, the conditions under which each case of fatal disease occurred, which was returned under the term Diphtheria or any other designation pointing to the fauces as primarily or secondarily the seat of the malady. The plan that I adopted was to obtain from the medical attendant an accurate statement of the date of origin, order of symptoms, and other facts of each case. At the same time, on visiting the house to ascertain the existence of any local cause, I took the opportunity of obtaining information upon such other points in relation to the origin of the affection, and the previous history of the patient as I desired. At the close of the first quarter of the present year, I found that I had a record embracing a greater or less number of particulars, of 80 cases, which I proceeded to tabulate. The results of this tabulation, together with some points of interest as regards some individual cases, are what I propose now to communicate.

Nature of tabulated cases.—Out of the 80 fatal cases there were 13 returned as cases of "Diphtheria" in which I failed to obtain any information beside what was briefly conveyed in the registrar's returns. These were for the most part the earlier cases in 1858. In all the other 67 instances I ascertained, among other matters the presence or absence of the peculiar exudations which characterise true diphtheria. In the following remarks I shall, therefore, classify the cases as follows, viz:—

Class 1.—Cases in which I have obtained satisfactory evidence of the presence of the true diphtheritic exudation upon the throat, or in which I saw it myself during life.

Class 2.—Cases which were certified as deaths from "Diphtheria" by the medical attendant, but in which I have obtained no particulars of the appearance in the throat.

Class 3.—Cases in which I was assured by the medical attendant that the exudation was absent.

These last-mentioned cases were returned as deaths from "Tonsillitis," "Quinsey," "Gangrenous Quinsey," "Inflammatory Sore-throat," "Gangrenous Sore-throat," and in one

instance as "Diphtheria." With respect to Class 2, it is important to observe, that whereas out of 58 deaths returned as from "Diphtheria," there were only 2 in which the exudation and other symptoms of the disease were ascertained on inquiry to have been absent, it is probable that of the 13 cases of which I failed to obtain full particulars, the majority, if not all, were really instances of the true disease. I refer to this, because it has been held by some that Medical Practitioners were applying the term "Diphtheria," loosely to all varieties of sore-throat that they observed during the course of the epidemic.

The numbers of each class stand thus:—

	Males.	Females.	Total.
Class 1	31	25	56
Class 2	4	9	13
Class 3	6	5	11
Total	41	39	80

By far the greater number of deaths from sore-throat, then, were of that class which presented the characteristic marks of true diphtheria. Of these the male deaths somewhat exceeded the female, the proportion of the two sexes is, however, brought nearly alike, if the cases of Class 2 are included.

Age.—The ages of the 80 persons varied from 16 days to 61 years. There were 5 infants who died under 1 year. They were aged respectively 16 days, 5 weeks, 8 months, and two were 9 months. All these were male children. There were 6 persons who died at ages above 20 years, and these were aged respectively 26, 29, 37, 49, and 61 years. All but one of these were females. The deaths were distributed among the ages thus:—

Age.	Under 1 year.	1 to 2	2 to 3	3 to 4	4 to 5	5 to 10	10 to 20	20 and upwards.
Class 1 ..	4	9	7	10	6	14	2	4
Class 2	2	2	1	1	4	2	1
Class 3 ..	1	1	2	2	..	1	3	1
Total ..	5	12	11	13	7	19	7	6

I do not presume to draw from this table any conclusion as to the liability of different ages to fatal attacks of this epidemic, for this I should have to compare the deaths with the number living at each age, but still the following conclusions may I think fairly be deduced from my cases:—1. That the disease was comparatively rarely fatal to infants in their first year. 2. That it has been chiefly fatal to children under 10 years of age. 3. That up to 10 years of age the greater number of fatal cases were in males, the numbers being 39 males and 28 females; and that in ages above 10 years the preponderance of fatal cases was in females, the numbers being 2 males and 11 females.

Symptoms and Progress of Diphtheria (Class 1).—I am unable to say in what proportion of cases premonitory symptoms were observed. In the larger number, if present, they appear to have been overlooked. In some, however, they were sufficiently marked for periods varying from a week to a day before the setting in of the throat affection. For the most part they consisted in an undefined sense of illness with lassitude or prostration of strength, headache, heaviness, and redness of the conjunctivæ. Patients in this condition were usually considered to have "taken cold." In some instances there were pains in the back, general muscular pain or pains, now and then severe, in the joints, as in the wrists and ankles. In three instances the early disturbance of the system was characterised by diarrhoea with or without vomiting. I have no question that in certain cases the disease breaks out without any warning.

The earliest symptom that attracted attention to the throat was usually a difficulty in swallowing, or "an unpleasant sensation in the throat." At this period if the exudation was not apparent the mucous membrane of the fauces was reddened, the colour being usually dusky or of a claret hue. The appetite was lost early, except in a few cases, where food was not refused until near the termination of the case. With these symptoms there was more or less pyrexia. The amount of the febrile reaction varied: in a few the rapid pulse observed at the first was also firm, but neither the firmness of pulse nor heat of skin lasted long, giving place in two or

three days at the longest to the weak and rapid pulse of the confirmed disease. Mostly the pulse was weak and atonic from the first appearance of the throat symptoms. In some cases the first symptom noticed was unusual hoarseness of the voice; in a few the swelling of the tissues about the base and angles of the jaws first attracted notice; and in three instances the disease was ushered in by a very remarkable drowsiness, the child sleeping nearly all the first day of the illness.

The Symptoms of the Confirmed Disease were generally these—*Difficulty in swallowing*, especially solids,—difficulty, I believe, rather than pain; although in some cases the pain in swallowing was marked, and, as in tonsillitis, extended to the ears. This difficulty conspiring with the febrile anorexia, led the patients to *refuse food* from an early period of the attack. It was commonly observed that liquid food, wine, and medicines, which would not be swallowed when offered by the attendants, were taken pretty readily when the medical man administered them himself. It now and then happened that although the other characteristic features of the disease were present, liquid food was accepted whenever offered, and swallowed, apparently without difficulty throughout. The *exudation* varied in the seat of its earliest appearances: sometimes it was first seen upon the tonsils, uvula, or soft palate, at others on the pharynx, inside of the cheeks or lips or upon the dorsum of the tongue. Sometimes, when first seen, it was in the form of little roundish patches of the size of a split pea, which, sooner or later, coalesced; or when first noticed it was spread continuously over the parts affected. Its colour was white, cream-coloured, ashy, and sometimes more or less dark brown, from admixture of blood corpuscles; when removed, the membrane beneath was dark coloured and pretty sure to bleed. With all this the membranes and tissues beneath were, with the tonsils, more or less swollen. Sooner or later the breath became offensive, so much so occasionally as to constitute a "horrible fœtor," perceptible on entering the room. I am assured that in some of these cases, although I have seen no such instance myself, there was absolute death of some of the tissues, and in one the entire uvula disappeared by this process. There was usually disfigurement by swelling of the tissues beneath the angle or base of the jaw: the swelling was hard to the touch in all the cases that I saw, and sometimes the skin in this situation was ecchymosed. In the greater number of cases the voice became first husky, and at last was altogether lost, the patient being unable to speak, except in a whisper; but in some the voice, although altered, did not altogether disappear. Croupy breathing and cough were also by no means constant phenomena, in some cases they were wanting throughout; in two or three instances the fibrinous casts of the upper air passages were coughed up with decided temporary relief to the dyspnoea. Where the laryngeal symptoms were severe there was the customary restlessness with turbulence of the features. Sometimes the attempt to swallow was followed by a return of the food through the nose. In many of the advanced cases there was a discharge of bloody mucus or ichor from the nares. The general condition of the patient in this confirmed stage of the diphtheria was invariably one of prostration: the pulse was small and rapid, and there was a tendency to coldness of the extremities, which in cases verging upon asphyxia became cold and blue. In five cases there were purpurous spots noticed upon the trunk, neck, or extremities; in one of them so long as ten days before death, but in the others either on the day of death or the day preceding. In four instances there was more or less severe epistaxis; in one of these it appeared to relieve a violent headache accompanied with delirium; in the others, coming on later in the case, it as evidently hastened the death by the exhaustion it occasioned. The intellect usually remained clear to the last, but in some the final exhaustion was accompanied by delirium and coma.

Duration of the Disease.—In only two cases did I fail to ascertain this point, which is represented in the following table:—

Days	1	2	3	4	5	6	7	8 to 14	15 to 21	22 to 28
Class 1	1	7	4	6	5	5	18	6	4
Class 2	1	1	1	1	2	1	2	3
Class 3	3	..	1	1	4	1	..
Total	1	2	8	8	8	7	8	25	7	4

The sex and age of the patients exercised little or no influence over the duration of these fatal cases. In the instance of four infants under one year, however, included in Class 1, the mean duration was four days. At each of the other ages, the mean duration was from nine to eleven days.

Mode of Death.—In 59 of the cases that I inquired into, the mode of death was stated by the Medical attendant as follows:—

	Class 1.	Class 2.	Class 3.	Total.
From extension of the disease to the larynx, œdema of the glottis, or asphyxia	22	..	5	27
Sudden	4	..	1	5
From exhaustion	20	1	2	23
„ disease of brain	1	1
„ convulsions	1	1	2
„ suppression of urine and dropsy	1	1
Total	48	2	9	59

These numbers will also assist in determining the periods of the disease at which these several modes of death are imminent. The following table embraces 58 cases:—

	1st week.				2nd week.				3rd week.	4th wk.
	Laryngeal complication.	Sudden.	Exhaustion.	Brain disease.	Convulsions.	Laryngeal complication.	Exhaustion.	Convulsions.	Suppression of urine.	Exhaustion.
Class 1	15	2	7	1	..	7	7	..	1	2
Class 2	1
Class 3	3	1	1	1	1
Total	18	3	7	1	1	8	8	1	1	3

The danger from which a fatal result is mainly to be apprehended in the course of the first week of the disease is extension of the latter to the upper part of the air-passages, and consequent asphyxia. The sudden deaths in this week are probably due to the same cause, giving rise to spasmodic closure of the glottis. As the malady advances into the second week, the chances of death from this cause are only equal to those from the general prostration of the vital powers. In the third and fourth weeks, the latter is the condition mostly to be dreaded; the sudden deaths at this time being probably due to syncope. They have occurred during some muscular effort, the patient falling back dead into the nurse's arms.

The following table is constructed to show the mode of death in 59 patients of various ages:—

	Ages.											
	Under 5 years.				5 to 9 years.			10 to 19 years.			20 yrs. & upw.	
	Laryngeal complication.	Sudden.	Exhaustion.	Convulsions.	Laryngeal complication.	Exhaustion.	Suppressed urine.	Laryngeal complication.	Sudden.	Exhaustion.	Laryngeal complication.	Exhaustion.
Class 1 ...	14	4	12	..	7	4	1	2	1	2
Class 2	1
Class 3 ...	3	..	1	1	1	..	1
Total...	17	4	13	2	7	5	1	1	1	3	2	1

The following represents the frequency with which the disease in the 80 cases is stated to have occurred primarily or secondarily to other maladies. But I attach little weight to these numbers, since the certificates of death furnished to the Registrars by Medical men do not always state whether the disease of which a patient dies is primary or secondary. In

the main, however, this table is tolerably correct so far as my inquiries proceeded, that is, in respect of classes 1 and 3:—

	Primary.	Secondary to				
		Scarlatina.	Measles.	Whooping-cough.	Group.	Influenza.
Class 1 ...	47	5	2	1	..	1
Class 2 ...	9	1	1	1	1	..
Class 3 ...	10	1
Total...	66	6	3	3	1	1

Social Position of the Patients.—An opinion has prevailed, that while fatal maladies of the zymotic class have selected their victims generally from the lower ranks of life, diphtheria and epidemic sore-throat have prevailed more among the middle and comfortable classes of our population. In order, as far as my means permit, to put this idea to the test of numbers, I propose to divide the population into two groups:—1. *A superior group*, residing in streets the houses of which I know are occupied by single families in easy circumstances; and, 2. *An inferior group*, residing in streets occupied mainly by labouring men and their families, or the houses in which I know to be let out in single rooms or tenements. The following is the result of a distribution of the 80 cases on this plan:—

	Class 1.	Class 2.	Class 3.	Total.	Mean mortality of three years in streets, etc., where these deaths occurred.	Per-centage of deaths from diphtheria and epidemic sore-throat.
Superior group	36	7	7	50	142	35.2
Inferior group	20	6	4	30	124	24.2

The above proportion is preserved if merely the true and reputed deaths from diphtheria are compared with the mean mortality of the streets in which they occurred, the number then being for the superior group 32.8 per cent., and for the inferior, 21.6 per cent. Taking the class 1 alone, the proportion is for the superior group 32.1 per cent., and for the inferior, 23.5. Thus the fatality of epidemic sore-throat and diphtheria appears to have been half again as great in the middle as in the lower ranks of society, when a comparison is made with the mortality arising out of diseases of all kinds. The absolute frequency of the fatal attacks could only be determined by such an enumeration of the population of the several streets as I do not possess.

Let me contrast this result with that which I found in respect of zymotic diseases of all kinds as included in the list adopted by the Registrar-General. The following table represents the number of deaths in three years in 109 streets inhabited by persons of the superior, and 150 by persons of the inferior class:—

	Number of streets.	Total deaths in 3 years.	Deaths from disease of zymotic class.	Per cent. of all deaths.
Superior group	109	734	133	18.1
Inferior group	150	2237	687	30.7

Here the inferior group is that which exhibits the zymotic mortality in excess, a result in accordance with universal experience.

(To be continued.)

CASES OF ACUTE NECROSIS FOLLOWED BY PYÆMIA.

By WILLIAM H. STONE, M.B. Oxon, L.R.C.P.
Medical Registrar to St. Thomas's Hospital.

THREE cases have been admitted into St. Thomas's Hospital, under the care of Dr. Gooldeen, within a few months, which present some features of interest.

All of them have consisted essentially of very rapid and acute necrosis of a large bone. All have terminated fatally within a short time from pyæmia, secondary on the local disease.

The general symptoms in all were such as would naturally mislead the observer. Indeed this was so remarkably the

case, that although all were, strictly speaking, Surgical cases, one was actually transferred from a Surgeon's ward to the care of the Physician, as being a case of typhoid fever; the other two were assigned to the Physician, treated and considered as acute rheumatism.

Careful post-mortem examinations were made in every case. These are important, not only as throwing much light on the pathological history of both the local and the general disease; but, taken in conjunction with the symptoms during life, as offering valuable indications for the diagnosis and treatment of other similar cases.

Lastly, it is not impossible that some of the obscure cases of pyæmia on record may have originated in some such local lesion as this, which has remained undetected. Dr. Bristowe is of opinion that there are reports of autopsies made during former years at St. Thomas's Hospital, which very much favour such a supposition.

Case 1.—M. A., aged 15, servant. Admitted December 18, 1858. A well-developed girl, of healthy aspect. Stated that she had always enjoyed good health previously to this illness. Had never had acute rheumatism, or other serious disease. The catamenia had only recently made their appearance, but were not in any way abnormal. Seems to have been in a good place, and not subject to any privation. Was well and at work until five days before her admission. At that date (December 13) she began to suffer from severe pain in the left forearm, especially on its posterior aspect. Some swelling appeared in the course of the day. Her general health does not seem to have been materially affected until the following morning (December 14). On that day she had a severe rigor, accompanied by vomiting, headache, pain in the chest, and cough. She took to her bed, and became rapidly worse, complaining of the same symptoms, with delirium for the last night or two.

On admission, the general aspect was that of a case of acute rheumatism, with cardiac complication. As such it was taken in. It was not, however, thought possible, or desirable, to make a minute examination in the taking-in room. When seen in the ward, she was manifestly suffering from extensive and severe disease. The face was anxious and pale; the manner confused, and only partially conscious; although loud questions were rationally answered. Pulse 130, but only counted with difficulty from its feebleness. Respiration 44 per minute, accompanied with a moan. Skin cool, and not perspiring. Some ineffectual cough, and apparent inability to expectorate.

On examining the chest, loud rhonchus with large moist crepitation was audible in every part; and could also be felt as a thrill conveyed to the fingers. In an interval of respiration, the heart could be heard beating feebly, but with normal sound. There was no abnormal dulness, and no great tenderness of surface. The left arm and forearm were swelled and tense, rather red, and somewhat tender, though not acutely so. All the articular movements were easily performed, and without pain. Neither the wrist nor elbow-joints bore traces of rheumatic inflammation. The swelling was greatest in the middle and upper thirds of the forearm; of a doughy feel, giving no evidence of fluctuation. The hand was not at all implicated. Wine and a stimulant mixture were given; but she sank the same evening, without alteration of symptoms.

On post-mortem examination, forty-two hours after death, the following morbid appearances were found:—

The left arm was much swelled, and rather hard, with patches of redness. The lower third of the radius, exclusive of the epiphysis, was denuded in nearly the whole of its extent, and surrounded by thick pus, which infiltrated the cellular and muscular tissue in the neighbourhood. On making a section of the bone, its interior presented no unhealthy appearance. The muscular substance of the arm was generally healthy; but most of the superficial and muscular veins were filled with imperfectly-formed clots and puriform fluid. The wrist-joint and radial epiphysis were perfectly healthy, as was also the ulna. The brain was considerably congested, but otherwise healthy. Both lungs were slightly attached to the parietes by a layer of recent lymph. This was unequally deposited in patches, and much more abundant on the left than on the right side. The lungs were of ordinary size, and for the most part crepitant. They presented numerous patches of pulmonary apoplexy, from the size of a filbert downwards, irregularly scattered from apex to base. Some of them were a little decolorised at the margin,

and the small branches of the pulmonary artery connected with most if not all of them were distended with adherent decolorised clot, mixed, in some cases, with a little pus-like fluid. A few distinct abscesses, from the size of a horsebean downwards, were scattered here and there.

The bronchial tubes contained a large quantity of frothy fluid. The pericardium was lined by recent lymph. It was more abundant on the surface of the heart than on the parietal layer, and was chiefly aggregated on the left side. The heart was of ordinary size, and firmly contracted. Its surface presented beneath the false membranes numerous spotty and mottled patches of intense congestion and extravasation; and on making sections of the organ, many abscesses, from the size of a pea downwards, in various stages of formation, were found in the substance of the muscular parietes. The valves were healthy; the cavities contained a little partially decolorised coagulum. Peritoneum healthy. Liver of usual size, for the most part healthy. The surface presented several irregular pallid patches, surrounded by a broad congested margin. On section, these patches were found to be composed of blocks of tissue presenting similar characters, and extending some little distance into the organ. Spleen, pancreas, stomach, intestines, and suprarenal capsules healthy. The kidneys presented a considerable number of minute abscesses surrounded by congestion, but the organs were otherwise healthy. On microscopic examination of the fluid in the pulmonary branches, it was found to consist chiefly of distinct pus cells, but in some instances of granular matter and debris of coagulated fibrine.

Case 2.—M. H., aged 29, servant, admitted November 24, 1858. A robust healthy woman, above the middle height, was stated to be suffering from rheumatism, and taken into a Medical ward in consequence. It appeared she had been out of health for a fortnight, and that before that time she had been suffering from mental anxiety and some privation. She had, however, been able to do her duties as household servant until a week before admission. She had at first complained of severe pain in the right thigh, which had soon after become swelled and tender. Two days before admission there had been some aggravation of the symptoms, but without any change in character. When taken in she had the aspect of a person suffering from acute rheumatism, with considerable febrile symptoms. She was quite sensible, and complained most of pain in the right thigh. On examination, this was found to be swelled and puffy, of a doughy feel, and very tender. It could not be discovered whether the knee-joint was implicated, from the great œdema and tenderness. There was no circumscribed redness or fluctuation in any part. An anti-rheumatic treatment was adopted.

On the following day (25th) she was much worse. After a severe rigor, she became violently delirious, throwing the bed-clothes off her, and making much noise.

On the morning of the 26th, the delirium gave way to signs of collapse. These were accompanied by sudden and violent bronchitic symptoms; moist crepitation, both large and small, became audible in all parts of the chest, and could be distinctly heard when standing at the bedside. The face became livid and suffused; the respiration very rapid; pulse insensible at the wrist. She was able to speak sensibly and firmly until a few minutes before her death, which took place at noon of this day.

On post-mortem examination, twenty-four hours after death, the appearances were as follow:—

The right thigh appeared unusually plump. On cutting down to the bone a large quantity of thin pus escaped. The femur, in the lower two-thirds of its shaft, was to a great extent denuded, and bathed in pus. The muscular tissue around was softened and infiltrated with pus. Many of the veins of the muscle were distended with coagulum, partly recent, partly buff-coloured and adherent; they contained in many places thick sanious puriform fluid. The bone was not completely denuded, for here and there soft shreddy muscular fibres were still attached to its surface; and in one oval patch, about two inches long and one inch broad, was a softish granular deposit of recent bone, thin at the margins, increasing in thickness towards the centre, and at the latter point presenting a circular orifice about a quarter of an inch in diameter, the bottom of which was formed by denuded shaft.

The joint and epiphysis were healthy. On making a vertical section of the shaft, the greater part of the medullary cavity

was found to be occupied by soft lymph, puriform fluid, and coagulum.

The larger vessels of the thigh and their contents seemed healthy.

There was a shallow commencing bed sore over the sacrum.

Brain congested, with some increase of serum on its surface; otherwise healthy.

Pericardium and heart healthy.

The pleuræ were for the most part healthy, and free from old adhesions. The surface of both lungs, however, presented two or three largish, exceedingly thin, and scarcely visible patches of recently deposited lymph. Each of these was found to radiate from a central spot, in which the subjacent lung was elevated, and of a black colour. On section, the black spots were found to be distinct apoplectic masses, from the size of half a marble downwards. There were about six in the left, and three or four in the right lung. All were clearly and wholly apoplectic; none was of the nature of an abscess, though one or two presented an imperfect buff-coloured margin. In addition to these, were some black elevated patches of extravasation into the sub-pleural tissue. The lungs were congested and oedematous, but crepitant. The bronchial tubes contained a good deal of secretion, and were somewhat congested.

Peritoneum healthy. The liver was of usual size, and for the most part healthy; its surface presented several irregular mottled patches of various sizes, which had a distinct port-wine colour, together with several tracts of remarkable pallor. The congested condition was quite superficial; the pallid extended some little distance into the substance of the organ. Spleen, stomach, pancreas, intestines and suprarenal capsules healthy. The kidneys were for the most part healthy; the right was very large, and presented a group of indistinct abscesses, altogether about as large as a hazel-nut; the suppurating part formed an irregular cylinder in the cortex, consisting of a number of smaller imperfect cylinders of suppuration, separate from each other and surrounded by congested margins. On separating the capsule from the diseased tract, the small abscesses abutting on the surface were laid open.

(To be continued.)

METHOD BY WHICH

THE ACUTE PAIN OF GLAUCOMA WAS REMOVED BY OPERATION.

By HAYNES WALTON, F.R.C.S.

Surgeon to St. Mary's, and to the Central London Ophthalmic Hospitals.

THE treatment of glaucoma by surgical operation still occupies the attention of Surgeons; and there are marked differences of opinion respecting the curative benefits of Græfe's iridectomy, or excision of a piece of the iris. But this is a question I shall not enter into. It is about the acute pain alone in the later stage of the disease, when the eye is already spoiled, that I intend to say a few words.

A female, in middle age, was sent to me in private by Mr. Wall, of Paddington, with acute glaucoma of the left eye, which was very tense, much injected, the pupil dilated, and the iris pressed forwards by the semi-opaque lens. Vision was quite lost; and I was consulted solely on account of the severe suffering, sometimes lasting for several consecutive hours, but more generally in paroxysms, which nothing has been able to subdue. The extreme vascularity of the eyeball, and the general plethora, induced me to order cupping to the temple, and purgatives. Not the slightest benefit ensued. Opium, both locally and generally, were then tried, with no more effect than securing better nights' rest than hitherto, but the general health was deranged by the narcotics, which were discontinued. Other drugs were administered in vain. Thus, after a period of five months, the patient got no material benefit either from myself or from any other Surgeon by whom she had been treated, and she had applied to several. She expressed her desire to submit to any operation likely to afford relief, and she was the more anxious as the right eye was certainly sympathetically affected, as manifested by intolerance to light and lachrymation. Rather than extirpate the eyeball, a practice that my patient had heard of, and which is certainly very objectionable if it can be avoided, or

rather than reduce it by the removal of the anterior portion, an operation that is very serviceable in checking certain morbid actions, and which should when applicable be preferred to the above, I determined to try the experiment of extracting the opaque lens, and evacuating some of the vitreous humor. I effected this without wounding the iris. The vitreous humor was apparently quite normal.

The acute pain ceased, and there was less uneasiness during the healing process, which was quickly effected, than is often experienced in successful operations for the extraction of the cataract. It is just five weeks since I operated. There has been no recurrence of pain; there is yet conjunctival vascularity; there is no other abnormal appearance about the eye, except that the pupil is irregular, a part of it being adherent to the corneal wound, but there is no prolapse. The right eye has lost the sympathetic irritation.

I desire not to set more value on a single example like the present than it is worth, nor do I attempt to generalise from a single instance; but even as a unit, as an isolated fact, it has its value. It will encourage me to investigate the matter further, and I doubt not that with this publicity the subject will receive attention from others. I shall not attempt to explain the rationale of the operation, nor do I venture to speculate on any advantages that may be gained by this means when adopted in the earlier stage of the disease. My object is to record an experimental success in the removal, by a simple plan, of a distressing symptom that will not at all times succumb to any ordinary treatment, except that which mutilates or disfigures. I can affirm, from personal experience, that Græfe's iridectomy does fail in these instances.

The tendency to internal hæmorrhage, when a diseased eyeball is incised, is well known; and I adopted the generally successful preventive of applying a pledget of cotton wool and a bandage over the eye, and retaining it two or three days. No bleeding occurred.

69, Brook-street, Hanover-square.

THE LONDON

PRACTICE OF MEDICINE AND SURGERY.

ST. BARTHOLOMEW'S HOSPITAL.

FISTULOUS CHANNEL THROUGH THE TIBIA.—OPERATION.

(Under the care of Mr. STANLEY.)

If in a case of compound fracture of the leg, there should still remain, at the date of more than a year after the injury, a fistula passing down to bone, the ordinary inference would be that some fragment had necrosed and was keeping up irritation. That such however need not necessarily be the fact was demonstrated the other day, in the case of a patient under Mr. Stanley's care in St. Bartholomew's. A man of about 25, in fair health, received a compound fracture of his right leg eighteen months ago. He had the usual treatment for that accident, and good union without deformity ensued. Two sinuses, however, remained, the one on a higher plane and to the inner side of the other, and both about two hands breadth above the ankle, in the front of the leg. By either of these the bone might be reached. There was no material swelling about the part. Loose bone had never been detected. A fortnight ago, Mr. Stanley, assisted by Mr. Paget, proceeded to explore the part in the hope of finding some fragment which might be removed. By free incisions the two sinuses were laid into one, and the surface of the tibia exposed. It was now found that a probe could be passed quite through the shaft of the bone from an opening on its inner surface to another lower down in its outer aspect. With bone-pliers, the overlying bridge of bone was cut away, and the osseous fistula laid open. After the most careful search, no exfoliated fragment could be discovered, and the bone wherever exposed was healthy and well supplied with vessels. The track of the fistula was lined by granulations.

Mr. Stanley commented at the conclusion of the operation on the peculiarity of the case. Although undoubtedly rare instances of fistulæ passing through bones and obstinately refusing to heal until laid open had been met with before, and he had seen cases like the present in which no evidences of

diseased action going on in the osseous structure could be detected. The only plan was to treat them as you would a fistula in soft parts and lay them freely open. It was impossible to tell before hand that no necrosed fragment was present, and the most careful search ought, therefore, always to be made. The Surgeon ought not, however, to feel disappointed on not finding any, but should rest satisfied that the measure adopted has been the best for his patient.

The man in this instance has done very well since the operation; the wound is healthy and likely to heal quickly. No exfoliation of bone has since occurred.

DISEASED HIP AND KNEE IN OPPOSITE LIMBS.— ANCHYLOSIS OF HIP IN BAD POSITION.— FRACTURE.—EXCELLENT RESULT.

(Under the care of Mr. STANLEY.)

There is, in one of Mr. Stanley's wards, a little boy whose case, besides exemplifying the occurrence of destructive disease of the hip on one side, and a like affection of the knee on the other, has presented several distinct phases of great practical interest. He has been in the Hospital nearly two years, and is now convalescent in a far better condition as regards power of walking than could at one time have been expected. Originally, he came under care two years and a half ago at another Hospital, with what appeared to be a large abscess in the left thigh, unconnected with either hip or spine. At any rate, as regards the freedom from disease of the latter regions, he could run about as well as ever, had no pain in back or hip, and presented not the slightest deformity. He was at that time a fair-complexioned boy of five years old, with blue eyes, and beautifully soft flaxen hair. His mother at the time was the subject of phthisis, from which she has since died. The abscess threatening to burst, was punctured, about the middle of the front of the thigh, and nearly a pint of matter was evacuated. For a fortnight after this, he continued to walk about, and had no material pain in the part, when suddenly the symptoms of acute inflammation of the joint developed themselves, and he became confined to bed. Most profuse suppuration followed, and he sank into a condition of extreme hectic. The limb now became thrown outwards, and when, two months from the commencement, he was put under chloroform, in order to have the thigh brought down and a straight splint applied, there were evidences that the head of the bone was destroyed. He could not bear the splint, and his life being despaired of, it was removed, and the limb, supported on pillows, allowed to rest in any position most comfortable. The upshot of this was, that it became fixed almost at right angles with the pelvis, sticking out away from the trunk.

During the greater part of the period above alluded to, the boy was at his own home, and was not under the regular treatment of any medical man. We have obtained the above particulars from a Surgeon who saw him occasionally, and at long intervals. When admitted under Mr. Stanley's care, the state of his left limb was as described. He was reduced to the last degree of emaciation; as near an approach to an *anatomie vivante* as could well be imagined, and his right knee was stiff from long disuse. After some months' constitutional treatment, which resulted in much improvement, Mr. Stanley determined to make an attempt to bring the limb into a better position, and here begins the second stage of interest in the case.

The boy being under the influence of chloroform, it was endeavoured by force to bring the thigh down, but the ankylosis was found to be so firm, that this was impossible. Suddenly, however, in an effort at bending, a crack occurred, and it was evident, from the altered condition of things, that the neck of the bone had fractured. Availing himself of this occurrence, Mr. Stanley brought the limb down straight, and applied a splint to keep it there.

A stranger seeing the boy now (July, 1859; more than a year subsequent to the artificial fracture of the bone) for the first time, would not notice that anything was amiss with his left limb. It is quite straight, well placed under the trunk, and the boy can bear full weight on it, and use it freely. So much for the very successful result of the bold practice pursued. Unfortunately, however, while surgical science has been doing so much for the ankylosed hip, a complication has been developed in the form of acute and destructive inflammation of the opposite knee. The disease, in this instance, ran a very similar course to that which the preceding attack in the hip did, being attended by profuse

suppuration and rapid disorganisation. It is now in abeyance, but the boy, although about the ward, still has splints, &c., about his knee, and his right is much the worse limb of the two. There is no motion in the left hip, but the pelvis moves so freely with the limb, that this is scarcely noticed.

CASE OF POPLITEAL ANEURISM TREATED BY THE NEW FLEXION METHOD.

The case of popliteal aneurism under Mr. Paget's care, to which we alluded in a recent number, has since been treated by ligature of the femoral artery. It will be recollected that much swelling and irritation about the sac had followed a trial of the flexion plan. At the time of the application of the ligature, Mr. Paget did not consider that the aneurism had become diffused; but about this he stated there was some doubt. The man has done exceedingly well ever since; and although the operation was only on Tuesday week last, the ligature has already come away. The aneurism is solidifying, and diminishing in size.

GUY'S HOSPITAL.

FOREIGN BODY IN THE TRACHEA—TRACHE- OTOMY—DEATH—AUTOPSY.

(Under the care of Mr. COOPER FORSTER.)

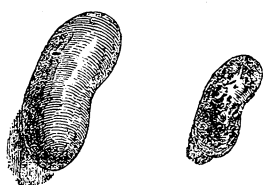

EARLY in the morning of June 6, a little boy, aged 3, was brought to Guy's Hospital, with the following history. At two o'clock on the day before while playing with a French bean he put it into his mouth, and soon afterwards suddenly became choked. He coughed, struggled violently, and became livid in the face. His father snatched him up and hurried with him to the nearest Surgeon. On his way he suddenly became relieved. Some medicine was ordered, and the danger being considered over, he was taken home again. Gradually during the evening difficulty of breathing developed itself, and he passed a restless night. Towards morning the dyspnoea and restlessness had become aggravated, and at eight a.m. he was taken to Guy's Hospital.

Mr. Cooper Forster saw the boy very soon after his admission, and found him with livid lips, gasping for breath, and showing all the signs of urgent thoracic distress. On auscultation no respiratory murmur could be heard in the right side of the chest, the right lung appearing to be quite impervious to air. With the exception of the first paroxysm, there had been no cough throughout. Mr. Forster stated that he felt no doubt that the bean was lodged in the right bronchus. To this conclusion, the history of the case and the symptoms present alike pointed. There had been at first the indications of impaction of the bean in the larynx, after this a lull had followed, and now there was positive evidence that some obstruction existed to the passage of air into the right lung. Was there any reasonable probability that the child would get rid of the bean *per vias naturales*? Our readers will, we think, be unanimously with us in answering this question in the negative, regard being had to the size of the larynx in so young a child, and to the dimensions of the intruding body, as accurately represented in the sketch below. Practically, however, the imminent and rapidly increasing danger to the child's life put this question quite aside. The dyspnoea was fast increasing, the veins of the neck were already turgid and prominent, and, unless relief could be afforded by operation, it was clear that the child must sink. Under these circumstances, Mr. Forster at once performed tracheotomy. No chloroform was given. The neck was unusually thick and fat. The veins which were divided in the incisions bled most profusely, and two of them required ligatures before the operation could be proceeded with. On reaching the trachea, Mr. Forster intentionally made the slit in it much longer than usual. The child's dyspnoea appeared to have been much relieved by the loss of blood, and when the operation was completed, he seemed much more comfortable than before. Attempts were first made to excite cough, in the hope that the bean would be expelled, but these failed. The child was now laid on its chest, and struck sharply on the back, and subsequently he was also held for a time with the head downwards, the strokes on the back being repeated in that position. All efforts to effect the dislodgment of the bean proved, however, fruitless, and were at length, of necessity, desisted from.

On the day following the operation the child was feverish.

Mr. Forster attempted, by the introduction of a pair of long curved forceps, which had been procured for the purpose, to seize the bean, but could not succeed in doing so.

On the 8th inst. at six in the evening, the child, who had been getting gradually worse, died.

At the autopsy the bean was found firmly plugged into the right bronchus. Its size is represented in the appended cut. It closed the orifice of the bronchus much as a cork might have done, and projected out into the trachea above. The right lung was collapsed and solid, but had no traces of inflammation.

It will be seen that the bean had swollen by the moisture of the part, until it might well be supposed to fix itself very firmly in the bronchial tube. At first it had no doubt acted the part of a ball valve, and while allowing the air to escape upwards, prevented its ingress. Its rounded exterior would make it almost impossible for it to have been grasped effectually by forceps. There was no reason whatever to think that the child's death had been hastened by the operation; on the other hand, indeed, so far as it went, it decidedly seemed to relieve the breathing, although, from the peculiar character of the foreign body, it was ineffectual in the accomplishment of the main intention. The left hand figure shows the bean of the size to which it had swollen, and the other that of a similar bean while dry.

SAMARITAN HOSPITAL.

THREE CASES OF OVARIOTOMY.

(Under the care of Mr. SPENCER WELLS.)

(Concluded from page 33.)

Case 3. MULTILOCULAR OVARIAN CYST—OVARIOTOMY—RECOVERY.

[From Notes by Mr. PHILLIPS, House Surgeon.]

J. F. aged 29, lady's-maid, single; admitted under Mr. Spencer Wells, May 17, 1859.

History.—Has been in good health until eighteen months ago, when she first noticed a hard swelling on the right side. This increased, and Mr. Burton, of Blackheath, diagnosed ovarian disease. Increase continued, and she was admitted into St. George's Hospital, under Dr. Lee, in August, 1858. She remained there ten weeks, and left with directions to return when tapping became necessary. The catamenia continued regular up to November; since then they have appeared every fortnight. She was re-admitted to St. George's on the 1st of March, 1859. She was tapped, and 31 pounds of thick amber-coloured fluid removed. After three weeks she went to the country, where she remained for six weeks previous to her admission to the Samaritan Hospital.

State on admission.—A well-formed, middle-sized, rather delicate-looking person. The abdomen is greatly distended, measuring 41 inches in circumference at the umbilicus, and 19½ inches from ensiform cartilage to symphysis pubis. She suffers great pain from the distension, and from indigestion. The respiration is much impeded; fluctuation very distinct all over abdomen; dullness on percussion anteriorly and laterally, but clearness in right lateral lumbar region; both lumbar regions, and left lateral lumbar, dull; anterior wall of vagina depressed; uterus normal and moveable, but pressed backwards; pulse rapid and feeble; thoracic organs healthy.

Progress of the case.—May 18.—Has passed a very bad night, suffering from distension; but some relief was obtained by opiates and a purgative.

May 20.—It was decided in consultation that Mr. Wells should tap, and if the cyst proved to be unilocular, inject iodine; while, if it were multilocular he should perform ovariectomy if her general health improved, and before the cyst became so much distended again. Accordingly, he removed 23 pounds of viscid fluid, sp. gr. 10.12, and by the use of Dr. Hewitt's ovarian sound, satisfied himself that there was a cluster of smaller cysts within the principal one. Iodine, therefore, was not used. Some temporary relief was ob-

tained by the tapping, and she left the Hospital May 27 with directions to return when the girth reached thirty-six inches.

She was re-admitted June 22, 1859, in much better health than before, and it was decided after consultation that Mr. Wells should remove the cyst.

24th.—Chloroform was administered by Dr. Graham Weir, of Edinburgh. Present, the staff, Dr. Fyfe, Mr. Evans, of Torquay, Mr. Cumberbatch, etc. Mr. Wells made an incision, four inches long, over the linea alba, midway between umbilicus and symphysis pubis, dividing the tissues until the cyst was exposed. He then broke down some extensive but very slight adhesions to the parietes first with the finger and then with the hand, and rapidly emptied the principal cyst by a large trocar. Some traction was made on this cyst as it was being emptied, but it could not be withdrawn. A second interior cyst was then tapped and emptied, but the cyst still remained firm. Mr. Wells accordingly enlarged the incision until it extended from the umbilicus to about an inch from the symphysis pubis, and after separating a large portion of omentum which adhered to the upper portion of the cyst, and a coil of intestines, the cyst was withdrawn, and the edges of the wound carefully pressed together to prevent protrusion of the intestines. The peduncle was short and very broad, but after separating some portions of it which did not contain vessels, by the hand, it was secured by a clamp fastened close to the uterus, and the cyst cut away, leaving a portion projecting beyond the clamp. Considerable traction was necessary to keep the clamp outside the wound: but this was effected, and the divided edges of the abdominal parietes, including the peritoneum, united by harelip pins and by intermediate superficial wire sutures. The opposite ovary had been examined and found healthy.

The tumour consisted of one large cyst, and a group of smaller ones containing fluid of very different density. One contained almost pure blood.

She remained depressed for about two hours, when she became restless and complained of intense pain all over the abdomen. A large linseed poultice, covered with linen so that it could be changed easily, was applied very hot over the whole abdomen, and an enema of thirty minims of laudanum given in two ounces of water. This gave great relief. Sickness continued troublesome, but she passed a tolerable night.

It is needless to give a daily report of the case further, as it was almost one of uninterrupted recovery. The opium enema was repeated occasionally when there was pain. The poultices were used constantly for several days. On the third day she suffered a good deal from flatus, which was relieved by an injection of turpentine and assafoetida in thin arrowroot, a copious motion following it. Mr. Wells removed the pins on the fourth day. On the fifth the catamenia appeared unexpectedly. On the sixth day she appeared rather low and feverish, and the pulse became feeble and rose to 110. Mr. Wells carefully examined the wound, and pressed out from one to two drachms of very foetid pus from the track of one of the pins. This gave almost immediate relief. Sickness continued troublesome at times during the first week. The clamp was removed July 2, and the last of the superficial sutures on the following day. A fortnight after the operation she was sitting up in bed, eating and sleeping well, almost free from pain, pulse 80, and the wound quite healed, except at the spot where the peduncle had passed. Here there was still a little foetid purulent discharge.

July 14.—Wound healed; convalescent. She is to leave the Hospital in a few days.

Remarks.—The chief differences in the treatment of this case to those previously reported, were the use of very hot linseed poultices to the abdomen frequently removed, the smaller use of opium, and the earlier clearing of the bowels by enemata. The relief afforded by the poultices was very great and unmistakable. The clearing of the bowels on the third or fourth day by enema, may appear bad practice to those accustomed to keep the bowels confined by opium for a week or ten days, but after trying this plan Mr. Wells has become convinced that it is carried too far, leading to flatulent distension, keeping up sickness, and probably doing as much harm as the opposite extreme of those operators who give calomel and black draught if the bowels are not open on the second or third day. In this, as in all other cases, the Surgeon will do well to cast aside routine treatment, and, following the dictates of common sense, adapt his measures to the varying circumstances of the case before him.

ST. THOMAS'S HOSPITAL.

BOTH LUNGS WOUNDED—RECOVERY.

(Under the care of Dr. BARKER and Mr. CLARK.)

[Reported by Mr. H. GERVIS, House-Surgeon.]

THE following case is an instance of what is certainly very rare—recovery after punctured wounds of both lungs. It is of especial interest to the practical mind, on account of the therapeutic measures under which a recovery so unexpected was brought about. The treatment was that of the old school—free bleeding in the first instance, and mercury and opium to ptialism afterwards. We make no assertions as to the post hoc or propter hoc, but the facts remain:—that the man lost a large quantity of blood—so much that he was quite blanched—and took mercury, and that he made an excellent recovery. It is true, the loss of blood was not from the surgeon's lancet, but from the wounds; but this does not alter the effect which such loss must have had upon the circulation. The reader must, however, carefully bear in mind that the case teaches nothing as regards venesection for inflammation of the lungs, but only as regards wounds of those organs.

The following is a copy of Mr. Gervis's notes of the case:—

C. E., aged 37, policeman, was admitted into Isaac's Ward, 1.30 a.m., May 28, having, in an encounter with a negro, received some serious wounds on the chest—posteriorly there were five: two over the left scapula, just above the spine, and one close to its posterior border, probably entering the lung. On the right side there were two wounds, one about opposite to the scapular spine, and one below and to the inner side of the inferior angle, one or both of which must have entered the right lung; anteriorly on the left side there was a slight cut, and several about the scalp and hands, but unimportant ones. Venous blood was trickling from nearly all the wounds; his lips and cheeks were blanched, and he complained of great dyspnoea. There was no hæmoptysis; there was emphysema about the upper part of the chest and shoulders posteriorly. The wounds were brought together by strapping, but the venous oozing did not cease until the movements of the chest were restrained by a broad flannel roller. The following draught was administered, and repeated every two hours: sp. ether sulph. ʒj. solut. morph. mur. ʒss. ex aqua. The pain and dyspnoea and faintness were relieved, but he got no sleep; he was unable to lie on his back, but was propped up by pillows. In the afternoon, his bowels not having been opened, ol. ricini ʒiii. were given, which procured an evacuation. At night, tr. opii. mxxx.

May 29th.—Complains of considerable pain and difficulty of breathing. Orthopnoea continues. There is a good deal of emphysema, anteriorly, to be felt above the roller.

30th.—Roller was removed for the sake of examining the chest stethoscopically. Effusion of air and fluid was found in both pleuræ; both being above preternaturally resonant, and below preternaturally dull; more so on the right side than on the left. Corresponding absence of respiratory sounds: this dullness and absence of breath-sounds was as marked posteriorly as in front. A creaking sound is perceptible just below the left mamma. The heart is pushed out of its place toward the right side. There has been a little bloody expectoration, but not florid, or much—a few dark clots only. He has not much cough, nor fever. Pulse, 116, small and rather sharp; skin cool, tongue rather furred, but not dry. He takes light nourishment pretty well. Mercury was commenced. Pil hydrarg. gr. v.; opii gr. ʒ; 4tis horis. Rep. Haust. Morphine ether.

31st.—Has had a better night; has been easier since the removal of the roller. The amount of effusion is increased on both sides. The creaking sound heard on the left has disappeared. Breath-sounds inaudible on both sides below. Over the upper part of the right, breath-sounds are puerile. Respiration is not hurried; the skin cool; tongue furred, but moist. He seems, indeed, to have lost just the right quantity of blood to stay excessive inflammatory reaction.

June 1.—Respiration more audible on right side. On left side, mammary region almost tympanitic on percussion, and respiratory sounds very faint. The heart can be felt in its natural position. He has less pain and sense of weight in his chest; the cough is not very troublesome, and is unaccom-

panied with expectoration. He is feeling very weak. Pil hydrarg. et opii. 6tis horis.

2nd.—Better in every respect; rather low; gums just a little touched; pain in chest still less; a curious, splashing sound in the chest is heard on the left side, over the mammary region—connected with respiration, not with the heart; over the lower part of the left lung there is still dullness on percussion, but feeble respiratory sounds are just audible. Mist. pot. cit. ʒj. 6tis.

3rd.—Improving; no pain when quiet; sleeps well; mouth rather sore; tongue clean; bowels open; appetite good. There is no abnormal resonance on either side. Respiratory sounds still absent from lower part of right lung. Pil. hydrarg. alt. noct.

4th.—Has had a good night; is looking better; mouth decidedly affected by the mercury. Pulse better; the curious sound heard on left side of chest is not now to be heard, but feeble respiratory sounds are audible; heart sounds are more audible to the right of the median line of the sternum; dullness on percussion over lower part of right side not so great as it was: faint breath sounds audible on taking deep inspiration.

6th.—Was not so well yesterday; having pain in his chest and difficulty of breathing. This morning he is better again, though he had not a good night. The wounds in the back are slowly healing—one or two are suppurating.

7th.—Better.

10th.—He was put on a meat diet.

11th.—Has been up, and walked in the ward for a short time.

16th.—Allowed wine, ʒiv.

23rd.—Wounds all healed.

28th.—He is now able to get about with tolerable comfort. He has no pain in his chest, not even on taking a deep inspiration. The left is sufficiently resonant everywhere, and respiration normal. On the right side the chest is still dull over the lower lobe, and respiratory sounds feeble; anteriorly, also, some creaking sounds are perceptible, indicative of more or less pleuritic adhesion.

The man was now considered sufficiently well to be sent to the convalescent institution at Waltham, and consequently left the Hospital; but when attending at the Old Bailey a fortnight ago to give evidence against his assailant, I again saw him, and he then informed me that he was going on very well, though feeling weak and looking pale.

Medical Times & Gazette.

SATURDAY, JULY 16.

WHO IS A DOCTOR?

THE late Sir Robert Peel once put the kingdom into a state of monetary excitement, by asking in the House of Commons, What is a sovereign? Our Profession seems to be likewise on the road to a little Medical excitement; it having become a matter of importance for us to know, What is a Doctor of Medicine.

The Colleges of Physicians of the United Kingdom will be forced by the present condition of Medical matters to take up, and at a very early moment, the question: Whether their Licentiates can or cannot justifiably assume the title of Doctor? The question is really becoming very serious. It is one in

which the interests of a great number of our Profession, and more especially the interests of our Universities, are intimately concerned.

We do not conceal from ourselves the fact, that many difficulties surround the subject, and that the solution of it is not altogether so easy as, *prima facie*, men might think it to be. There are, however, certain principles of right and wrong to guide us here, as in most other matters, and we fancy that by keeping these steadily in view we shall not fail in the end to arrive at what is the right and the justice in the matter.

It is self-evident that from their very nature Colleges of Physicians have no power whatever of granting degrees. Their charters allow them solely the privilege of licensing men to practise as Physicians. We may assume it as certain, indeed, that at no period of history was it ever intended that the Licence of the College should supersede the University degree. This is manifest enough; for if the licence of a College contained within its powers the title of Doctor, of what avail becomes the University degree, and what is the use of a University?

But it may, and doubtless will be said, that Medical corporations are undergoing a process of fermentation, and that all the remnants of close-boroughism which may be still clinging to them are being quietly and rapidly worked off. We shall be told, as princely Teutonic wisdom a few years ago informed us of our country's institutions, that Medical corporations are on their trial; and that what was all very well in past days is no longer fitted for the requirements of these modern and enlightened times. If, it will be argued, you tell a man that he is fit, and give him the actual power and a seal and signature, to practise as a Physician—it is mere folly and contradiction to boggle at his assuming the title of Doctor of Medicine. The public, who is now all for freedom of trade in physic as well as in corn, can neither understand, nor will its common sense recognise, such a travestie as this; a Physician is a Doctor and a Doctor is a Physician, and argument to the contrary is the argument of antique, bigoted, and out-of-place conservative gold-stickism.

This is what will no doubt be cried out; and more than this. M.D.-less Licentiates will also argue, and with justice, that if prescriptive right, and the written law will not help them, still, that custom which is oftentimes as powerful as law itself, and sometimes even over-rides the law, gives them its sustenance in the assumption of the title of Doctor. They will say, and with truth: It was from one of your very Colleges that we first caught the inspiration. Your own wit first blew the breath of Doctor into the body of an M.D.-less Licentiate; and on your records still stands the memorandum which—all *in courtesy*, if you please—permitted him to take before the world this *courteous* title. And is it fair that you should now, to suit your own purposes, refuse to let us into the list of Doctors by Courtesy? But, indeed, if it comes to that, why have not we as much right ourselves to take the term, as you had to grant it, in courtesy?

Such, we believe, is fairly what the aforesaid Licentiate may argue by way of justification. And now let us see what may be answered to him, by those who think his assumption ill-founded. Let us see whether there be any principle of right and justice affected by his title-taking act. In the first place, we have the Universities, with their rights and privileges—seats of learning and of wisdom established for the teaching and edification and making of learned citizens; and are all their privileges to be set at naught? Is university education to be considered a thing of no account whatever? Are degrees all mere empty vanities? It is not for us, here, to answer these questions; but this in all justice we must confess, that the Professors of those high places have some right to be heard in their complaint—for where is to be found in past or present times, the accomplished

Physician whose name was not enrolled on a University list? Is it wise—even if it be just—to discourage the centres of knowledge? Will any one successfully pretend that university education is not the best of all educations? But if your Colleges ignore our degrees, will you not destroy us? Such will be the arguments of the Universities.

And then come the claims of all University men. Are their titles of M.D. useless paper? Do their Diplomas really give them no more grace than the Licence of a College can give? Is the heavy document a mere incumbrance—an expensive and antique ornament? And they will also say: What is it to us if in some past days, to please their purposes, a learned and imperious junta should have decreed that its College Licence would make a Courtesy-Doctor? The abuses and illegalities of past days can never justify a present wrong, or turn a standing evil into a permanent right. And, indeed, there have been always existing in the College referred to, men who have maintained the impropriety and the illegality of the proceeding. It has passed muster hitherto, has this proceeding, because the exercise of the privilege has been on the most limited scale; but now comes the grave question which the College can no longer pretermitt, which it is forced to answer: Must such a precedent be any longer maintained and sanctioned by College authority?

The College of Physicians of Edinburgh has by its proceedings forced, as we conceive, the London College to utter an opinion on this subject. It has assumed—not nominally but virtually—the privilege of a University, and is at this moment engaged in the issuing of Doctors on a large scale for the benefit of England; or to speak more correctly, it is granting its licence to a very considerable number of our Surgeons and Apothecaries during a year of grace!—to gentlemen who, as the College is perfectly aware, pay their 10*l*. because when they have received, per return of post, the quid for the quo—the Edinburgh licence—they intend to call themselves Doctors. And they do call themselves Doctors then, and the Edinburgh College knows it, and knows also that it is solely for *this* end that they pay their money. This method of granting a licence is what is called “marching with the spirit of the times;” and it is now to be seen whether the London College will or will not ignore such a species of enlightened progress. It would be, indeed, amusing, if it were not sad, to note what this free trade in physic can do for us. A list of gentlemen who were sent by the Edinburgh Council to the Fellows for election to their licence lies before us. We find in it the names of a very great number of gentlemen who have no other title than that of M.R.C.S. Everyone knows or may readily ascertain, if he be curious, the amount of *Medical* knowledge required of its members by the College of Surgeons—it amounts to absolutely nothing; and yet of such the Edinburgh College makes Doctors and Physicians! Is it not time for the London College to rescind a resolution, which is interpreted into a precedent by the Edinburgh College? The Edinburgh College has been called upon to express its opinion; but it is ever discreetly silent. It has not the moral courage to assert either that its licence does not, in its opinion, give the bearer title to add Doctor to his name; or that the title may be honourably adopted by its ungraduated Licentiates.

It seems to us, that if Colleges of Physicians are of service at all in furthering the ends of Medicine, they can only be so by taking a position highly scientific and honourable, and by demanding from those who seek admission to their honours proofs of extensive Medical knowledge and a certain standing in the Profession. If they throw their Licences about right and left for a small fee to the first comer, it must follow inevitably, that in the end the possession of their licences will no longer be a credit to the possessor, and therefore, that the Profession in the end will not care to seek them. It follows that a College of Physicians ought to demand an honourable

degree from all its Licentiates; and ought, as far as its powers permit, to prevent and discourage those of its Licentiates who possess no degree from assuming the title of Doctor.

We shall doubtless have occasion to return again to this subject; and we will then enter upon and fairly meet what may, with a show of reason, be considered the individual hardships which this mode of proceeding would occasion. This only we will now say: that it is utterly impossible, in the entangled state of the politics of the Profession in this country, to lay down rules which shall satisfactorily meet every case; but, nevertheless, it is the clear duty of a great corporation to legislate for the bulk of its members and not for the individual. It is equally the interest as well as the duty of institutions like the College of Physicians to maintain a high professional standard of acquirements from its members. These colleges depend solely on their high and honourable reputation for their actual existence. Their legal privileges custom once, and now law, have abrogated; so that they have manifestly no foundations whatever to rest upon, other than that of good character. The instinct, therefore, of self-preservation warns them to maintain, at all hazards, that excellent virtue. Every single act which tends to bring the College down to a low general level is a suicidal act.

THE WEEK.

WE understand that a subject of very great interest to the Profession at large is undergoing discussion at the College of Physicians of London at the present moment. Perhaps no question of greater importance has come before the Fellows for discussion since the passing of the Medical Act. It is one which affects very intimately the future position of the large body of our Professional brethren—the General Practitioners of this country. Can the College of Physicians frame a bye-law, such as will enable the General Practitioner to receive from the College the honourable title of Licentiate of the College? This is, in a word, what the Fellows of the College have now to decide. We understand that the proposition which is to be brought before the Fellows under the authority of the Charter Committee is to this effect. The College proposes to establish by bye-laws a third class of Medical men, viz., *Licentiates in Medicine*, its present Licentiates taking the title of *Members*, and retaining all their rights and privileges. Thus, then, the College would consist of Fellows, of Members, and of Licentiates. This new class of Licentiates would be permitted to practise pharmacy, to make up Medicines, but only for their own patients. They bind themselves not to take the title of Doctor, or in any way to assume that of a Member or a Fellow of the College. Such are, in outline, the main features of this important document. Without further discussing its merits or demerits, we would now only observe that there is, as we hear, a party in the College who desire to see the object carried out in a different way. This party think that an attempt should now be made to establish a perfect General Practitioner, a Licentiate in Medicine and Surgery; in fact that the two great Colleges of the country—the College of Physicians and the College of Surgeons—should combine, and form a Board for the purpose. Such a scheme, we must say, has our hearty concurrence. We believe that a diploma granted by a joint Board of these two Colleges would grant the very honourable title which is required to make the Practitioner of this country what he ought to be. This is a scheme which we believe would give universal satisfaction. It recommends itself strongly to the common sense of every one; and we cannot doubt that if carried out, the Medical Council would take the matter in hand, and obtain an Act of Parliament which would legalise the licence before the world. Difficulties, of course, in the constitution of such a joint Board must necessarily arise, but we cannot think them insuperable.

There can, surely, be only a little straightforward determination required on the part of the two Colleges to bring to a happy conclusion such a desirable object; and if we are not mistaken the path thereto has been already opened by an interchange of sentiments on the subject.

The Medical world of Berlin has lately been excited by the departure of M. Schoenlein. A Deputation, consisting of Virchow, Langenbeck, De Græfe, Wilms, etc., waited upon the Nestor on the occasion, and presented him with an address. In this we read: "It was you, Sir, you renewed the link which unites Medicine to the natural sciences; who enriched German Clinical Medicine with all the auxiliaries requisite for modern investigation; it was you who excited an energy among students unknown in the history of our science, and which has been propagated from Germany through all the Medical Schools of the civilised world." His retirement seems to be connected with his duties of Physician to the King. M. Frerichs is to be his successor in the chair of Clinical Medicine.

A case was tried at Guildhall on Monday, which shows the great risk Surgeons continually run from the tricks of ungrateful patients. Mr. Davenport, of Abridge, in Essex, was called to the wife of a blacksmith in 1855, who had injured one of her arms by falling from a cart. He thought there was a fracture, and put up the arm in splints. Other Medical men saw her, but accepted Mr. Davenport's report, and did not examine the arm. Some two months after the accident, Mr. Bowers, of Romford, was called in, and said that there never had been a fracture, but that the wrist had been dislocated, and it was then too late to reduce it. The poor woman suffered very much, and it was asserted that the nervous system had been so shattered in consequence of the injury, that she became maniacal, and was now in a lunatic asylum. The defence was, that the plaintiff had never complained until Mr. Davenport had sent in his charge for attendance, and then brought an action four years after the accident occurred. That the lunacy had followed an attack of fever, and had nothing to do with the injury, and that the result of the treatment had been satisfactory, as the woman has a very good arm, and is now able to use a needle in the asylum. Mr. Davenport asserted that there had been no dislocation, and only one of the bones of the forearm fractured, and that his treatment had been right and proper. We are happy to add that the Doctor, for once, obtained justice; but it is very doubtful if he will ever get his fee.

It is always interesting to read what intelligent foreigners say of our institutions, although it is somewhat provoking to observe the errors they fall into. M. Liegard, recently on a visit here, in a communication to the *Gazette des Hôpitaux*, is speaking of Guy's Hospital when he says:—

"The sisters fulfil the same duties as our hospital religious, and it is they alone who attend to the dressings, at least at the time of the visit, unfastening the apparatus for the examination of the injuries, and replacing it again. No student ever assists in these dressings; far different to the pupils in the French hospitals, to whose care the wounded are confided, and who themselves wash the parts, change the dressings, and assist the Surgeon in putting up the fractures. At the time of the visit they lay aside all their dandyism, and cover their worst clothes with a white apron. But for the English students, the hour of visiting is the hour for the toilette; and a little time before the arrival of the Surgeon they repair to their rooms to dress, glove themselves, and they even carry canes; and it is in this parade costume they visit the patients!"

After expressing his great admiration of the laboratory, dis-

secting-rooms, and especially the museum at Guy's, M. Liegard states that the students there, as well as those of the other London schools, pay on their entrance £100, which franks them for the period of their Medical studies; "the student is boarded and lodged during all this period by the Hospital administration, and between six and ten he is allowed to go out for exercise in the town, but at all other times he is obliged to remain within the establishment." He maintains that this splitting up Medical instruction into as many schools as there are hospitals (of which he says there are forty or fifty in London) is eminently mischievous to the student, as it is quite impossible that the Medical officers can find time to give that vast course of Medical instruction furnished by the fifty-two Professors of the Medical Faculty of Paris.

"This it is which renders perfecting courses of study necessary to the English students, so many of whom resort to Paris for these, without which their education would remain incomplete and limited."

All this from a well-intentioned visitor, who says he comes to London having English friends here! They might have taught him better.

A curious case has just been tried before Mr. Justice Byles; the first, we believe, in which an action has been brought against a Medical witness for non-appearance in a Court of Law. The plaintiff, Mr. Yeatman, a barrister, took proceedings in the Ecclesiastical Court to annul his marriage, on the ground of his wife's insanity. Dr. Dempsey, the defendant, made an agreement with the plaintiff, under which the defendant was "to take charge of his wife, and to watch her, and assist to get up the case for a divorce," and the plaintiff was to pay all expenses out of his pocket, and also to remunerate him for his time and labour after the trial should have been decided. During the six months that the plaintiff's wife resided with the defendant he had frequent opportunities of seeing her state of mind, and he had expressed his belief that she was not sane, and that the plaintiff ought to succeed in obtaining his divorce. Proceedings were then commenced in the Divorce Court, and the defendant was communicated with, and came to London the day before the trial of the cause, and had an interview with the plaintiff, and all was arranged, as the plaintiff believed, for their meeting in court the next morning; but when the trial came on the defendant was not present, and left a note saying he would have nothing more to do with the case, and he had gone away from town. The want of the defendant's evidence, which was by far the most material, had rendered it necessary for the plaintiff to withdraw the suit, and the expenses he had incurred amounted to above £500. Dr. Winslow had also been consulted as to the state of mind of Mrs. Yeatman, and he had given a certificate of her derangement of intellect. He was present on the day of the cause coming on, but as he said his evidence would depend chiefly upon what Dr. Dempsey said, he was not called as a witness. The defence now set up was, that there was no contract on the part of the plaintiff to appear as a witness in the case, and that the plaintiff had neglected to pay the defendant what he was entitled to receive. The defendant averred that he had several times asked the plaintiff for money, but had been refused until after the trial was over, and that he had told the plaintiff he should not proceed further in the case unless he received a sum of money. The plaintiff's answer to this was, that the defendant had received more than his costs, and that the agreement was that he should receive nothing more until the trial was over. Serjeant Pigot and Mr. Beresford appeared for the defendant, and submitted that this was the first time that such an action had ever been brought. They admitted there was some understanding between the parties that the

defendant should appear as a witness, but it never amounted to a contract on the part of the defendant. A contract to assist in getting up the case was not a contract to appear as a witness, and it was the plaintiff's duty to have subpoenaed the defendant, which he neglected to do. The jury returned a verdict for the plaintiff. Damages, 50*l*.

The "Founder's Day" of the Medical Benevolent College has passed off in a manner which must be highly gratifying to its indefatigable and benevolent founder, and to all the friends of the Institution. Speeches were made, prizes distributed, and dinner eaten in orthodox fashion; a good deal of money collected, and a very pleasant day passed in the delightful spot where a College has been raised, in which 170 boys are already assembled, and which bids fair to rival the very best of our public schools. The Bishop of Bath and Wells remarked with great truth, that if the boys wanted an example of patient, steady, careful perseverance, let them look to the founder—Mr. Propert. "He came up to London," said the Bishop, "without friends, without much money, and without any advantages, excepting those which always attend the sound purposes of an honest, good, and faithful man. God prospered the work of his hands, and then he conceived the idea of doing something for those of his honourable profession who had been less fortunate. This magnificent building which adorned this glorious landscape was owing to the perseverance and determination of one single man." It is well that all this should be remembered.

The Recorder at the Central Criminal Court last week, awarded to the notorious "Ear Doctors," Watters and Edwards, eighteen months imprisonment. It was stated that Walters, otherwise Watters, had above twenty years ago been charged with arson, and had suffered six months' imprisonment for making a false declaration to a Surgeon's certificate.

The Adulteration of Food Bill was, on the 7th inst., we are glad to say, passed by the House of Commons to a second reading. Of course there will always be people to cry out against such a measure, as being inquisitorial, un-English, and so forth; and to defend, as they call it, the rights of the traders; but it is curious that gentlemen who have such bowels of compassion for the retailers of daft and chicory, and saw-dust, should take so little care and have so little compassion for the tortured and robbed stomachs of the millions on whom especially and with severity falls the brunt of all this adulterating commercial iniquity.

THE trial of Dr. Smethurst is adjourned until August 15th, in consequence of one of the jury having been taken seriously ill. The Austro-Gallic armistice ends on the same day.

It was stated by a leading dentist of Chicago, in a recent address to his brethren, that the value of the gold plate and leaf used in the United States for the replacing and repair of defective teeth, was 2,250,000 dols. This is a fact that tests the existence of a high civilisation, and a good deal of toothache in that blessed land.

A NEW MALADY.—A letter from Venice of the 24th ult. in the *Austrian Gazette* of Vienna, states that a malady, hitherto unknown, has broken out there. It begins with a pricking sensation in the region of the stomach and the bowels, which is afterwards followed by fever, cramps, and convulsions, and in a few hours the patient becomes a corpse. Upon dissection, the whole stomach and the bowels have been found coated with a thin viscous pellicle, which prevented the free circulation of the blood. As yet there have been only five or six victims, but none of those attacked have escaped death.

REVIEWS.

The Psychology of Shakespeare. By J. C. BUCKNILL, M.D., Medical Superintendent of the Devon County Lunatic Asylum, etc., etc. 8vo. pp. 264. London: 1859.

FEW persons thought that anything new could be said about Shakespeare. But Shakespeare is like Nature herself, who can be discoursed of for ever, yet without monotony or exhaustion. Certainly Dr. Bucknill's treatise is like that of no other commentator; he has looked at Shakespeare from a point of view which no predecessor has commanded, and he has given us a work of most decided originality. Coleridge, indeed, may be said to have analysed Shakespeare as a Psychologist; but Coleridge's knowledge of mind was chiefly introspective and speculative, and wanted that practical education in aberrant as well as in healthy mental operations, without which some of Shakespeare's most wonderful creations can hardly be understood. We will venture to say that Dr. Bucknill has invested Lear, and even Hamlet, with quite a new interest; and that if we would understand these plays properly we must take his starting point. The tracing out of Lear's madness is excellently done, and it is the best compliment to Dr. Bucknill to say that we almost forget the lucid exposition of the Commentator in our admiration of the exquisite skill which the commentary shows to have been possessed by the Poet. Indeed so great is this skill that we are almost led to question whether Dr. Bucknill has not overrated it, and whether, in fact, it is not merely by some admirable chance that Shakespeare has created a character in which is pictured with such wonderful accuracy the first faint causes, and the subsequent almost necessary growth of insanity. And as some have supposed that a Poet is not really a deep thinker, in fact is seldom so, but is merely a man whose power of expression suggests things foreign to his original thought, and, indeed, often above it; so we might suppose that Shakespeare's delineation of Lear did not proceed from any intelligent study of insanity, but was merely an instance in which mere dramatic power, and the art of adapting circumstances to produce stage effects, produced the impression of a deeper knowledge than was really possessed by him. Whoever may hold such an opinion will, however, find it much shaken by Dr. Bucknill's analysis. So coherent a picture of insanity as is given in Lear, a picture which is wanting in no detail, and is yet not disfigured by the intrusion of unreal colours, could hardly result merely from a happy accident. And, as if to guard us against such a notion, Shakespeare has introduced into his play a specimen (in Edgar) of feigned insanity, which serves as an excellent foil for the true disease. In his elaborate and curious notes to Thomson's "Seasons," the late Dr. Anthony Todd Thomson indicated this point.

"The madness of Lear," he says, "is unequalled for correctness of detail by any prose descriptions of the disease in Medical writers; and the distinction between the most skilfully feigned and the real disease was never drawn with a more masterly pencil" (a).

But if we admit that Shakespeare drew Lear not by a kind of hap-hazard, but with a real insight into insanity, how wonderful was such insight. How did he get it? Where were his models? Who were his teachers? Dr. Bucknill thus endeavours to account for it.

"Although for many years the dramas of Shakespeare have been familiar to the author, the extent and exactness of the psychological knowledge displayed in them, which a more diligent examination has made known, have surprised and astonished him. He can only account for it on one supposition, namely, that abnormal conditions of mind had attracted Shakespeare's diligent observation, and had been his favourite study. There is no reason to suppose that when Shakespeare wrote, any other asylum for the insane existed in this country than the then poor and small establishment of Bethlem Hospital, the property of which had been taken from the monks by Henry the Eighth, and presented to the city of London for conversion into an asylum, only seventeen years before the poet's birth.

(a) Thomson's "Seasons," edited by A. T. Thomson, M.D. F.L.S.: 1847. P. 237.

In his time the insane members of society were not secluded from the world as they are now. If their symptoms were prominent and dangerous, they were indeed thrust out of sight very harshly and effectually; but if their liberty was in any degree tolerable it was tolerated, and they were permitted to live in the family circle or to wander the country. Thus everyone must have been brought into immediate contact with examples of every variety of mental derangement, and anyone who sought the knowledge of their peculiarities would find it at every turn. Opportunities of crude observation would therefore be ample; it only required the alembic of a great mind to convert them into psychological science." (Preface, p. vi.)

This explanation seems a reasonable one, and we must therefore assume that Shakespeare studied insanity with a success which astonishes even the enlightened psychologists of our days. This is infinitely more wonderful than that he should have picked up a few technical law terms, and have learnt to apply them rightly. But for the full extent of this wonder we must refer the reader to Dr. Bucknill's own pages, where he will find not only Lear and Hamlet, but Macbeth, Constance, Ophelia, Timon, Jacques, and Malvolio, discussed with the science of a profound psychologist, and with the vigour and powers of expression of a practised writer. We shall be surprised if the reader does not find that even the well-known passages of his favourite parts acquire a new significance, and give him a novel pleasure.

MEDICO-CHIRURGICAL USES OF VULCANISED INDIA-RUBBER.

THE Medico-Chirurgical applications of caoutchouc air-bags are being again brought under the notice of the profession in this country; but the merit of originality belongs to M. Gariel, whose proposals appear to be ingenious and practically useful. We believe that our readers will find the following extracts from M. Gariel's *Mémoire* (a), translated and sent to us by Mr. Jardine Murray, of Brighton, to be interesting and instructive. The woodcuts are selected from among M. M. Gariel's illustrations.

FIG. 1.

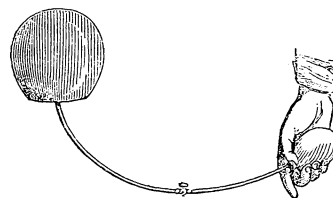

FIG. 1.—Caoutchouc air-bag, which may be used either as a pessary in displacement of the uterus, as a plug in uterine hæmorrhage, or as a dilator of the vagina.

FIG. 2.

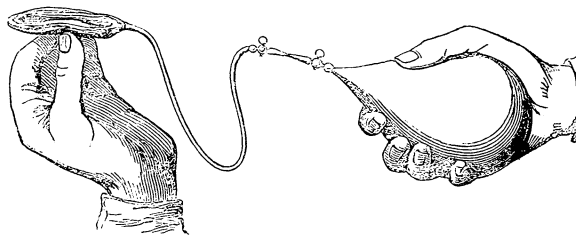

FIG. 2.—A similar air-bag of large size is here represented in the collapsed condition in which it ought to be introduced. The caoutchouc bag is distended to the requisite extent by compressing the insufflator, which is represented as held in the right hand. A ball-valve syringe may possibly be found preferable to the bag insufflator here represented.

(a) "Mémoire sur les applications Médico-Chirurgicales du Caoutchouc Vulcanisé." Par M. M. Gariel, docteur en Médecine, ancien Interne Lauréat des Hôpitaux et Hospices civils de Paris, Membre Titulaire de la Société Anatomique, et de la Société Médicale d'Observation. "Ce Mémoire a été couronné par l'Académie des Sciences en 1851."

FIG. 3.

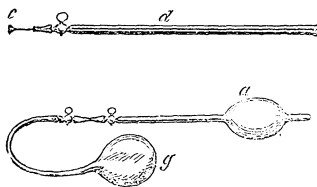

FIG. 3.—This figure represents M. Gariel's application for dilating strictures of the urethra, œsophagus, cervix uteri, &c. In its collapsed state the bulb is hardly to be detected. To facilitate introduction, the tube is fitted with a wire stylet *c d*, which is withdrawn when the end of the apparatus has been carried past the stricture. An insufflator, *g*, is then attached in the usual way, and the bulb, *g*, may be distended to the necessary degree. M. Gariel's ingenious chapter on this subject will amply repay perusal.

"APPLICATIONS FOR DILATATION.

P. 35. B. AIR SOUNDS FOR THE DILATATION OF THE VAGINA AND CERVIX UTERI.

"186. The sounds with bulbs applicable to the dilatation of the vagina and cervix uteri, must (like the bulbous sounds already described,—œsophageal, urethral, etc., p. 33) be introduced empty of air.

"187. The continuous and progressive dilatation which may be obtained by insufflation, is so powerful, that all congenital or acquired strictures of the vagina must give way before it, unless these latter be complicated with extremely hard cicatricial products (bridles).

"188. Their application is easy, however great the degree of stricture, since a sound 3 millimètres in diameter, may readily be made to produce a dilatation of 2 or 3 centimètres. It may be necessary, however, to use sounds of various sizes; but it is only after having employed the smallest sounds that the larger sizes can be used.

"189. Might not this property of the bulbous air-sound be turned to advantageous use in inducing premature labour in cases of deformity of the pelvis? ('Ne pourrait-on également tirer parti de cette disposition des sondes à renflement pour provoquer prématurément l'accouchement dans les cas de vices de conformation du bassin?') (b)

"HÆMOSTATIC APPLICATIONS.

P. 41. A. AIR-PLUGS.

"219. These plugs consist of a caoutchouc tube, terminated by a bulb which is scarcely noticeable when empty, but is susceptible of considerable enlargement when distended by insufflation. (See fig.)

FIG. 4.

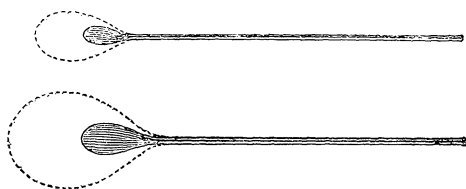

FIG. 4.—Air-bags, of various sizes, for plugging or dilating the vagina, cervix uteri, nasal fossæ, etc. The dotted lines indicate the periphery of the bags when moderately distended by air.

"220. They are applicable to all cases and to all cavities in which it is usual to resort to plugging.

"221. They are unalterable, and may remain in position during several days without undergoing the slightest decomposition.

"222. They apply themselves exactly over the parts which are the seat of hæmorrhage.

"223. Their volume may be diminished at once, or by degrees, without producing any alteration in the shape of the apparatus, or any folds in its walls; the blood cannot, therefore, escape through one of those longitudinal folds which always exist when any amount of air is withdrawn from a non-elastic bladder.

"224. Should the hæmorrhage reappear from their volume being too soon or too rapidly diminished, they may be re-inflated with the greatest ease.

(b) On a future occasion we may take leave to show how fully this expectation has been realised in Continental obstetric practice.

"225. These plugs may be made of vulcanised caoutchouc, or of caoutchouc imperfectly vulcanised, which latter I prefer in this special instance. When made of vulcanised caoutchouc, their walls are too resisting to allow of their being dilated otherwise than by an insufflator, and I would rather avoid the necessity of using an instrument which may have been forgotten and which at all events renders the apparatus less portable. Besides, in cases of hæmorrhage there is often no time to lose, and I think pulmonary insufflation may be more quickly accomplished than artificial insufflation can be.

"226. These plugs are so small that they may easily be carried in a Surgical pocket-case.

"227. The air-plugs suitable for the vagina, are of larger size than those for the rectum or nasal fossæ.

"228. The uterine plugs are always used successfully, except in flooding after delivery. Bleeding may always be immediately checked when it is dependent on polypus, cancer, etc.; or when it occurs during the early months of pregnancy. There is only one exception to this rule—when the os uteri is exceedingly dilatable, as after parturition at the full time.

"229. In such a case, if, after the application of a plug to the vagina or even to the uterine cavity, the flow of blood have been arrested, it were unsafe to infer that the hæmorrhage is necessarily checked; for internal hæmorrhage might be going on, and if unattended to, might cause the most serious accidents.

"230. But it is not certain that this would occur. It is questionable whether, the passages being hermetically occluded, the blood would flow in sufficient quantities to fill up the dilatable cavity of the uterus. Air is not indefinitely compressible, and there is every reason to believe that the accurate occlusion of the vagina (which may be so easily obtained) would suspend the hæmorrhage after the loss of a few ounces of blood, and without it being necessary to apply direct compression at the point from which the hæmorrhage originates.

"231. A very simple experiment proves how easy it is to produce hermetical occlusion of the vagina:—I take a tumbler a quarter or half filled with water; in the upper and empty portion of this I place an air-plug, which I insufflate until it presses against the walls of the tumbler. If I then invert the tumbler, the water contained in it will not flow out, but remains completely shut up, although no means is employed to retain the air-plug in position. This precisely illustrates what takes place in plugging, and shows the action of the distended plug in opposing the escape of blood. It is further worthy of notice, that so closely does the caoutchouc adhere to the walls of the tumbler, that by pulling the tube attached to the air-bag, the tumbler is easily raised; and the result is the same, whether the tumbler be more or less filled, and whether it be cylindrical in shape, or conical like a wine-glass.

"232. By the use of these air-plugs we may entirely control all hæmorrhages from the nasal fossæ, a circumstance explained by the solidity of their walls: but it is necessary to be careful that one extremity of the plug reach as far back as the pharynx; for, without this precaution, blood might continue to flow into the œsophagus.

"233. We must be prepared for a symptom which may occur when the plug is too much distended by insufflation. The patient complains of a painful sensation at the epigastrium, he grows pale, and the forehead is covered with perspiration. These phenomena continue as long as the plug preserves its exaggerated distention, but disappear as soon as a little air is allowed to escape, and the volume of the plug is reduced to more convenient proportions. To what cause may these symptoms be attributed? Partly, no doubt, to the fact that the air-bladder, by its excessive distention, occludes simultaneously both the posterior openings of the nasal fossæ; but the symptoms of dyspnoea and of threatening suffocation are probably not entirely dependent on mechanical obstruction to respiration; there is reason to believe that they are in great measure due to compression of the par vagum.

"234. Whence the important precept never to carry the distention of the air-bladder to excess, and never to leave the patient immediately after the application of the plug."

Those who are interested in the matter will find the various applications (compression, dilatation, confinement, plugging, etc.) of the vulcanised caoutchouc bags further

referred to in the passages indicated by the following references:—

PROGRESS OF MEDICAL SCIENCE.

Selections from Foreign Journals.

ON THE EMPLOYMENT OF COMPRESSED SPONGE.

By Dr. BATCHELDER.

WE have already noticed (vol. xxxvi. p. 459, xxxvii. p. 18) the successful employment of this substance made by Dr. Batchelder and other trans-Atlantic surgeons, and we now quote some additional observations.

The compression of the sponge is best executed by means of a copying machine, or in default of this, by laying it between pieces of board upon which heavy weights are laid. If desired to be at hand at all times it must have been kept for weeks or months under the compressing power. When wanted to be used as a tent, the compression should be effected by winding some thread or thin cord around a piece of clean, well-moistened sponge, removing the thread after the sponge has become thoroughly dried. Or, the sponge may be soaked in a solution of gum arabic before winding, and the tent afterwards smoothened into a proper shape by means of a knife. The winding is facilitated by transfixing the sponge by an awl which is afterwards removed. The tent should always be prepared with mucilage, and not with water, when intended to be used for dilating the canal of the cervix uteri, or any other part where moisture might induce premature expansion, i.e. before it can be properly inserted; also when it is desirable to avoid rapid dilatation, which sometimes causes considerable pain and uneasiness. When the tent can be introduced with facility, the mucilage may be dispensed with; and when it is to be introduced into any internal part it should be transfixed by a needle and thread for its withdrawal.

The production of firm, equally-diffused, and softened pressure by the application of plates of compressed sponge, and then saturating these with water, was first tried in *inflammation of the breast*, and an account of its success will be found in our pages already referred to. In the tent form it has been used to dilate the cervix uteri in *sterility*, *difficult menstruation*, and other affections of this part. The tent should be introduced by means of a pair of long-bladed forceps, or by fixing it at the end of a small, round, slightly-curved stilet, about twelve inches long, reduced to a point, with a shoulder about five-eighths of an inch from its extremity. The portion between the point and the shoulder should be small enough to be received into the base of the tent, and long enough to keep it steady when being introduced, while the shoulder enables the operator to push it safely home. When, on account of the smallness of the canal, the tent can only be introduced with difficulty, the cervix should be dilated by means of fine metallic dilators, successively increased in size. They should be about an inch and a-quarter long, and have a thread attached to them, which being attached to the patient's clothes prevents their being dropped or lost. In some cases a few days, and in others weeks, may be required for such dilatation. The tent should not be allowed to remain longer than twenty or twenty-four hours, and when it is removed the vagina should be well syringed out. When it is desired to induce premature labour, the tent must be continuously applied, or be replaced by a larger, after it has become expanded. In cases of pregnancy attended with hæmorrhage, we sometimes find the os partly open, but inflamed, or indurated and unyielding—not dilating so as to allow the embryo and placenta to pass in cases of abortion. There may be, indeed, slight parturient pains, but not sufficiently strong. A sponge tent which is sufficiently large to fill the canal should be inserted. This will not only constitute the best tampon, but cause efficient uterine pain, and, at all events, dilate the canal sufficiently to admit of the introduction of instruments to complete the delivery.

Dilatation of Sinuses.—These may be dilated to any desirable extent by the tent, and most of them will heal when a free discharge is thus promoted. From day to day the tent should be lengthened as well as enlarged.

Fistula in Ano.—Many of these cases can be cured by the tent without operation. When an abscess forms near the rectum, it may be separated from this by a mere septum, which remains unruptured as long as a free external discharge is secured. If soon after the bursting of an abscess the tent be fairly and fully inserted, it will not only absorb the matter and prevent its burrowing or pressing upon the septum, but secure it a ready exit by keeping the external orifice open. An opening in the gut is prevented, and the sore heals from the bottom. Every Surgeon knows that a communication between the abscess and the intestine does exist sometimes prior to the external opening; but in the majority of instances the external opening first takes place.

Diseased Bone.—The use of the tent is especially appropriate when a fistulous passage leads to diseased bone. "In the course of a fortnight, I have in such cases dilated the sinus so as to be able to place my thumb and three or four fingers directly upon the diseased bone and remove the sequestrum, if one existed, or if there were caries to remove the diseased portion of bone by repeated application of the sponge. Now caries is an ulceration of bone, which in some respect resembles cancer of the soft parts. In this disease, the relative proportions between earthy and animal matter entering into the composition of the bone seem to be disturbed. In some cases the animal matter, or vascular portion, exceeds the earthy, and then we may have decaying bone with fungous, bleeding masses. In others, the earthy matter may predominate and produce irritation or cause exfoliation. Nature's method of cure, particularly in the last case, is to get rid of the earthy matter, either by solution or absorption, or by wholly depriving it of its vitality, when we have exfoliation or necrosis. The reason why caries is so tedious and difficult of cure, is that the earthy matter, partially or wholly deprived of its vitality, keeps up a constant irritation, which prevents a portion in the immediate vicinity from being duly nourished. Nature, as suggested, causes the death of the diseased portions, and then throws them off. The Surgeon, for the same purpose, applies the external cautery or the gouge and chisel; but the action of the sponge is less dangerous, painful or repulsive, and more certain." Its action upon diseased bone was discovered by the author accidentally, and he has since found most cases of caries yield to its application. Applications of plates of compressed sponge have also been very successfully resorted to in cases of enlargement of the bones, especially in syphilitic nodes.

Stricture of the Rectum.—For dilatation of *stricture* of the rectum the sponge tent may be used with great effect. It may usually be prepared without mucilage, except when there is much irritability, when it dilates too rapidly. In some of these cases its toleration has to be secured by introducing, an hour or two previously, a suppository formed of watery ext. of opium. gr. ii., ext. hyoscy. gr. i., ext. belladon. gr. ½.

Hæmorrhoids.—The sponge tent introduced just within the sphincter may be successfully resorted to for the compression of hæmorrhoidal tumours, and also for the suppression of hæmorrhage from the rectum. It should be transfixed with a thread.

Stricture of the Urethra.—A full-sized metallic instrument should be first carried down to the stricture, and pressed firmly against it for a longer or shorter time, according to the degree of uneasiness it produces, when it should be withdrawn, and a tube, open at both ends, containing the tent and a piston, introduced, and pressed against the stricture. When the tent has been forced out of the tube, the piston may be withdrawn, and a few drops of water passed down the tube to the tent, which is kept steadily in or against the stricture. In a short time the tube also may be withdrawn, and the tent having expanded so as to retain its place, may be allowed to remain as long as may be deemed necessary. To prevent all accidents, the sponge is transfixed by a thread, to the other end of which is affixed a button. There need be no hurry in withdrawing the tent, the attempts at its expulsion during micturition helping to dilate the stricture. If the stricture is very irritable, a few drops of saturated solution of ext. belladon. and watery ext. opii. may be passed down to the stricture half an hour before the introduction of the tent, the patient

passing water shortly before the introduction of the tent or the solution.

Dilatation of the Female Urethra.—The tent is admirably adapted for this purpose, and when incontinence follows its use, this seldom lasts beyond a week or ten days.

Malignant Growths.—Dr. Batchelder has found the sponge successful in some cases of cancer, and thus explains its operation:—"The pressure occasioned by the expansion of the compressed sponge disturbs the cancer cells, and forces them out of their place, affects their consistency, and causes them to be dissolved; and the tumour, thus freed from its malignant ingredients, may be more readily removed by absorption, or if not absolutely removed, it may be so divested of its malignity as to remain harmless for years. . . . This remedy may, and undoubtedly will, fail when either the constitution or the surrounding parts are to any considerable degree affected. The cancerous diathesis, even when somewhat apparent, does not, however, seem to preclude its use, as will be seen by the following case. . . . When it can be borne, whether compressed or not, I am satisfied that the sponge is an excellent application to cancerous and certain other ulcers of a vitiated character. The secretions of such ulcers seriously affect the health, and often break down the constitution, and ultimately destroy life, all of which deleterious consequences the sponge, by absorbing the secreted fluid, tends to prevent. In the removal of the elevated, indurated edges of the callous ulcer it is exceedingly useful. The sponge should be large enough to overlap the edges of the ulcer by at least half an inch."

Swelled Testis.—The testis should be turned up on the abdomen and the sponge and spica bandage, properly modified, applied. For a day or two uncompressed sponge may be used; and when the patient has become used to this compressed sponge may be bound on, the patient being kept in bed, and the bandage readjusted whenever it slips off. The removal of the swelling, as also of the tumefaction of the glands of the groin, is much promoted by the occasional administration of an emetic.

Vegetations of the Glans Penis or Prepuce may be speedily removed by turning the organ up over the pubes, and applying the sponge and a bandage, a flexible catheter being kept in the urethra. The growths are often destroyed with great rapidity, the greatest inconvenience being the confinement to bed.

Non-malignant Tumours.—Enlarged lymphatic glands may by this means be speedily removed; and it is almost a certain means of preventing the suppuration of bubo. In some cases of enlarged inguinal glands, a hernial truss, with a stiff spring and a glass pad, has also been used, the pressure being graduated by interposing pads of cloth between the spring and the body on one side or other of the tumour.

Enlarged Joints.—Whether the enlargement has arisen from effusion into the joint from synovitis, or from infiltration of the cellular tissue surrounding it, no remedy has succeeded like the sponge, especially under the latter circumstances.

As a Styptic.—This the author illustrates by its efficacy in wounds of the palmar and plantar arteries. "The phenomena attending these wounds are often somewhat peculiar. The blood, forced extensively into the surrounding cellular substance—perhaps under the aponeurosis—seems to come welling out from a considerable surface, which renders it very difficult to find the wounded vessel. If the surface be scraped again and again with the handle of a scalpel, the extent from which the blood issues will be lessened down to a small space. Upon this let a piece of compressed sponge, shaved to a point, be applied, and perhaps another broader piece, followed by a compress and bandage, the wounded part being then brought to an acute angle with the limb above, to which it may be bandaged or confined as closely as consistent with comfort. The uneasiness occasioned by this procedure may be relieved by extending the limb a very little from time to time, just to give temporary relief. Although it is undoubtedly a fact that the position of the limb alone will in most cases control the hæmorrhage, in order to be sure I employ the sponge also. With the influence of this arrangement of parts upon the arterial circulation of the hand and wrist I became accidentally acquainted many years ago, by failing to feel the pulse when the arm was much flexed at the elbow. On further examination, the same result, though less decisive, was found to follow the flexure of the leg on the thigh, and still more that of the latter upon the trunk. In some, these positions

will render the pulse at the wrist, and also the beat of the anterior and posterior tibials, very weak, or quite imperceptible at the points where their pulsations are most readily felt—a fact of too much importance not to be made available in practice, especially in the treatment of wounded arteries of the hand or foot. It remains to suggest the trial of position in the treatment of popliteal aneurism. The object in such cases being the coagulation of the blood in the tumour, might not this be effected by bending the thigh upon the pelvis and confining it in that position for several days, lessening its irksomeness by the administration of opium, or occasionally ether or chloroform, or by slightly altering the position of the limb?"

Varicose Veins.—In a case recently treated by the author compressed sponge was applied over the internal saphena as it passes behind the condyle, and kept on by a vulcanised India-rubber bandage. When the sponge was wetted it effectually compressed the vein, and the relief was complete. —*New York Journal*, May, pp. 301—330.

GENERAL CORRESPONDENCE.

THE EDINBURGH COLLEGE OF PHYSICIANS.

LETTER FROM DR. WOOD.

[To the Editor of the Medical Times and Gazette.]

SIR,—I regret to be obliged so soon again to intrude on your attention.

At page 44 of your last week's number, appears a letter from Dr. Christison, the head of that party in the College of Physicians of Edinburgh which has for years striven for the not "very dubious" cause of University monopoly.

In this letter Dr. Christison professes to give, on the authority of another Fellow, an account of what took place at a meeting of the College of Physicians, which account conveys anything but a correct impression of a statement then made by me.

Dr. Christison's statement is as follows:—

"I have delayed answering your letter in the hope that the question might be cleared up by our College of Physicians, at a meeting held yesterday. I was unfortunately unable to remain long enough at the meeting to put the question at the only right time for it; but another Fellow informs me that he put the question, and that the President, the head of this very dubious movement, declined to answer it."

The facts are, however, as follows:—

Dr. William Robertson, Medical Registrar for Scotland, put into my hands the correspondence between the Southampton gentlemen and Dr. Hawkins; and then, without any further notice, asked, on behalf of Dr. Christison, whether it was my opinion that ungraduated Licentiates of a College of Physicians were legally entitled to be called Doctors? My answer was that I was not a lawyer, and could not therefore answer a question on a point of law.

I think you will agree with me, that this does not justify Dr. Christison's report; and I think many of the readers of the correspondence will think that it would have been quite as well had some of their authors been less forward to proffer their *dicta* in the matter.

I am, &c.

ALEXANDER WOOD, M.D.

President Royal Coll. Physicians of Edinburgh.

July 13, 1859.

[To the Editor of the Medical Times and Gazette.]

SIR,—You hit the right point of objection to the proceedings of the Edinburgh College. This College is licensing men without Medical examination, who have had no Medical test proposed to them by any corporate body previously, and who are notoriously and avowedly practising as Apothecaries. Many stupid persons who have crammed, so as to obtain admission to the College of Surgeons, but yet who have shrunk from a more general examination, often because they have not had a literary education enabling them even to pass the trifling Latin examination of the Hall, are now buying the Edinburgh licence, calling themselves "Physicians," and proposing to tack M.D. to their names. Can anything be conceived more likely to bring the Profession into contempt—the Doctorate at any rate? Pray go on exposing this ill-advised proceeding.

The Edinburgh men lay great stress upon testimonials obtained from men of eminence, and so on. Why, it is notorious that they can rarely be refused, especially in the country. If some country Surgeon or Apothecary, of fair moral character and professional industry,—one, moreover, who sends me patients, and causes me to be called in to distant and consequently lucrative cases applies to me for a testimonial,—can I very well make an enemy of him? And should I not do so by refusing to give him a testimonial? But, in fact, I have given my testimony under these circumstances, when its object was concealed from me. *Ex uno disce omnes.*

There has been a great deal of nonsense talked about the "Doctorate by courtesy," as belonging to ungraduated licentiates. Why, Surgeons, apothecaries, cow-doctors and druggists are by classes courteously called "Doctor." But have they a title to it? Heretofore, the Profession have courteously allowed the designate of Dr. to ungraduated Physicians, because they left the ranks of general practice and comprised themselves as purely professional men, excluding apothecaryism; but they were no more Doctors, in fact, than the so-addressed prescribing druggist. Now, will, or ought the Profession to concede Dr. to General Practitioners because they have bought this Edinburgh licence—holding as many of them do, a very low rank as General Practitioners? In the case of graduates there is no help for it, however desirable it should be that the degree should symbolise, as it once did, a *status* in style of practice; and an M.D. is a Dr., even if he be a grocer, and can legally affix the letters of prestige to his name.

Surely the Medical Council will take this matter up; or where is their function of elevating the qualification and defining its significance?

If the Edinburgh argument were good, and were practically carried out by the twenty other bodies, what a *reductio ad absurdum* it would constitute! I am, &c.,

Manchester, June, 1859.

AN M.D.

[The above remarks from a valued Correspondent deserve serious consideration. The character of the licence which is now being distributed on the widest scale among English Practitioners of Medicine, must sooner or later be canvassed. This is inevitable. We will here only mention one particular of the kind. At present, Licentiates of the Colleges of Physicians of London or Edinburgh are admissible as Candidates for the Physicianship of most of our great public charities; but we need hardly say that these laws will now have to undergo revision. We cannot doubt for a moment but that in future Licentiates of the Royal College of Physicians of Edinburgh will be proclaimed ineligible for those appointments. The reasons are obvious.—ED.]

[To the Editor of the Medical Times and Gazette.]

SIR,—I am induced to trouble you with a few thoughts on the question, "Who can assume the title of Doctor?" by the different view of the subject which I take from that advocated in your journal, while I doubt not that you are quite willing to give insertion to a fair and full discussion of it.

It appears to me that the recent regulations of the Edinburgh College of Physicians have (and I admit not without good reason) created much irritation upon this subject, and that the result has been, as is too often the case, a disposition to act hastily and to deal unfairly by those whose position, though apparently similar, is in many respects totally different from that of the newly-admitted Licentiates of that College.

I am aware that you have, for a considerable time, expressed your present opinions with regard to the title of Doctor; but I believe that they are not general, and that they would have met with but little support but for the ill-advised step taken by the Edinburgh College.

However, I wish to deal now solely with the claims of the non-graduated Licentiates of the London College to assume the title of Doctor (not of course of M.D.), and I would look at it under a threefold aspect—as regards usage, fairness and analogy.

As regards usage, there needs not much argument. The title has been given to, and assumed by such Licentiates for very many years, without dispute or gainsaying, up to the

time of the passing of the recent Medical Act, with the sole exception, as far as I am aware, of an occasional article, and of one memorable letter in your journal.

Then, as regards fairness. It cannot be denied that to obtain the privilege of assuming the title of Doctor as the only diagnostic sign in the public eye of the status of a Physician, has been a very influential motive with those who, not being Graduates, sought to enter the portals of the College of Physicians either as Licentiates or Extra-Licentiates; and let it be remembered also, that until last year, that learned body claimed to be the only one which could give a legal right to practise as a Physician in England, and that to those who were admitted the very title under dispute was at once given both orally and by letter by Dr. Hawkins who now takes on himself the responsibility of withholding it (whether authoritatively or not remains to be seen), who was then the Registrar, and the exponent of course of the laws and practice of the College. If I, and other gentlemen similarly situated, are now to be denied our customary appellation, how are we authorised to practise by a body *still* at the head of British Physicians, to be distinguished, so as to uphold our just claim? The prefix of "Physician," is uncouth, unusual, and, if assumed, it would add one more to the already too numerous sections in our Profession, and might, by the way, lead to some practical inconvenience to those gentlemen who so exclusively vaunt their claims as M.D.'s, but are not strictly Physicians.

I maintain that in the public mind in England, the appellation "Doctor," conveys practically, and almost universally, the idea of a Physician, irrespectively of any distinct association with a University; (although I am aware that the common phrase, "he took his degree," may be cited against me;) and I have considerable doubts, *pæce* Dr. Hawkins, whether the clause of the Medical Act affords any valid objection to its adoption in that sense.

Lastly, as regards analogy. I will not dwell on what has already been adduced, and not yet answered, the example of the taking and general recognition, of the title of Lord by the younger sons of Dukes and Marquises; but, descending to the learned professions from these magnates, I would briefly refer to two somewhat parallel cases, viz. that of attorneys called to the bar, or barristers admitted as such, who have not been educated at a University. In neither case is there any kind of distinction from their brethren in the designation of these gentlemen—"Barrister at Law" is the common and recognised title of all.

Then, again, many "literate persons" are admitted to Holy Orders, who have not been educated, or at least have not graduated, at a University. The Rev. Mr. So-and-so, is the common appellation of all, and given, as far as appears, ungrudgingly and universally.

Of course, none have the right, and few will have the inclination, to attach M.D. to their names hereafter, who are not *bonâ fide* Doctors of Medicine; to such, being *by law* Physicians, I would suggest the simple expedient, where their duties require it, of attaching the abbreviation Med. (for Medicus) to their names; thus defining their position without any violation of law.

I hope that the Medical Council, at their meeting in August, will come to a calm and just conclusion on this subject, in the shape of a recommendation, at all events, if they do not feel at liberty to deal authoritatively with it.

It must be borne in mind that there are Fellows of the London College, as well as many Members, to whom the above remarks apply—men who have bound themselves to relinquish Pharmacy, and of whom the greater part are strictly and solely Physicians, and that to such the attempt to withdraw a designation which has long been associated with their honourable, and, in many instances, hardly-won position, is not only irritating, but, as I contend, unjust.

I am, &c.,

A NON-GRADUATED LICENTiate OF THE LONDON COLLEGE OF PHYSICIANS.

P.S. Since writing the foregoing remarks I have read the Southampton correspondence. It does not appear to me to weaken my arguments in behalf of the non-graduated Licentiate of the London College. These have *all* passed an examination before obtaining their licence to practise as *Physicians*, and many have held the title of Doctor for years under the sanction of their College (a sanction, as is truly said by Dr. Hawkins, "of no slight authority") and also "by a cour-

tesy" which is "customary, and is in fact recommended by long prescription and usage."

Dr. Christison is evidently unacquainted with the English view of the subject.

LETTER FROM JOHN E. SMYTH, B.A. L.R.C.P.

[To the Editor of the Medical Times and Gazette.]

"Of things once received and confirmed by use, long usage is a law sufficient."—Hooker.

SIR,—By a correspondence published in your journal of last week, I find that Dr. Hawkins has been induced by the representations of some gentlemen in Southampton, to infringe a long-established act of courtesy always observed towards non-graduated Physicians of the United Kingdom. He appears, from what he states, to have acted in this matter reluctantly; but how far he is justified in doing so without the sanction of the Medical Council is another question. At all events, I would suggest that to place all parties on an equal footing, the undiplomatized graduate should renounce all claim to the title of Physician. For, I think, that the Licentiates might, with equal reason, demand exclusive right to that title, as the M.D.'s do to that of Doctor.

Will your Southampton correspondents consent to this proposal? Or do they aim at the double title with the single qualification? To be consistent they can hardly withhold assent. However, I shall, meantime, inform them that the non-graduated Physician is not legally disqualified from assuming the title of Doctor by the words of the Act itself. "Any name, title, addition, or description, implying that he is registered under this Act, or recognised by law as a Physician or Surgeon, or Licentiate in Medicine and Surgery, or a Practitioner of Medicine, or an Apothecary, etc., etc." No mention whatever being made of the title of Doctor of Medicine in the concluding part of this section; allow me also to add, that the attempt to make a distinction between the London and Edinburgh Licentiates falls to the ground when it is borne in mind that the Medical Act gives equal rights and privileges to the members of both Colleges. The same Act also converts Scotch Graduates into legal Practitioners of Medicine in England—what they were not twelve months ago. Assuredly your correspondents ought to be satisfied with this boon, and not be so churlish towards their neighbours as not to allow them a little advantage also. They may rest assured that the Licentiates of the Colleges of Physicians of London, Edinburgh, and Dublin, whether Graduates or not, will continue to use a title which has been established by the usage of centuries, and is plainly sanctioned by law.

I am, &c.,

JNO. E. SMYTH, B.A., L.R.C.P. Edin.

2, China-terrace, Lambeth,
July 10, 1859.

[To the Editor of the Medical Times and Gazette.]

SIR,—The assumption in England by Licentiates of the Edinburgh College of Physicians of the title "Doctor," cannot be sustained upon the ground either of usage, custom, or legal authority. Until the recent Medical Act, there could be no such usage in England, seeing the privilege to practise which the Edinburgh licence conferred on recipients of that honour was limited to the narrow boundaries defined in the College Charter; and although these limits have been now expanded or enlarged, so as to be co-extensive with all parts of Her Majesty's dominions, still the new Act has not otherwise altered or modified any existing professional privileges and qualifications.

Prior to the quoted Act of last year, the right to confer the designation "Doctor" was by law exclusively vested in Universities. In ancient times, Bede is said to have really been the first Doctor at Cambridge, and John de Beverley at Oxford, where the latter died, A.D. 721. The learned Spelman, however, contends, that "Doctor" was not the name of any title or degree throughout England till the reign of King John; that is, about the year 1207. Again: Linacre was born in 1460, chosen Fellow of All Souls, Oxford, in 1484, took the degree of M.D., at Padua, and afterwards, on returning to England, became an incorporated M.D. at Oxford.

The College of Physicians of London was founded originally in the tenth year of Henry VIII., and in its

Charter Linacre with his fellows are all designated "Doctors," which title they must have obtained elsewhere. This shows clearly and indisputably that Universities alone exercised the privilege of conferring this title previous to the incorporation of the London College of Physicians. The latter body has never claimed that privilege; while the Edinburgh College, of subsequent creation, it is well known, puts forward no claim of that description. The Licentiates of the latter Corporation, then cannot rely on any usage in the kingdom of Scotland; since, until within a few weeks ago, no such anomalous Medical Practitioner was created north of the Tweed, like an Ungraduated Licentiate of the Edinburgh College of Physicians. There was thus no usage whatever; no courtesy could ever therefore be demanded or assumed. Throughout England and Wales, but for the Medical Act, a Licentiate of the College of Physicians of Edinburgh could not, legally, practise his profession; consequently, neither usage nor courtesy can support the claim now made in England by Scotch Licentiates. Holders of the Medical licence in question, to justify themselves in henceforth assuming the much-desired title of "Doctor," ought to apply first to some University, and there try to obtain the degree of M.D., which must be regularly conferred, and with due formalities. It may be contended that the recent Act of 1858, virtually prevents no man from calling others or himself "Doctor," "Accoucheur," and so forth, provided he does not actually designate himself "Doctor of MEDICINE." But that legislative measure cannot set aside, or in any way supersede the common law of England, which may perhaps be found sufficiently stringent to bring within its gripe every person surreptitiously assuming a title which he cannot legally justify or support. This result I think will prove to be the case with Licentiates of every British College of Physicians who call themselves "Doctor" without any other document, warrant, or authority, than that which the specific licence to practice confers upon a recipient therein named.

I am, &c.,

A BIT OF A LAWYER.

London, July 12, 1859.

DILATATION BY FLUID PRESSURE IN OBSTETRIC SURGERY.

LETTER FROM DR. JAMES ARNOTT.

[To the Editor of the Medical Times and Gazette.]

SIR,—It is much to be regretted that those who have been prosecuting the enquiry, to what extent dilatations by the pressure of a fluid may be useful as a therapeutical agent in midwifery, and who have already favoured the Profession by the publication of practical details on the subject, should have their attention drawn aside from this important investigation by a profitless controversy about the origin of the practice. Perhaps the relation of the following circumstance may put an end to the correspondence on this subject in your journal:—

In an appendix to the second edition of a Treatise on Stricture of the Urethra, published in 1840, and ten years before the Memoir alluded to in the controversy was read at the French Academy, I strongly recommended fluid pressure as a means of facilitating childbirth in certain cases, and have adverted to it on various subsequent occasions. In a paper on Therapeutical Enquiry, inserted in the *Medical Times and Gazette* for 1845 and 1846, it is mentioned with numerous other practical suggestions; and in an appendix to this paper, published separately, the "application of a fluid pressure for the purpose of dilatation, or for checking hæmorrhage," is again and more fully described. Nor was this only a suggestion. As far as my limited opportunities permitted, I proved its value by experience. In the preface to an Essay on the Treatment of Headache and Neuralgia by Congelation, published in 1849, I speak of this experience, and compare the expedient, as respects one of its uses, with the action of the air-tractor recommended by Dr. Simpson, remarking that it "effects the principal purpose of the forceps with greater safety in another way, namely, by removing the obstacle to extrusion, instead of augmenting the extruding force."

I have no doubt that this mode of dilatation will be as useful in midwifery as it has proved in the treatment of stricture and stone; and I look forward with pleasure to Dr. Keiller's promised account of its employment in the Edinburgh

Hospital. The ease with which caoutchouc is now fashioned into bags of various shapes and sizes will facilitate the general adoption of the measure, but much will still depend upon the Accoucheur's ingenuity in adapting the principle to particular cases, or for the fulfilment of particular purposes. For it must be remembered, that it is not merely the application of a good principle that will effect its purpose, but the *proper* application of it.

London, July 9th, 1859.

I am, &c.
JAMES ARNOTT.

THE WESTMINSTER OPHTHALMIC HOSPITAL.

[To the Editor of the Medical Times and Gazette.]

SIR,—I copied from a report in the *Times* newspaper of a few days ago, a statement of the results of operations for cataract at the Westminster Ophthalmic Hospital. It was to the effect that during the previous year 106 cases had been treated by operation. Of these, the cataract was stated to have been of the hard kind in 57, and of the soft in 49 instances out of the whole number: 97 were stated to have been completely successful, and 8 partially so. In but one instance out of the 106 did the report admit that the eye had been lost, and in that "sudden illness afterwards" was assigned by way of explaining the bad result.

Will any of the surgeons of the Hospital referred to be good enough to inform the Profession whether the above statement is authentic, and put forward with the sanction of the Medical staff?

If it is acknowledged, I shall have some surgical questions to put respecting its facts; and if it is disclaimed, I shall have some ethical comments to make respecting its publication.

You, Sir, have conferred such great services upon the profession in the matter of operation statistics, that I make no apology for asking a place for this note in your pages.

I am, &c.

July 9th.

A. O. L.

USES OF COLLODION.

LETTER FROM MR. THOS. P. O'DONOVAN.

[To the Editor of the Medical Times and Gazette.]

SIR,—The perusal of Dr. Behrend's paper, on the use of Collodion in Spina Bifida, in your journal, led me to think that the following cases, exemplifying the use of collodion in chronic inflammation of the testicle, might not be uninteresting:—

Case 1.—A. B., labourer, Mayfield, Sussex, Nov. 1856; came under my treatment for chronic inflammation of the testicle, the residue of previous acute inflammation, the result of over exercise during gonorrhœa.

Pressure producing neither pain nor tenderness of the enlarged testis. The scrotum of the affected side was painted with collodion, in two or three layers, each layer being allowed to dry before the next was applied. The result was instantaneous corrugation, and vermicular movement of the scrotum, and second by second the diminution of the testis, till in a few moments it had attained its natural size. The collodion was allowed to dry. A suspensory bandage was applied. The man walked home. For two or three days he came to the surgery; the testis still retained its normal size. The collodion was applied two or three times, for caution's sake, and on the fourth day the patient was discharged cured.

Case 2.—B. C. "Ran against a post," at least, so he said, and afterwards had acute and then chronic inflammation of the testicle. The collodion was applied, but I believe it was applied two days too soon, for there was no rapid effect in this case, save increase of pain. For two or three days there was little or no improvement. On the tenth day the man was well.

If this plan be found equally efficacious in the hands of others, I think its advantages over adhesive plaster will be found too obvious to need comment.

University College, London,

THOS. P. O'DONOVAN.

A remarkable case of suicide occurred in Dumfries Gaol. A boy, aged ten, to escape forty days' duration in prison, committed an act of self-destruction.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 28, 1859.

F. C. SKEY, Esq. President, in the Chair.

A paper by THEOPHILUS THOMPSON, Esq. M.D., F.R.S. was read on—

OBSERVATIONS ON THE MEDICAL ADMINISTRATION OF OZONIZED OILS.

The author, after some general remarks on the properties of ozone, describes the results obtained from its administration in association with oils; the oils being ozonized by exposure for a considerable time to the direct rays of the sun, after previous saturation with oxygen gas, according to the process adopted by Mr. Dugald Campbell. The cases of fourteen consumptive patients to whom the ozonized oils were given are detailed; and the principal facts noted are also appended in a tabular form. The conclusion to which these experiments point is, that the administration of ozonized oils has a remarkable tendency to reduce the frequency of the pulse. Of the fourteen patients whose cases are detailed in this communication, there are only two in whom no such effect was observed; and although in a few instances the effect may have seemed insignificant or transient, in the larger proportion it was very considerable, and must be attributed to the ozone rather than to the oil, since it was repeatedly manifested in patients who had taken cod-liver and other oils without any reduction, or even with an acceleration, of the pulse; and further, the effect on the pulse was nearly as distinct when the ozone was associated with the oil of the cocoanut, or of the sunflower, as with that of the cod liver. This circumstance is the more significant, since the administration of sunflower oil without ozone has not appeared to the author to manifest any important remedial power. The reduction of pulse was usually observed in two or three days, and often continued progressive. A reduction of twenty beats was observed in certain cases to occur respectively in two, three, four, and six days; in other instances a reduction was noted of twenty-four pulsations in fourteen days, thirty-four in thirteen, thirty-six in twenty-two, forty in eleven. In one patient the pulse fell as low as 60—probably considerably below the natural standard; but in most of the favourable instances the reduction stopped when that standard was obtained. The apparent effect of the remedy is one which, prior to experiment, the author would not have anticipated. No other obvious result was noticed, excepting a general improvement in the patient's condition. In some of the patients the use of simple and of ozonized oils was alternated. In one case the alternation was made three times, and the result was in each interchange of treatment so direct and remarkable as to make that particular example equivalent in force to three experiments. In addition to the patients under his own observation, the author refers to four instances noted by Dr. Scott Alison, who obligingly pursued the investigation during Dr. Thompson's absence from the Hospital. In these four cases the disease was in the third stage. In two, a remarkable reduction in the rapidity of the pulse, amounting to about twenty beats, occurred under the use of the ozonized oil, while the improvement induced could not be referred to any other cause. Dr. Alison remarks, "I attach some value to this observation; for I prescribed the oil totally divested of all prejudice in its favour, and I have always been reluctant on imperfect grounds to refer results to the operation of medicines. If ozonized oil can reduce the rapidity of the circulation—a feature of great prominence in phthisis,—this remedy possesses a most valuable property, rendered still more valuable by its contributing at the same time to improve the general health." The author mentions having used ozonized oil of turpentine with marked and prompt advantage in some cases of hæmoptysis, but has not sufficiently repeated the experiment to feel entitled to express an opinion as to its remedial superiority over ordinary turpentine. He adds that, should more

extended observation establish for ozonized oil the property indicated by these experiments, it will prove a valuable addition to our list of remedies, especially in consumption (which is a disease peculiarly characterised by hurried action); but not, perhaps, exclusively in this disorder, since there are other morbid conditions in the treatment of which it is very important to lower the pulse without reducing constitutional strength.

A paper by JOHN W. OGLE, M.D. was also read on

A CASE OF PARALYSIS,

AS TO VOLUNTARY MOTOR POWER, OF ONE-HALF OF THE BODY, ATTENDED BY CONTRACTILE HYPERÆSTHESIA ON THE CORRESPONDING SIDE OF THE FACE, AS THE RESULT OF COMPRESSION OF CERTAIN LATERAL PARTS OF THE BRAIN FROM AN INTRA-CRANIAL ANEURISM; WITH OBSERVATIONS UPON "INDUCED" PARALYSIS.

In this communication, after prefatory allusions to the general subject of the production of motor paralysis from injury or disease of the corresponding side of the brain, in contradistinction to a crossed paralysis from an affection of the opposite side of the brain, the author goes on to relate a case of aneurism of the left anterior cerebellar artery, so placed as directly to press upon the anterior surface of the middle crus cerebelli on the left side, and implicating, although to a very slight degree, the superficial part of the neighbouring pons Varolii, etc. The apparent root of the fifth cranial nerve, on the same side, was also pressed upon by the aneurism; and the seventh nerve, in its forward course towards its exit from the cranium was greatly pressed upon. The other cranial nerves, excepting the optic nerves, were unaffected. The specimen was removed from the body of a middle-aged woman, who had been an epileptic, and had lost her sight for five years. She also suffered from partial loss of muscular power on the left side of the body, and contractile hyperæsthesia of the skin of the left side of the face and head; and impairment of the senses of smell, taste, and hearing on the left side. The chief point of interest in the case was the existence of paralysis, more or less incomplete, of the muscles of the limbs on the side of the body corresponding with the cerebral pressure; but besides affording an illustration of the existence of such an anomalous form of hemiplegia, the case is exceedingly interesting as being an instance in evidence of the statement lately established by Dr. Brown-Séquard, that when pressure is made on the anterior surface of one of the crura cerebelli, without materially injuring neighbouring structures, the paralysis produced (if any be caused) will be almost invariably of the muscles on the corresponding side of the body. Dr. Ogle points out at length the coincidence, in his case, between the interference with the sensibility of the skin, the power of the moving muscles of the jaw, and the sense of taste, on the one hand, and the pressure upon the fifth cranial nerve, on the other; and again, between the deafness and facial paralysis, and the injury to the seventh pair of nerves. The author considers, to some extent, the probable causation of the paralysis existing on the same side of the body as the cerebral lesion—a form which Brown-Séquard looks upon as being owing, not to any absence of action, but to some kind of irritation, or "excess of action," reflected, as he states, to some central or conducting part of the nervous system from the particular part primarily affected. Dr. Ogle, while recognising this method of explanation, ventured to suggest the term "induced" paralysis as being one more clearly conveying the meaning intended to be given by the word, and as being less likely to be misunderstood than the expression "sympathetic" or "reflected" paralysis, which Dr. Brown-Séquard had applied to this form of paralysis.

ROYAL SOCIETY OF LONDON.

MAY 26, 1859.

Sir B. BRODIE, Bart. in the Chair.

A paper by A. T. H. WATERS, Esq. of Liverpool, was read, on THE STRUCTURE OF THE ULTIMATE AIR-TUBES, AND THE DISTRIBUTION OF THE BLOOD-VESSELS, OF THE HUMAN LUNG.

The bronchial tubes terminate in a dilatation, into which open a number of cavities, to which various names have been

given, but which the author proposes to call air-sacs. The air-sacs connected with a terminal bronchial twig, with their vessels, etc. constitute a lobulette. The lobulette consists of from six to twelve air-sacs; the latter are somewhat elongated cavities, lying side by side in the lobulette, and separated from each other by thin walls; in shape they are polygonal from mutual pressure of their parietes. They all communicate with the dilated extremity of the bronchial tube, which forms the common mouth or centre of all the sacs; they have no lateral orifices of communication with each other; they often divide or give off other sacs; the air-sacs of one lobulette do not communicate with those of another. The walls of the air-sacs are covered by a number of small, shallow, cup-like depressions, separated from each other by partial septa. These depressions, or alveoli, are very numerous; their number varies in different air sacs, from eight to twenty. The lobullettes are supported externally by the pleura, but within the lung, in part by the bronchial tubes and bloodvessels. The membrane forming the walls of the air sacs in a lung inflated and dried is very transparent; it constitutes, by its projection towards the centre of the sacs, the septa of the alveoli. Each lobulette is distinct and separate from those which surround it. The separation may be sometimes seen in the inflated infants' lung, but the observation of the foetal lung affords the best proof of it. The author alluded to investigations he had made on the lungs of foetuses which confirmed the view he had taken of the arrangement of the ultimate pulmonary tissue, and of the separation between the lobullettes. The air-sacs are fully formed before birth, and each lobulette is seen as a little red body attached to an air tube. By a partial or complete inflation of the foetal lung, the arrangement of the air-sacs may be distinctly made out. The bronchial tubes at their termination have a special character. A number of alveoli, like those of the air-sacs, is found in their walls. They are best seen in the lungs of some of the lower animals, as the cat. The author has found them in the infant in the last divisions of the bronchial tubes and their dilated extremity; in the adult, only in the dilated extremity. They seem to become obliterated with advancing age. Their existence was first pointed out by Rossignol. The bloodvessels of the lungs: The pulmonary plexus is situated in the walls of the air-sacs; when formed it maintains a tolerably uniform diameter throughout; the spaces between the vessels, in an injected and inflated preparation, are somewhat larger than the vessels themselves. The branches of the pulmonary artery do not anastomose till they reach the termination of the bronchial tubes; they anastomose freely in the air-sacs. The author believes that the vessels of one lobulette do not anastomose with those of another; that, consequently, in the adjoining walls of two lobullettes two layers of capillaries lie side by side, and therefore in such situations the blood is not fully exposed to the air on both sides. The radicles of the pulmonary veins issue from the periphery of the lobullettes, and forming larger vessels, run in the interlobular spaces to the root of the lung. After briefly alluding to the general opinion of the distribution, etc. of the bronchial vessels, the author described the results of his own injections. Injection of the pulmonary artery, so as to fill the plexus, but not the veins, does not inject the vessels of the bronchial tubes; but if the veins are filled, the bronchial tubes become partially injected. Injection of the pulmonary veins, whether the plexus be well filled or not, always injects the bronchial tubes. Injection of a bronchial artery when fairly within the lung, produces injection of the bronchial tubes, and the fluid returns by the pulmonary veins. It is difficult, in man, to fill the vessels of the extreme bronchial tubes through the bronchial artery. The bronchial veins: The author has never been able to find the so-called deep bronchial veins as venæ-comites of the arteries. The only veins he has found, have been one or two small ones, usually one, at the root of each lung, which, on being injected, were found to terminate in the structures about the root of the lung, and not to accompany the arteries within the lung. From careful injection and repeated examination of a large number of specimens, both of man and the lower animals, the author draws the following conclusions of the distribution and termination of the bronchial vessels. The bronchial arteries are distributed to the bronchi, bronchial glands, bronchial tubes, etc.—both their mucous membrane and deeper parts—the bloodvessels and areolar tissue of the lungs; and they terminate, 1st, those about the root of the lung, in

the bronchial veins; 2nd, those within the lung, in the pulmonary veins. The bronchial arteries do not establish any communication with the pulmonary arteries. The author concluded by alluding to the views of previous observers.

PARLIAMENTARY INTELLIGENCE.

MEDICAL CHARITIES AMENDMENT ACT.—Mr. Dawson asked the Chief Secretary for Ireland whether it was the intention of the Government to introduce a Medical Charities Amendment Act during the present session; and, if so, when such measure would be laid upon the table of the House. Mr. Cardwell said that, considering a measure of this kind had been discussed for two or three years past, he did not think there was any probability of passing a measure during the present session.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations in anatomy and physiology on the 5th, 6th, 8th, and 9th, inst., will be admitted to the pass examination for membership when qualified—viz., Messrs. Frederick Agar, Frederick John Withers, R. Orton, G. Orton, Brice Smyth, John Gay French, Thomas Henry Thomson, Thomas Achmuty Keating, James Robert Gausson, John Livingstone Power, Thomas Alexander O'Flaherty, and William Cheetham, of the Dublin Schools; George John Bennett, Herbert Evans, Christopher Blencowe Noble Dunn, William Holmes Walker, John Sides, Davies, Duncan Parker, Richard Wagstaff Smith, Frederick Eldershaw, Benjamin Harris, and Branthwayte Beever Ford, of St. Bartholomew's Hospital; Frederick Beaufort Scott, John Richard Harding, Athendore de Negri, Samuel Lloyd, George Styck Eadson, Richard Lewis Shore, Robert Dunlop, Edward Mahony, and Thomas Bower Smith, of University College; Thomas Annandale, Stephen James Meintjes, John De Smidt, Philip Edward Miall, Mority Stern, William Cummins Piggott, John Broster, and George Carr Dunn, of the Edinburgh Schools; Arthur Heslop, Thomas Foster, Kenrick Bold Williams, Henry John Yeld, and Felix William Isherwood, of Glasgow; Arthur Edwin Hutchinson Trotter, Thomas Charles White, Henry Joseph Altmann, and Thomas Sheldon Green, of King's College; Samuel Alexander M'Gowan, David Moore, Andrew Robinson, and James Minniece, of Belfast; William James Mallart and Charles Henry Stone, of Manchester; Anthony Cornish Tucker and James Bradford Bell, of the Middlesex Hospital; Edward Arthur Howsin and Charles Steele, of Bristol; Henry Rickard and Frederick Taylor, of Charing-cross Hospital; John Symons and William Terry, of Guy's Hospital; Evan Thompson and John Ca rick Smith, of Newcastle-on-Tyne; Robert Williams, Liverpool; Alfred Johnson, York; Richard Ireland, Galway; John March, Westminster Hospital; John Blackburn, Sheffield; Francis Morris Foster, of Hull; James Joseph Foley, of Cork; and Clement Winstanley, of St. Thomas's Hospital.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, July 7, 1859:—

MAYOR, THOMAS ORLANDO, Bristol.

SMITHWAITE, GEORGE, Hargreaves street, Burnley.

WATERS, JOHN, 20, Great Russell-street.

The following gentleman also, on the same day, passed his first examination:—

MERCER, JOHN THOMAS, Leicester.

DEATHS.

BENNETT.—Thomas Wainwright Bennett, Staff Assistant-Surgeon, died on the 28th of June at Lymm, Cheshire.

COOKE.—Mr. L. R. Cooke, of Charlwood-street, Belgrave-road, late House-Surgeon to the Samaritan Hospital, has been elected Assistant-Surgeon to the Royal Pimlico Dispensary.

FABRIZI.—Dr. P. Fabrizio, known as the author of several works on different points of Surgery, died at Nice, on May 5, 1859. This gentleman visited many of our Hospitals last year.

WINTERBOTTOM.—On the 8th inst. at Westoe, near Shields, Dr. Winterbottom, in the 95th year of his age. He was the oldest Practitioner in the new Medical Register—author of "Winterbottom on Hot Climates." He resided several years in Sierra Leone, but latterly in Shields. He has left the greater part of his fortune to found a School of Navigation for young Tyne seamen.

"PHRENOLOGY is one of the three great scientific mystifications of the nineteenth century: the other two are animal magnetism and homeopathy."—*Rochoux*.

In accordance with the resolution passed at the Comitia Majora, on July 25th, a *soirée* will be held at the College of Physicians, on Wednesday, August 3, at nine o'clock p.m.

A GOOD EXAMPLE.—The Duke of Northumberland has just sent a thousand bottles of old sherry, thirty years in bottle, to the Westminster Hospital, for the use of the patients.

"ANIMALS," says M. Flourens, "perceive, think, and reflect; but man is the only one of created beings who possesses the attribute of perceiving that he perceives, of knowing that he knows, and of thinking that he thinks."

PRIZE QUESTION.—THE IMPERIAL SOCIETY OF MEDICINE OF BORDEAUX offers a prize of 300 francs for the best essay on the "Prophylaxis of Tuberculosis." The memoirs, written in French or English, must be forwarded to M. Dégrange, Secrétaire, rue St. Catherine, 25, before March 15.

PARIS SURGICAL SOCIETY.—The following officers have been chosen for the session 1859-60. *President*, M. Marjolin; *Vice-President*, Mr. Laborie; *Secretaries*, MM. Depaul and Legouest; *Treasurer*, M. Houel; *Librarian*, M. Verneuil; *Publication Committee*, MM. Laborie, Morel-Lovallée and Follin.

THE COLLEGE OF SURGEONS.—We understand that at the recent important sale at the Mart of the Estates of the late Joseph Cantwell, Esq., by Messrs. Edwin Fox and Bousfield, the extensive premises No. 43, Lincoln's Inn Fields, and No. 6, Portugal-street, in the rear, were purchased by the Royal College of Surgeons. The tenure of the property is peculiar, being held for 875 years unexpired, at a peppercorn rent.

THE MINISTER of Agriculture in France has decided that no proprietor shall henceforth be indemnified for the loss of his cattle by epidemic diseases, unless he produce a certificate from the mayor that his cattle have died under the due authority of an authorised veterinary doctor! Has it never occurred to the Minister, that according to logic, what is good for the beast in this respect must also be good for the man?

MR. HOME, the famous medium, has lately rather put his foot into it at Paris. At one of his *séances* one of the guests, a particularly active individual, made a sudden grab at the spirit, which was tickling his leg, and, behold! he found Mr. Home's foot in his hand. On another occasion, a child's glove was found lying on the floor when the furniture was being put to rights after the *séance*.

SYMPTOMS OF APOPLEXY OF THE CEREBELLUM according to M. Hillairet. Vomiting, rare in apoplexy of the cerebellum, is constantly present in cerebellar apoplexy: there is also no loss of sensation; the intelligence remains perfect, although the speech may be difficult or impossible; there is absence of perfect hemiplegia, an absence of paralysis, and no loss of sensibility; and lastly, the attention of the patient can be readily excited.

THE AUSTRIAN ARMY'S SICK AND WOUNDED.—The greatest possible exertions are being made for the relief of the sick and wounded soldiers, and the "Patriotic Association" has now engaged and sent to the seat of war no fewer than 220 Physicians and Surgeons. All the slightly wounded soldiers have been sent back to Trieste, Laibach, Graz, etc., and preparations made at Mantua, Verona, Vicenza, Padua, etc., for the reception of 30,000 patients.

ECHO OF THE WAR IN THE FRENCH ACADEMY.—A bronzed aluminum pistol, amongst other aluminum objects of

art, has been presented to the Academy of Sciences by M. Dumas on the part of M. Christophe. This composition is remarkable for its extreme tenacity. "M. Christophe begs the Academy will back his request made to the War Minister, that he may be permitted to make at his own expense a piece of artillery." He is certain that this metal is far superior to ordinary bronze.

TESTIMONIAL TO DR. FRANCIS HAWKINS.—A portrait of the above-named gentleman has just been placed, by subscription among the former pupils of the Middlesex Hospital, in the Board-room of that institution, in which he occupied the post of Physician for a period of thirty-five years, and from which he has recently retired on account of his appointment to the office of Registrar to the Medical Council. The artist, who has very successfully portrayed the worthy Doctor's features, is Mr. J. Edgar Williams.

CUVIER believed in the immutability of species in animals; but he made an exception in the case of man. M. Pouchet thinks that in so doing Cuvier taught what he did not believe; for according to M. Geoffrey Saint Hilaire "Cuvier had a great respect for political conveniences, and was filled with all sorts of wise reserves affecting the future of societies, and therefore felt that the new revelations which had arisen out of the bosom of the earth, ought not to be let loose against and injure with a hostile malignity the venerable and ancient revelations of the sacred volumes." Such a sentiment is a praise to the man, adds M. Pouchet, but is blameable in the systematic writer.

At the Torbay Infirmary one hundred and seventy patients have raised among themselves subscriptions from a penny to a shilling, and therewith purchased a handsomely-bound copy of Bagster's Comprehensive Bible, with the following printed inside the cover:—"Presented to William Wilking Stabb, on his retirement from the appointment of House-Surgeon to the Torbay Infirmary and Dispensary, by a number of the poor patients who, having experienced the benefits of his professional ability, desire to show their gratitude for the kindness, care, and sympathy at all times evinced by him. 1859." The governors have presented a silver teapot, and the board of management a silver milk-jug to Mr. Stabb.

UNIVERSITY OF DUBLIN.—Trinity College School of Medicine—Prizes in Practical Chemistry.—1st. Mr. Henry Steward Lodge, £3 3s.; 2nd. Mr. Henry Fitzsimon, £2 2s. At the Summer Commencements, held on Wednesday, July 6th, the following degrees were conferred: M.C. (*Magister Chirurgiæ*).—Jacobus Gul. Cusack (stip. cond.) (a); Robertus Gul. Smith (stip. cond.); Benjamin G. McDowel (stip. cond.); Edvardus H. Bennett, M.B.—Edvardus H. Bennett, Georgius B. De Landre, Gilbertus de P. Nicholson, Leonardus Kidd (*antea per diploma*); Johannes Campbell, Patricius C. Baxter.

CANCER HOSPITAL.—On July 9th, the Annual Meeting of this Institution was held at the Offices in Piccadilly. Mr. Oliver Farrer in the chair. The Report of the Committee congratulated the Governors on the increase of the funds of the institution, and also its extended usefulness. The receipts from all sources had been £3603 15s. 9d., and the balances, after defraying all expenses, were £321 4s. 10d., with £1,700 stock. The new Hospital at Brompton was progressing satisfactorily, and would be opened early next year. The number of patients who had received the benefits of the charity was 2,803, being an increase of 538 over the number of the preceding year. The Report was adopted, and the numerous officers were thanked for their past services. The kindness and munificence of Miss Burdett Coutts were warmly appreciated, and a special vote of thanks was passed to Dr. Marsden, the founder.

WHY PHRENOLOGY HAS ITS PARTISANS AMONG CERTAIN LEARNED MEN.—"In the arts and letters, and in the minds which cultivate them (or have the seeming to do so) there are degrees and kinds. At the bottom, at the very foot of the scale, there is the Boulevard du Temple and the Cirque with their authors, their works, and their public. So likewise in the Sciences there is a public which is a crowd, and there are Savans which are a crowd also, who in matters of science understand and delight only in that which falls most grossly upon the senses; in ideas, which are only sentiments, and theories which are only mere colourings; in the place of

careful observation they place the most wretched empiricism, and substitute dreams for facts. For this sort of the public have been invented, almost from the commencement of the world, and have been renewed from age to age, under one name or other, all the false and mad sciences, of which phrenology closes the list."—*M. Lélut.*

RE-VACCINATION.—Dr. Laure, Surgeon-in-Chief of the Marine at Toulon, gives his experience on the subject of re-vaccination. In 1857 and 1858, 2995 re-vaccinations were practised in the division of the Navy at Toulon; and from these facts he derives the following conclusions:—1. The vaccine virus taken directly from the arm is incomparably more efficacious than that from the glass. 2. Vaccine taken from re-vaccinated adults is capable of producing excellent pustules, which are inoculable equally as the vaccine taken from children. 3. In adults, it is necessary to introduce the virus deeply, and not merely under the epidermis. 4. The practice of re-vaccination, ordered by the Government in the army and navy, is a measure of the highest importance, and its execution ought to be strictly carried out. 5. Those who have had small-pox should be re-vaccinated equally with the vaccinated. 6. The local phenomena resulting from the re-vaccination are very slight; but the individual should be kept from duty for a few days.

AN INCIDENT OF WAR.—A military Physician, who was taken prisoner by the French at Magenta, has addressed an extremely interesting letter to a colleague in Vienna. The writer of the letter, with several of his fellow-physicians, remained at Magenta after the retreat of the Austrian army in order to tend the wounded. As a measure of precaution a white flag was hoisted over the house which served as an infirmary, but still it was attacked by the Zouaves. Several of the patients were shot dead, and Dr. Forst, a regimental physician, was wounded while attending to a wounded Frenchman. The confusion which ensued was fearful. "Some poor wretches sought shelter in the cellar and garret, some attempted to kill themselves by knocking their heads violently against the wall, and others jumped out of the windows. I ran to one of the windows, and called out to the assailants that the house was full of wounded and helpless men. Their arms were clamorously demanded, and when they were surrendered, order was restored." The physician, who is now at Milan, says that the allies have an enormous number of wounded. He works from the morning till night in the hospital of St. Ambrogio, but he has not received one farthing for his trouble, although he has lost both baggage and money.

MORTALITY OF SOLDIERS.—M. Tholozan concludes a series of articles in the *Gazette Médicale* upon military mortality in the following terms:—"The most important conclusions to be drawn from our own observations, as well as from the works which have been published of late years relative to the hygiene, statistics and diseases of armies are the following: The considerable increase of deaths which afflict an army in the time of peace, is especially caused by pulmonary lesions of a peculiar character. These lesions are the effect of a special vitiation, a specific diathesis of the economy which results from the overcrowding, the agglomeration and the life in common incidental to barracks. Thus far, science has not been able to apprehend the differences which prevail between these conditions and those amidst which variola, rubeola, scarlatina, typhoid and typhus are developed. The means which are suitable for the prevention or diminution of these latter diseases are also wonderfully appropriate appliances for combatting the endemic phthisis of the army. If the opinion I here advance becomes confirmed, we must in future regard the phthisis of armies rather as a specific infectious disease than as an organic, diathetic, hereditary affection. Pathology enlightened by hygiene would thus modify one of its most absolute beliefs, and this reform, in its turn, would second and generalise one of the most important advances of hygiene."

OPIMUM IN FRANCE.—M. Roux, Professor of Botany at the Naval School of Rochefort, has just sent in an interesting paper to the Academy of Sciences on the cultivation of the poppy in France for the purpose of extracting opium. His first researches on this subject date from 1851, but were more especially continued by him during 1856, 1857, and 1858, on eight different kinds of poppy. His results are stated as follows:—1. The Indian poppy furnishes a considerable

(a) Stip. cond.—stipendiis condonatus—forgiven the fees.

quantity both of opium and seed; the cultivation of this vigorous species might be tried in those departments of France where the oil of the black garden poppy is a staple produce. The Indian poppy may be easily acclimatized in France. A quantity sown in October, 1857, has succeeded perfectly, and the young plants resisted a cold of 10 degrees centigrade (18 degrees below Fahrenheit's freezing point) in the following winter. This cold proved equally harmless to the white, black, and red species, which were sown about the same time. 2. The two latter produce the best opium, and their juice is much richer in morphine than is the case with the opiums of commerce. 3. A man can collect 100 grammes of opium in fifteen hours; and if women and children, who are so often in want of employment in the country districts, were employed on this task, the opium necessary for medical purposes might be entirely grown in France. 4. The growing of opium might become very profitable in France, where poppy-oil is manufactured to the amount of from 25,000,000*l.* to 30,000,000*l.*, and where it would, consequently, be easy to add a new branch to that trade by the extraction of opium; and it might even, in course of time, become an article of exportation. Home-grown opium has been tried, at M. Roux's request, by M. Duval, first chief Navy Surgeon at Brest, and found to answer very well, owing to the quantity of morphine it contains.

PLEURISY, BLEEDING, AND PHYSICIANS' FEES 200 YEARS AGO.—On Tuesday, Feb. 22, 1631, my father fell sick of a fever, joined with pleurisy, of which disease he lingered three weeks before he deceased. After his first and second letting blood, he found some ease; but the pain returning again to his left side, and the pleurisy appearing still to increase by his frequent spitting of blood, he was the third time persuaded by Dr. Giffard and Dr. Basherville (who ever visited him twice each day he lay sick, and received each of them a twenty-shilling piece every time he came), his two physicians, to open a vein again on the 26th in the morning; after which, as before, he found a little ease for the present only; the same pain returning upon him so violently the Monday night ensuing, as he was enforced to let blood the fourth time. I never saw worse nor more corrupted blood come from any man, so as, had not that which remained been tainted likewise, we might have hoped the loss of so much corrupted blood would have made a way to his speedy recovery. But now his case grew desperate, in respect that his doctors durst not venture on this remedy any more, although he had found ease by it, supposing he had lost too much blood already for one of his age.—*Sir S. D'Ewes' Journal.*

BOOKS RECEIVED.

- Official Correspondence on the Italian Question. London: 1859. (The whole of this important historical document is published in a convenient form for one shilling.)

Mean dew-point temperature	59.0
General direction of wind	S.W.
Whole amount of rain in the week	0.20
Amount of horizontal movement of air in the week	180 miles.

TO CORRESPONDENTS.

J.D.'s letter on the grain weight shall appear next week.

A Subscriber.—A careful report shall be given of all the scientific evidence in the Smethurst trial.

Dr. Jeans.—The Edinburgh College of Physicians have not advertised the list of their recently-acquired Licentiates.

Mr. W.—Our correspondent is quite mistaken. Dr. Mayo, President of the College of Physicians, is a Doctor of Medicine of Oxford, as may be seen by the published Catalogue of Fellows, etc. of the College.

Nemo.—The *Medical Register* is not likely to interfere with the *Directory*. The latter contains a great deal of information which does not appear in the former; and there are thousands of qualified men who have not yet registered. If anyone is on the Register who has no legal qualification, the Council can erase the name.

Specialties in Medicine are no novel inventions. According to Montaigne, they were greatly in favour in ancient Egypt. "The Egyptians," said he, "were quite right in rejecting the universal character of a physician, and in cutting up the Profession into pieces. Let every disease and every part of the body have its own doctor; for that part will assuredly be best treated which is treated specially. Our doctors forget, that He, who provides for everything, provides for nothing; that the entire management of this little world is scarcely digestible by one; and that while they are fearing to stop the course of dysentery, lest they excite a fever, they are killing a friend of mine, who is worth more than the whole lot of them together."

UNIFORM OF NAVAL MEDICAL OFFICERS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your Journal of the 2nd instant, you replied to a correspondent as follows:—"The uniform of Naval Medical Officers has been much improved since the late warrant. There is now no cause for complaint on this head."

For my own part I attach very little importance to the question of uniform, but I think it right to state that the late Board of Admiralty had arranged to give Naval Medical Officers a uniform denoting their increased rank. But the present Board refuse to carry out that arrangement, and the uniform remains precisely what it was before the late warrant.

I am, &c.

A NAVAL SURGEON.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg to forward you the enclosed note, received from Dr. D. Rutherford Haldane, Secretary to the Edinburgh College of Physicians, in answer to an application of mine as to whether the College gave any countenance to the assumption by its ungraduated licentiates of the title of "Doctor."

It rests with your judgment whether the publication of this official statement is likely to be useful.

I am, &c.

SUUM CUIQUE.

"Royal College of Physicians, Edinburgh, July 9, 1859.

"Sir,—I am favoured with yours of the 8th inst. This College does not profess to confer the title of 'Doctor,' neither does it authorise its licentiates to assume it. If licentiates of this or any other College of Physicians call themselves 'Doctors,' they do so upon their own responsibility.

"I am, Sir, your obedient servant,

"D. R. HALDANE, Sec."

(Is it true, or not, that the Edinburgh College addresses its new ungraduated Licentiates as "Doctor?"—S. C.)

WHO IS A DOCTOR?

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you allow me through your Journal to say that I think it behoves the profession as a body to express an opinion on the important point now being debated, whether a Licentiate of a College is or is not to be called a Doctor of Medicine? For my own part, I cannot see what possible claim he can have to such a title; nor do I understand how he can conscientiously make use of it. I would venture to suggest to those of my Professional brethren who view this matter in the same light as I do, that they should resolve to act as I intend to act in it, viz., never to give to any Professional brother the title of Doctor who does not possess the degree

of Doctor of Medicine. If this plan is pretty generally carried out, I will venture to prophesy that the public and all other persons concerned, will soon begin to estimate at their true value the title of "Doctor" as now at present assumed by Licentiates of Colleges. I am, &c. Sic.

ASCARIDES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Let the afflicted obtain from Apothecaries' Hall, an ounce of sulphur precipitatum verum (true precipitated sulphur). Of this as much as can be taken up on a shilling, or ten grains for an adult female, fifteen grains for a male, less for children. Mix this gradually in a wine glassful of milk, to be taken an hour before breakfast: increase daily the quantity, till it produces a tolerable active aperient effect, and the worms will be expelled; reduce the quantity taken gradually afterwards.

I have during forty years prescribed this most useful preparation, under modifications experience has taught me, in cases of eruptions around the ears, even when they have extended beyond the auditory organs, with most complete success.

This preparation of sulphur is very little known to the Professional world, and will be sought for in vain at most Druggists, or even in the Pharmacopœia. It is made at the Hall. I am, &c.

4, Duke-street, St. James's-square, July 11, 1859. W. WRIGHT.

NEW EDINBURGH LICENTIATES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you please inform me where I can obtain a sight of the names of the gentlemen who have had conferred upon them the title of Licentiates of the above College, under the new law, which takes effect during this year of grace? I have been surprised not to see a list of the several hundred Englishmen who, it is understood, have been thus honoured, advertised in your Journal; and still more so, not to find the list in the *Edinburgh Monthly Journal*, which is now said to be wholly in the hands of the ruling body of the Edinburgh College. A course so unusual as this—I mean the course of not publishing the names of men who have become Licentiates of a College of Physicians—demands some explanation. A malicious person would say that there was some method in this silence; and certainly the Edinburgh College lays itself open to unpleasant remarks by what cannot be considered otherwise than a species of concealment.

On ordinary occasions, when men are thus honourably licensed, we see their names in the *Times* next day, and in the *Medical Times* next week, after their admission; why, then, not the names of these gentlemen?

Pray tell an unsophisticated individual why their names are not forthcoming. I am, &c. JOHN QUERY.

CHLOROFORM INHALERS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—With reference to a new Chloroform Inhaler, figured in this week's *Medical Times and Gazette*, perhaps you will allow me to say that I have been using an inhaler, almost exactly similar in construction, during the last twelve months, made by Mr. Ferguson. I am no believer, however, in the infallibility of inhalers, nor do I think it of much moment what inhaler one adopts, if we gauge the effects of the anæsthetic on each particular patient properly: judging in each case of the activity of the right side of the heart by the breathing and circulation in the lungs, and judging of the left side of the heart by a finger always on the wrist. Patients will be observed to take chloroform more quietly when an inhaler is used—but it seems the opinion of the best men that it would be a great misfortune, indeed, if the idea became fixed in the public mind, that tubes, pistons, and inhalers were more necessary than a simple fold of lint or hollow sponge, as used in about half the London Hospitals.

A very fair objection has been raised recently to the mouth-pieces of inhalers, that as one would not wish to use the tooth-brush of a hundred people, of whose gingival antecedents nothing could be known, so also of the mouth-pieces of inhalers, which must be less clean than a piece of lint. I am, &c. CHARLES KIDD, M.D.

Sackville-street, Piccadilly, July 11.

DAY WARDS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Last week's number contained an allusion to some recent additions at St. George's Hospital, especially in providing day-wards, without beds, for convalescents. It should be, however, further stated, that the "Building News," from whose pages one quotation was then made, has rather fallen into a mistake, when the public are told "It is to the credit of St. George's to be the first Hospital in London, that has set the example of such an arrangement;" seeing at Bethlem Hospital, according to Dr. Webster's Notes on Foreign Asylums published in Vol. V., p. 356, of Dr. Winslow's Psychological Journal for 1852, two large apartments or spacious verandahs, made chiefly of glass and iron, where patients of both sexes can separately enjoy bodily exercise in the open air; and, wholly irrespective of weather, have been now some years constructed, at that physician's suggestion, by the eminent architect, Mr. Sydney Smirke. Each appendage measures forty-one feet by twenty-four, to thirteen high; rain cannot enter, and free ventilation is obtained through numerous louvres, which can be shut or opened if required, while the glare of sunshine may be modified, when necessary. The facts here recorded conclusively show to which metropolitan establishment precedence of introduction is most justly due, in reference to the beneficial sanitary improvement just mentioned. I am, &c. F.R.C.P.

June 11, 1859.

[We referred to Hospitals, not to Lunatic Asylums.—Ed.]

THE BATTLE OF THE PLUGS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Not having before me the transactions of the British Association for the Advancement of Science—the eighth meeting, held at Newcastle-upon-Tyne, August, 1838, in which honourable mention is made of my invention; I beg to give an extract from the *Athenæum* of the same year.—Page 613. Section E. *Medical Science*.—"The first paper was read by Mr. Torbeck, on Uterine Hemorrhage, the object of which was to introduce a new mode of applying pressure in certain forms of the disease. A few cases were adduced in proof of its efficiency. A conversation ensued, in which the danger of relying on any merely mechanical treatment, to the exclusion of fundamental principles previously established, was pointed out by Drs. Granville, Lynch, and Knott."

I need not add more; multifarious have been the cases in which this valuable appendage to obstetric practice has proved its efficiency since that period, now, upwards of twenty years. Mr. John Brown, Surgical Instrument Maker of Newcastle-upon-Tyne, manufactured the apparatus and I designated it "Torbeck's Elastic Plug, for arresting Uterine Hemorrhage, etc." he also at the same time made me the first "Elastic Pessary," so that your correspondents will at once perceive that the invention also of the "Elastic Pessary" does not belong to Dr. Gariel, for in his "Applications Médico-Chirurgicales du Caoutchouc Vulcanisé," you will at once perceive his invention of its very recent date. Vulcanised India-rubber was not known twenty years ago. I am indeed delighted to find that the "Elastic Plug" has proved so valuable in the hands of Dr. Murray, in the case of Placenta Prævia, but do not certainly admire the introduction of the plug into the os uteri, my experience, now over thirty-six years, proving the contrary. I am, &c.

Darlington, July 8, 1859.

Thos. R. TORBECK, M.D.

AIR-DILATORS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Your readers will doubtless see from the tone of Mr. Murray's observations, that it is quite unnecessary for me to do more than simply refer to the following extract, from which it will be evident that I have no reason to "shirk the question at issue," seeing that Mr. Murray's (?) case did not occur until the 16th April, i.e. more than month after the meeting referred to, previous to which, when lecturing for Professor Simpson during his indisposition, I had occasion more publicly to suggest the various obstetric uses to which I believed the air-dilator could be applied. I am, &c.

21, Queen-street, Edinburgh, July 12, 1859.

ALEXANDER KEILLER.

Dr. Keiller forwards the following abstract of the proceedings of the meeting of the Edinburgh Obstetrical Society, held on the 9th of March:—

"Dr. Keiller communicated to the Society some observations on a new mode of dilating the os uteri and passages, which he had successfully adopted in several cases. The appliance consisted of an ordinary vulcanised India-rubber bag, or dilatable pessary, which could be readily introduced in an uninflated state into the vagina, or into the os uteri, and afterwards inflated to the required extent by means of an attached syringe, or other suitable apparatus for pumping in air. The smooth and highly distensible material of which air-pessaries are usually made; the comparative ease with which they can be introduced; their ready and equable dilatability; their slowly, or, if need be, instantaneously, collapsing or allowing the injected air to escape,—were advantages which none of the appliances or modes hitherto adopted for vaginal or uterine dilatation seemed to possess. The comparatively slow and irritating action of sponge, or other substances ordinarily used as tents or uterine dilators, together with the readiness with which they are found to absorb offensive discharges, are objections which cannot be said to apply to the vulcanised caoutchouc inflating bag, or air-pessary, which can be so readily and successfully used, either as a dilator or tampon, in all cases in which dilatation, compression, or plugging are usually had recourse to in obstetric practice. Dr. Keiller exhibited various forms of the dilatable pessary he had used, some of which he had specially got made for dilating the os uteri in cases in which it was considered necessary to do so. Dr. Keiller cited the particulars of several cases in proof of the practical value of this novel use of the air-pessary. Dr. Weir and Dr. Pattison had witnessed its use in some of the cases referred to by Dr. Keiller, and testified to the efficiency and apparent value of the appliance."

COMMUNICATIONS have been received from:—

PROFESSOR SIMPSON; DR. CONOLLY; DR. ROLLESTON, Oxford; DR. ALEXANDER WOOD, Edinburgh; DR. BALLARD; DR. KEILLER, Edinburgh; MR. GRIFFIN; DR. ARNOTT; MR. J. J. MURRAY; DR. ROOKE; MR. LAURENCE; MR. PROPERT; MR. FINNEY; MR. STOKES; A VOICE FROM SHEFFIELD; MR. STATTER; DR. JONES; MR. DONOVAN; DR. KIDD; DR. TORBECK; A NAVAL SURGEON; DR. JEANS; NEMO, ETC.

APPOINTMENTS FOR THE WEEK.

July 16. *Saturday (this day).*

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m. King's, 2 p.m.; Charing-Cross, 1 p.m.

ROYAL BOTANIC SOCIETY, 3½ p.m.

18. *Monday.*

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.

19. *Tuesday.*

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

20. *Wednesday.*

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopaedic Hospital, 2 p.m.; Middlesex, 12½ p.m.

NORTH LONDON MEDICAL SOCIETY, 8 p.m.

21. *Thursday.*

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2½ p.m.

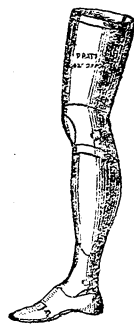

22. *Friday.*

Operations, Westminster Ophthalmic, 1½ p.m.

EXPECTED OPERATIONS.

King's College Hospital.—The following operations will be performed this day (Saturday):—

Mr. Ferguson—For Ununited Fracture; Lithotripsy. Mr. Bowman—For Removal of Breast.

Pratt's Artificial Leg.

J. PRATT begs to call the attention of the Profession to the following Testimonial, just received:—

"Somerset,

June 20th, 1858.

"DEAR SIR,—It affords me much pleasure in being able to state that the Artificial Leg which you supplied me with is far beyond my best anticipations. From its being so LIGHT IN WEIGHT, and its action in the foot so natural, I can walk, or ride on horseback, with ease and comfort; and few indeed would detect it as being other than natural. It has given me full satisfaction.

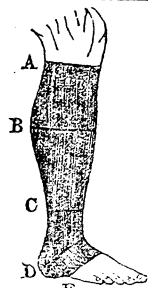

I am, dear Sir, yours very truly,
J. W.

To Mr. J. Pratt,
Surgical Instrument Maker,
420, Oxford-street."

South African Sherry, 19s. 6d. Port,

22s. Claret, 18s. Madeira, 24s. Amontillado, 26s. Cognac, 18s. 6d. Her Majesty's Wine Merchant. Specially appointed since May, 1840. JAMES MARKWELL, Cellars, 35 to 40 & 45, Albemarle-street—Offices, 40, Albemarle and 4, Stafford Streets. Ports, from 30s.; Sherries, 30s.; Madeira, 42s.; Hocks, 40s.; Moselles, 4s.; Sparkling Hocks and Moselles, 48s.; Ditto, St. Peray, 54s.; Ditto, Burgundy, 60s.; Clarets, 28s.; Chablis, 38s.; Cote Rotie, 48s.; Champagne, 44s.; Sauterne, 40s.; Ditto, Yquem, 80s.; Essence of Turtle Punch, 56s.; Old Tom, 11s. 6d. All kinds of Foreign Spirits and Liqueurs. Particular and direct Shipments of Montilla, Vino di Pasto, Amontillado, Oloroso, Xres Viejo, Manzanilla, Longworth's Sparkling and Dry Catawba American Peach Brandy; Monongahela and Bourbon Whisky; and Sole Agent for the Celebrated Yankee Bitters. Bottled Stock for inspection, 6000 dozen. Cash or Reference. As usual, very liberal prices given for genuine Old Bottled Wines. Half-pints of first-class Champagne only.

N.B.—A considerable quantity of the Old Bottled Wines removed to Mr. M.'s Stock from Long's Hotel, North and South American Coffee House, Shugborough Park, and the celebrated Reading Sale.

Voullion's Patent Elastic SPIRAL SUPPORTS, "WITHOUT SEAMS OR LACING."

200 Leading Members of the Medical Profession recommend them in preference to all others.

DIRECTIONS FOR MEASUREMENT:—

For STOCKINGS—Circumference round the instep, ankle, calf, and above calf.

For KNEE-CAPS—Circumference below knee, at knee, and above knee.

For THIGH-PIECE—Circumference round top and bottom of thigh.

For ABDOMINAL SUPPORTS—Circumference of body above and below the hips.

Illustrated and Priced Catalogues free. Prices reduced 30 per cent.

MEACHER, Operative Chemist, sole Manufacturer, 105, Crawford-street, Portman-square.

Scammony Manufactured from the

ROOT.—This Pure Resin may be had of all Wholesale Druggists at 28s. per lb.

The Medicinal value of this Scammony was fully explained at a meeting of the Pharmaceutical Society, and reported at length in their journal of March last, from which the following are extracts:—

"From these numerous observations, one hundred and twenty in number, together with many others which have not been tabulated, I am quite convinced that the scammony prepared by the new process from the untapped root is quite equal, as a remedy, to the very best virgin scammony which is met with in commerce, and equal, in fact, to the resin which is extracted from commercial scammony by means of ether; and it possesses this most important advantage over the scammony of commerce, namely, of being entirely free from the frauds which are almost constantly practised upon it in the country where the plant grows, and in which it has hitherto been collected, and, therefore, being perfectly uniform in its physical characters, composition and therapeutic action. There can, therefore, be no objection, but, on the other hand, manifest advantage, in employing it in place of the scammony commonly met with.

"A. B. GARROD, M.D., F.R.S., F.R.C.P.

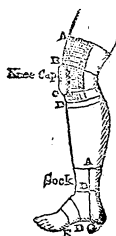

"Professor of Materia Medica, Therapeutics and Clinical Medicine at University College; Physician to University College Hospital."

"I have endeavoured to ascertain the relative activity of Messrs. M'Andrew's scammony, and of a fine specimen of commercial virgin scammony, by prescribing these drugs alternately in equal doses to the same patient. The results, according to the judgment of myself and others who have assisted me in watching the cases, is that in most instances Messrs. M'Andrew's scammony has proved itself decidedly more active than the virgin scammony. As to pleasantness of operation, or the reverse, there seemed to be no choice between the two specimens.

"That a preparation of scammony should be a little more or a little less active is of comparatively small importance. It is far more important that the drug should have a fixed and uniform composition and activity, so that the prescriber may know, with an approach to certainty, what doses are required to produce a given effect. This advantage of uniform activity Messrs. M'Andrew's scammony seems likely to possess over the scammony which has hitherto been in common use, and which is a drug notoriously of most uncertain composition and power.

GEORGE JOHNSON, M.D., F.R.C.P.

Professor of Materia Medica and Therapeutics in King's College; Physician to King's College Hospital.

J. & E. BRADSHAW, late Shoolbred and Bradshaw,

34, JERMYN-STREET,

begs to call attention to the various improvements in Patent ELASTIC STOCKINGS, BELTS, KNEE-CAPS, SOCKS, and Ladies' and Gentlemen's SPINE SUPPORTERS. A new description of BELT, invaluable for prevention of Cholera and the cure of Rheumatism. Lumbago, &c.

N.B. Every description of INDIA-RUBBER BANDAGE, vulcanised on the newest principle.

Directions for measurement sent by post. N.B. A Liberal Discount to the Profession.

A female to attend on ladies.

H. Silverlock's Medical Label Ware-

HOUSE, Letter-Press, Copper-plate, and Lithographic Printing Offices, Wardrobe-terrace, Doctors'-commons, London, E.C.

H. SILVERLOCK'S stock of Labels for Dispensing purposes having been recently revised and enlarged, now consists of upwards of 800 different kinds. Yellow and Green Labels for Drug Bottles, Drawers, &c., at per book or dozen: a Book, containing a selection in general use in Surgeries or Dispensaries, 10s. 6d. Priced Catalogues of the above may be had, post free, on application. Printing of every Description at Moderate Prices.

Or SACCHARATED CAPSULES, approved of by the French College of Physicians, successfully administered in the Paris and London Hospitals, and acknowledged by them to be the best remedy for the cure of certain diseases. (See the "Lancet" of 6th November, 1852; "Medical Times" 10th December, 1852; a copy of which will be forwarded on application.) Price per 100, 4s. 6d.; 50, 2s. 9d.

To be had of the Inventor, GABRIEL JOZEAU, sole French Chemist, 49, Haymarket, London, whose name is printed on the Government stamp, and of all the principal Chemists of England.

SUMMER DIET.

BROWN & POLSON'S PATENT CORN FLOUR.

This is superior to anything of the kind

known—LANCET. Obtain it from Family Grocers, or Chemists, who do not substitute inferior articles. It is preferred to the best Arrow Root; for Breakfast boiled simply with milk; Dinner or Supper, in Puddings, warm or cold, Blancmange, Cake, &c., and especially suited to the delicacy of Children and Invalids. Packets, 16 oz. 8d.

Blancard's Pills of Unchangeable IODIDE OF IRON,

Recommended by the Academy of Medicine of Paris, and authorised by the Medical Council of St. Petersburg, Extensively tried in the Hospitals of France, Belgium, Ireland, Turkey, &c. Favourably noticed at the Universal Exhibition of New York, 1853, and Paris, 1855.

"Of all the modes hitherto proposed of administering iodide of iron in the pure state, I think Mr. Blancard's the best."—Chemistry applied to Therapeutics, by M. Mialhe, Deputy-Professor to the Faculty of Medicine of Paris, Pharmacien to the Emperor, 1856, p. 319.

These Pills stand now very high in the therapeutics of every country, as may be seen by the above quotations, and also by the numerous scientific articles in medical periodicals and works (a).

Being enveloped in a very thin resino-balsamic coating, they present the great advantage of not being liable to any deterioration, of having no taste, of being small, and not distressing the stomach. As they possess the properties both of iodine and iron, they are especially beneficial in chlorotic, scrofulous, tubercular, or cancerous affections, as also in leucorrhœa, amenorrhœa, anemia, &c. &c., and they furnish the medical man with an excellent means of modifying lymphatic, feeble, and debilitated constitutions. Dose, 2 to 4 pills a day.

N.B.—Impure or altered Iodide of Iron is an unsafe remedy, and may even prove dangerous. Only such bottles as bear an electro-plated seal fixed to the lower part of the cork, and the signature of the inventor placed on a green label, are to be considered as prepared by Mr. Blancard. The public should beware of spurious imitations.

To be had at M. BLANCARD'S, Pharmacien, Rue Bonaparte, No. 40, Paris. General dépôt in England at M. Gabriel JozEAU's, French chemist, 49, Haymarket, London. In Ireland, at Mr. Vitties, Stevens's Hospital, Dublin. In the United States, at D. and S. Fougere, Chemists, 30, North William-street, New York. To be obtained retail from the principal Chemists.

(a) Bulletin de l'Académie de Med 1850, page 1015; Gazette Médicale, Aug. 17, 1850; Union Médicale, Aug. 15 and 22, 1850; Gazette des Hôpitaux, March 15, 1853, and June 10, 1854; Gazette Hebdomadaire de Médecine et de Chirurgie, Aug. 31, 1855; Revue de Thérapeutique Médico-Chirurgicale, Feb. 15, 1855; Abeille Médicale, Revue Clinique; Répertoire de Chimie et de Pharmacie; Annuaire de Thérapeutique pour 1851, page 199; Orfila, Elements of Chemistry; Mialhe, Chemistry applied to Therapeutics, 1856, p. 319; Quevenne, Essay on the Physiological and Therapeutic Action of Preparations of Steel, page 97, 1854; Bricheteau, Traité on Chronic Diseases seated in the Respiratory Organs; Soubeiran, Traité on Pharmacy; Dorvault, Officine, &c. &c.

ADDITIONAL TESTIMONY ON THE EXTRAORDINARY EFFICACY OF
DR. J. COLLIS BROWNE'S
 (M.R.C.S.L., EX-ARMY MEDICAL STAFF)

C H L O R O D Y N E.

(Entered at Stationers' Hall.)

MEDICAL PROPERTIES—Anodyne, Diaphoretic, Sedative, Astringent, Antispasmodic, Diuretic.

From W. R. DAWES, Esq., F.R.C.S.
 Haddenham.

DEAR SIR,—You should have heard from me sooner respecting the effects of Dr. J. Collis Browne's Chlorodyne, but the fact is, that I have found it so universally applicable as a sedative, that there is great difficulty in making a selection of cases which most strikingly mark its beneficial action without rendering my report inconveniently prolix. I can, however, most truly say, that it is a remedy more generally efficient than any other with which I am acquainted. Its sedative and anodyne effects are not only more speedily produced, but they are also more lasting, and are not followed by exhaustion, or headache, or disturbance of the digestive functions; on the contrary, in many instances its continued use has been followed by exhilaration of spirits and improvement of appetite, especially in the various painful symptoms attending uterine irritation. In hysteria and in dysmenorrhœa, this remedy acts like a charm, as also in nervous headaches and in many cases of cough. In fevers, combined in the early stage with tartarised antimony, it is often of signal service; nor is an increase of dose usually requisite to maintain its beneficial action. In a case of phthisis, the moderate dose of ten minims, taken every night, has sufficed for many months to secure quiet rest, scarcely disturbed by cough, while the omission of it is invariably followed by a restless and coughing night. One fact strikes me as very remarkable—namely, that while the tendency of Chlorodyne to produce constipation is so slight as rarely to require an aperient, it has never failed speedily to stop diarrhœa, or to extinguish attacks of ordinary Cholera. In only two or three instances has it disagreed. The sleep which follows the composing influence of the medicine is peculiarly light and refreshing.

Caution.—Owing to the frequent complaints made by Physicians and General Practitioners of the distress and disappointment caused by the substitution of fraudulent imitations of Dr. J. Collis Browne's Chlorodyne, when prescribed by them for patients, as also tended to them as the genuine (proofs of which are in possession), it is found necessary to adopt the Government Stamp, having the name of Dr. J. Collis Browne's Chlorodyne engraved thereon.

Medical men, Hospitals, and Dispensaries, desirous of obtaining it without stamp, must forward their orders direct, duly authenticated, to the manufactory, when they can be supplied in bulk, a liberal discount being allowed.

Price 3s. per ounce, and in quantity of 10 ounces carriage free.

Sole Agent and Manufacturer—**J. T. DAVENPORT**, Operative and Pharmaceutical Chemist,
 33, GREAT RUSSELL-STREET, BLOOMSBURY-SQUARE, LONDON.

DR. DE JONGH'S

(Knight of the Order of Leopold of Belgium)

LIGHT-BROWN COD-LIVER OIL.

CAUTION.

Serious and repeated complaints having been made of a discreditable system pursued by many Chemists and Druggists of intrusively recommending or surreptitiously substituting a pale, yellow, or coarse brown preparation, when Dr. de Jongh's Oil is prescribed, the Medical Profession are respectfully and earnestly solicited to afford their assistance in counteracting and repressing a practice alike injurious to their patients and to the fair repute of a remedy now held in such high and general estimation. In all cases where this Oil cannot be procured from a respectable Chemist, application should be made to Dr. de Jongh's Agents,

ANSAR, HARFORD, & CO., 77, Strand, London, W.C.

By whom any quantity will be immediately forwarded.

WALTERS' INDIA-RUBBER URINALS.

F. WALTERS having originally invented these Urinals, begs to warn the Profession of the many bad and useless imitations which are now sold, and he would advise them, before purchasing, to look that they are stamped with his name; as, unless that be the case, he cannot guarantee them.

These conveniences are made for those who require them only occasionally, during a long journey, as well as for those invalids who use them always. Mr. WALTERS has much improved them by making them of *Etherised India-Rubber*, which adds very greatly to the strength of the India-Rubber, at the same time that it prevents its sticking together; by this means he is enabled to make them less stiff and harsh than hitherto, and yet to retain all the advantages of that stiffness. There is a patent valve, which prevents the return of the fluid; and they may be worn either sitting, walking, or lying, without the slightest inconvenience, and without being perceived by any one.

WALTERS' CONVENIENCES FOR LADIES will be found particularly useful during pregnancy. They are perfectly soft and flexible, and may be worn with perfect comfort.

All Orders must be accompanied by a Post-office order or reference.—Entrance for Ladies at the private door, where a Female attends.

MANUFACTURER OF ELASTIC STOCKINGS, BELTS, &c.

16, MOORGATE STREET, NEAR THE BANK, LONDON. E.C.

MEDICAL AGENCY.

NOTICE OF REMOVAL AND CHANGE OF FIRM.

Mr. Lara (for the last eight years the sole representative of LANE and LARA, Medical Agents and Arbitrators and Lunatic Asylum Registrars,) begs to inform the Profession that, in consequence of the daily increasing support with which he has been favoured, and for which he tenders his sincerest thanks and acknowledgments, he has taken into PARTNERSHIP Mr. James Maxfield Walters, a gentleman who has had considerable experience in the business. It will, therefore, from and after Christmas, 1858, be carried on, under the Firm of LARA and WALTERS, at 6, PUMP-COURT, Middle Temple, E.C., whither they have removed their Offices from 22, Bucking-ham-street, Adelphi, in order to provide that larger accommodation which a constant intercourse with a great majority of the entire body of General Practitioners in England has rendered necessary.

Partnerships and Practices sold and valued: Asylums transferred: Arbitrations effected: Assistants provided (if for a permanence without charge to Employers): and every other description of business transacted for the Profession at a fixed and moderate cost. Attendance from 11 till 4.

Mental Disorders.—Wye House,
BUXTON, DERBYSHIRE—PRIVATE ESTABLISHMENT for the Care and Treatment of a select and limited number of persons mentally affected.

Resident Proprietor—T. DICKSON, L.R.S.C.E.,
Late Medical Superintendent of the Manchester Lunatic Hospital.
Wye House is delightfully situated in its own grounds of twelve acres at Buxton, and forms part of the magnificent scenery of Wye Dale. The well-known salubrity of Buxton, and the hygienic effects of its waters and baths, renders it a desirable locality for Invalids Nervously or Mentally affected. Ample means are provided for the occupation and amusement of the Patients, including carriage and garden exercise.

North Staffordshire Infirmary, Etruria,
STOKE-UPON-TRENT.—HOUSE PUPIL WANTED.—WANTED IMMEDIATELY, for a term of three years, A HOUSE PUPIL and DRESSER. He will be required to reside in the House, and will have excellent opportunities of acquiring Medical and Surgical knowledge. For terms, &c., apply to
RALPH HORDLEY, Secretary.

Wanted, at the Bristol Royal Infirmary,
a DISPENSER (who will neither reside nor board in the House), to take the entire management of the Dispensary of this Institution. He must understand purchasing drugs, and compounding as well as dispensing medicines. Salary, from £100 to £120 per annum. The highest testimonials as to character and ability will be required. Further particulars may be obtained on application to the Secretary, at the Institution.
Applications to be sent to the Committee on or before Monday, the 1st August next.
By order of the Committee,
WILLIAM TRENNERY, Secretary.

Bristol Royal Infirmary, July 5, 1859.

Royal Berkshire Hospital, Reading.—
The Situation of HOUSE-SURGEON to the above Institution is now vacant. The number of beds at present available is nearly a hundred, and the salary attached to the office will commence at £60 per annum, with board and lodging. It is necessary that any Gentleman holding it should be unmarried, a Member of one of the Royal Colleges of Surgeons of Great Britain and Ireland, and also of the Apothecaries' Company.
Testimonials as to character and efficiency to be forwarded on or before the 1st day of August, addressed to the Secretary, from whom, in the meantime, any further particulars may be learned.
The Election will be held on Tuesday, the 9th day of August, when those Candidates whose presence is required will receive notice to attend.
N.B.—A personal canvass of the Members of the Board of Management is prohibited.
Reading, July 13, 1859.

Addenbrooke's Hospital, in the Town
of CAMBRIDGE.—HOUSE APOTHECARY.—NOTICE IS HEREBY GIVEN, that a SPECIAL GENERAL COURT of the PRESIDENT and GOVERNORS of the above Institution, will be held in the Board-Room of the said Hospital, at Eleven o'clock in the forenoon of the 5th SEPTEMBER next, for the ELECTION of a GENTLEMAN, to fill the office of House Apothecary, vacant by the resignation of Mr. Edmund Carver. The Gentleman elected will have to reside, and will be boarded in the Institution. The Salary is £86 a-year.
All Candidates must be duly qualified, and must forward Testimonials as to ability and character, sealed up, under cover, to the Secretary, before the 31st of August, and must produce their qualifications to the Court, on the day of Election.

And notice is hereby further given, that in case of a contest, votes will be received by the Court, at the Board-Room, from 12 o'clock at noon, until 5.30 o'clock in the afternoon of the said fifth day of September, when the Election will finally close.

Ladies only can vote by proxy, forms of which, and all particulars, may be had upon application, at the office of the Secretary.

By Rule 24 no Governor can be allowed to vote whose Subscription is unpaid; nor unless he has been a Governor for six months, except he be a benefactor of Twenty Guineas and upwards.

Annual Subscriptions became due on the 20th of September last, and as Subscriptions are paid in advance for the current year, all Governors by yearly subscription of two guineas must pay their Subscriptions up to the 29th September, 1859, together with all arrears, if any, to EDMUND JOHN MORTLOCK, Esquire, Banker, Cambridge, the Treasurer, before their votes can be received.
By order,
FREDERIC BARLOW, Secretary.

St. Andrew's-street, June 30th, 1859.

Medical Transfer and Partnership.

30, Bucklersbury, Cheapside.

Mr. Orridge, Medical Transfer Agent,
Referee, and Valuer of Medical Property, may be consulted, at the above Address, by Gentlemen about to receive PARTNERS, or to RELINQUISH or to COMMENCE Practice.
Mr. Orridge is known to many of the Hospital Physicians and Surgeons of London.

He has been concerned professionally for a considerable proportion of the most influential Practitioners (including Partners in many of the leading Medical Firms), to whom he has the satisfaction of being permitted to refer—a privilege that he trusts will be regarded as a proof of the sincerity of his endeavours to conduct these transactions in an honourable and straightforward manner.

Gentlemen desirous of obtaining Mr. Orridge's opinion, or requiring his attendance professionally in any part of England, can obtain terms on application, by (confidentially) transmitting name and address.

Office Hours, from Eleven to Four.

Stourbridge Dispensary.—Wanted, a

HOUSE-SURGEON and SECRETARY. Salary, £120 per annum, with house and coals. Candidates must be Members of the Royal College of Surgeons and Licentiates of the Apothecaries' Company, London. The Gentleman elected will be required to enter into an agreement not to practise within three miles of the town until three years have elapsed after resigning the appointment. Applications and testimonials to be forwarded to Mr. Way, the present House-Surgeon, on or before the 20th day of August. The Election will take place the following Tuesday. Duties commence September 30th.—Stourbridge, July 11, 1859.

Eastern Dispensary of Bath.—A

RESIDENT MEDICAL OFFICER is required, who must possess the Diplomas of a Royal College of Surgeons and Society of Apothecaries. The salary is £80 per annum (rising to £100 per annum with length of service), together with furnished apartments, coals, gas, and domestic attendance. The election lies with the Governors and Subscribers entitled to vote. A preference (*ceteris paribus*) will be given to such Candidates as will undertake to continue in the office for a period of at least two years. Testimonials (post paid, and marked "Eastern Dispensary") to be forwarded, on or before the 31st inst., to E. Turner Payne, Esq., Honorary Secretary, 5, Old King-street, Queen-square, Bath, who will afford any further information required.

N.B.—Notice of the Day of Election will be sent to each approved Candidate.
Bath, July 12, 1859.

Mr. James Robinson, Dentist, has
REMOVED from No. 7 to No. 5, GOWER-STREET, Bedford-square, London, where he may be CONSULTED daily from 10 to 4.
5, Gower-street, Bedford-square.

To Medical Men and Others.—

WANTED, BOARD and RESIDENCE for a Gentleman of respectability and intelligence, who is in the habit of occasionally drinking to excess. He is otherwise an agreeable companion. Address, stating terms, to A. B., No. 29, Portland-street, Southampton.

For Immediate Disposal, One-half of a

GENERAL PRACTICE, which has averaged for several years past, £1000 to £1200 per annum. £300 per annum secured by contracts Locality, a provincial town, within a few minutes' walk of sea and railway. Valid reasons for withdrawal assignable by the retiring partner. Address to Messrs. Gale, Baker, and Oldfield, Bouverie-street, Fleet-street, London.

To be Let, in the Old Stein, Brighton,

a First-class HOUSE, fitted either for a Private Family or Professional Residence. Rent, £210 per annum. For further particulars, apply to Mr. Wilkinson, House Agent, North-street, Brighton; or to Laher and Wood, New Bond-street, London.

Partnership.—A M.D. Edin. (1851),

and L.R.C.S.E. (1851), desires a PARTNERSHIP or SHARE of a PRACTICE in ENGLAND. The Advertiser has had considerable Hospital experience, besides having served in the H. E. I. C. Service for some years, and now is desirous of obtaining a Practice at home. Age 30. Apply to M., Messrs. Cay and Black's, 65, George-street, Edinburgh.

Medical Pupil.—October Session.—

A Gentleman in Practice near one of the Metropolitan Hospitals has accommodation for a HOUSE PUPIL. Every attention will be paid to his home comforts and professional acquirements. Unexceptional references will be required. Address, by letter, B. R., care of Mr. Baker, Instrument-maker, High Holborn, W.C.

To Invalids.—A married Medical Man,

without family, residing in the country, wishes to receive into his house an INVALID LADY. For particulars, address A. B., 21, Harp-lane, London, E.C.

London: Printed by CHARLES REED and BENJAMIN PARDON of 1, 2, and 3, Lovell's-court, Paternoster-row, in the City of London, and published by JOHN CHURCHILL, at the Publishing Office, No. 11, New Burlington-street, in the Parish of St. James, in the City of Westminster.—July 16, 1859.

NOTICE.

THE ANNUAL CIRCULAR of the MEDICAL DIRECTORY for 1860

It will be posted to every Member of the Profession during the first week in August. The New Edition will contain every name as it appears in the Official Register, in addition to the names of vast numbers of the Profession who, although unquestionably qualified, have declined to register. The "Directory" will thus embrace the Register entire, with addenda to each name, by which alone the *status* of each Practitioner can be ascertained, added to many hundreds of pages of Professional information, not to be found elsewhere, and which have rendered the "Directory," as a book of reference, almost indispensable to the Medical Practitioner.

OFFICE, 11, NEW BURLINGTON-STREET.

Now ready, price 7s.,

Dedicated by permission to the Right Hon. the Earl of Shaftesbury,

On the State of Lunacy and the Legal

PROVISION for the INSANE; with Observations on the Construction and Organisation of Asylums. By J. T. ARLIDGE, M.B., A.B., L.R.C.P. (Lond.), formerly Medical Superintendent of St. Luke's Hospital. John Churchill, New Burlington-street.

Second Edition, with Additions, Coloured Plates, 7s. 6d. cloth,

The Diseases of the Rectum. By

RICHARD QUAIN, F.R.S., Professor of Clinical Surgery in University College.

London: Walton and Maberly, Upper Gower-street, and Ivy-lane,
 Paternoster-row.

NEW EDITION OF SKEY'S OPERATIVE SURGERY.

In crown 8vo, with many Woodcuts, price 12s. 6d. cloth,

The Principles and Practice of

OPERATIVE SURGERY. By **FREDERIC C. SKEY, F.R.S.**, Member of the Council of the Court of Examiners of the Royal College of Surgeons of England, Surgeon to St. Bartholomew's Hospital, &c. &c. Second Edition, revised and enlarged.

"We accept it as the candid record of the experience of one of the foremost amongst us—as the work of a man who has thought deeply and independently, and has honestly endeavoured to make the knife—what, indeed, it ever should be—the last resource of the Surgeon."—*The Lancet*.

"The independence of thought and research which characterises it gives it a peculiar merit, and justifies our recommending it to every earnest student of his profession."—*British and Foreign Medical Review*.

"There is much sound and wholesome doctrine in Mr. Skey's work—his reputation as a good Surgeon cannot fail to be advanced by it."—*Medical Times and Gazette.*

"We are glad to see this Second Edition, and can honestly recommend it as an invaluable guide to operative practice."—Medical Circular.

London: Longmans, Brown, Green, and Longman.

VOL. XL. No. 1034.—NEW SERIES, No. 473.

GALBRAITH AND HAUGHTON'S NEW SERIES OF SCIENTIFIC
MANUALS.

This day is published, in fep. 8vo, with numerous Woodcut Illustrations,
price 2s. sewed,

Manual of Protozoa; with a General

In Introduction on the Principles of Zoology. By J. REAY GREENE, B.A., M.R.I.A., Professor of Natural History in the Queen's College, Cork, &c. Being the first of a New Series of Manuals of the Experimental and Natural Sciences; edited by the Rev. J. A. GALBRAITH, M.A., and the Rev. S. HAUGHTON, M.A., F.R.S.

London : Longman, Green, Longman, and Roberts.

THE LATE DR. THOMAS BULL ON BLINDNESS.

Just published, in fcp. 8vo, price 4s. 6d. cloth,

The Sense of Vision Denied and Lost.

1 By THOMAS BULL, M.D., Author of "Hints to Mothers," and "Hints on the Management of Children" (for the last Eight Years of his life deprived of Sight). Edited by the Rev. B. G. JOHNS, Chaplain of the Blind School, St. George's-fields. With a brief Introductory Memoir of the Author by Mrs. BULL.

London: Longman, Green, Longman, and Roberts.

Just published, 8vo, 2s. 6d.

Epiphora, or Watery Eye: its Successful

Treatment by the new Method of Dilatation. With Illustrative Cases. By JAS. VOSE SOLOMON, F.R.C.S., Surgeon to the Birmingham Eye Infirmary.

John Churchill, New Burlington-street.

This day, 8vo, 5s.

On the Classification and Geographical

DISTRIBUTION of the MAMMALIA: being the Reade Lecture delivered before the University of Cambridge, 1859. With an Appendix "On the Gorilla," and "On the Extinction and Transmutation of Species." By RICHARD OWEN, F.R.S., Superintendent of the Natural History Department in the British Museum.

London: John W. Parker and Son, West Strand.

On Poverty of the Blood, and its SYMPATHETIC DISORDERS.

London: Whittaker & Co.

The Harrogate Spas. 4th Edition.

By Dr. PIGGOTT (Harrogate).
John Churchill, New Burlington-street.

Fourth Edition, 32mo, cloth, 2s. 6d.

Shaw's Medical Remembrancer; or,

Book of Emergencies; concisely pointing out the immediate Remedies to be adopted in the first moments of danger from Poisoning, Drowning, Apoplexy, Burns, and other Accidents; with the Tests for the Principal Poisons. Corrected, with Additions.

By JONATHAN HUTCHINSON, M.R.C.S.
John Churchill, New Burlington-street.

DR. KIDD ON ANÆSTHETICS.

On Æther and Chloroform.

By CHARLES KIDD, M.D. (New Work).

"Dr. Kidd will creditably fill the shoes of the late Dr. Snow."—Edinburgh Medical Journal.

Henry Renshaw, 356, Strand.

Now ready,

The Medical Register, published

pursuant to an Act passed in the XXI. and XXII. Victoria, Cap. XC., to regulate the Qualifications of Practitioners in Medicine and Surgery. It may be obtained upon application, by letter or otherwise, at the office of the General Council of Medical Education and Registration of the United Kingdom, 32, Soho-square, London, W.
Price 7s. 6d. or post free 8s.

Braithwaite's Retrospect.—New

VOLUME.—Just published, price 6s., the 39th Volume of this Work, giving an epitome of the most important matter published in the Medical Journals and Transactions of Societies within the last six months: added to each Volume is a small Dictionary of Medical Treatment. By W. BRAITHWAITE, Lecturer on Diseases of Women in the Leeds School of Medicine, &c.

Also, reprinted from the above,
DISEASES of the EYE, No. 2, price 1s.
DISEASES of WOMEN, No. 2, price 1s.
EXAMINATION of HOMŒOPATHY, No. 1, price 2d.
London: Simpkin, Marshall, and Co. Edinburgh: Oliver and Boyd.
Dublin: Hodges, Smith, and Co.

Just Published, Price 3s. 6d., with 200 Descriptive Cases, and Illustrations in Chromo-Lithography,

Amputations and Artificial Legs,

HANDS, etc. By W. R. GROSSMITH, of 175, Fleet-street, London. "Mr. Grossmith has offered some good practical suggestions for the consideration of the operator, and has entered more fully into the subject than has hitherto been attempted."—The Lancet, Nov. 14th, 1857.

"Mr. Grossmith's artificial limbs are well constructed, and on the best system."—Paris Exposition Jury Reports.

London: Longman and Co. Dublin: Fannin and Co.; and from the Author, post free.

Now ready, in One Vol. 8vo, pp. 370, price 7s. 6d.

A Treatise on Medical Electricity,

Theoretical and Practical; and its Use in the Treatment of Paralysis, Neuralgia, and other Diseases. By J. ALTHAUS, M.D.
Triibner and Co. 60, Paternoster-row.

Just published, in one volume, royal 8vo, pp. 992, handsomely bound in cloth, price 18s.

A Dictionary of Medical Science. By

ROBLEY DUNGLISON, M.D. LL.D. Fifteenth Edition, revised and very greatly enlarged.

It reviewing the fourteenth edition of this celebrated work, the "British and Foreign Medico-Chirurgical Review," for July 1853, page 205, remarked, that the labour which had been bestowed upon the work "had been something prodigious," adding, "the work, however, has been now done, and we are happy in the thought that no human being will have again to undertake the same gigantic task. Revised and corrected from time to time, Dr. Dunglison's 'Medical Lexicon' will last for centuries."

Yet, in the present edition, not only has the work been revised and corrected, but about six thousand subjects and terms have been added, which are not to be found in the one noticed by the "British and Foreign."

Triibner and Co., 60, Paternoster-row, London.

Pepsine.—M. Boudault begs to state

that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, her Majesty's Chemist, 277, Oxford-street, London, to whom all applications respecting it must be addressed.

Second Edition of Boudault on "Pepsine," with Remarks by English Physicians. Edited by W. S. SQUIRE, Ph.D., published by J. Churchill, London, may be also had of the Author, 277, Oxford-street, price Sixpence.

The Middlesex Hospital, Session

1859-60.—The Session opens on MONDAY, October 3rd, with an Introductory Address by Mr. HENRY, at Eight o'clock p.m.

The Hospital, from recent enlargements, contains upwards of 300 beds, of which 185 are for Surgical and 120 for Medical cases. The Cancer establishment receives 33 patients. Wards are specially appropriated to cases of Uterine Disease and of Syphilis. 2100 in-patients were admitted during the past year; the number of out-patients during the same period amounted to 16,469.

MEDICAL OFFICERS.—Dr. Stewart, Dr. Goodfellow, Dr. H. Thompson, Dr. Frere, Dr. F. Weber, Dr. Charles Coote, Mr. Shaw, Mr. De Morgan, Mr. Moore, Mr. Henry, Mr. Nunn, Mr. Flower.

Post-mortem Examinations are conducted by Dr. Coote.

LECTURERS.—Clinical Medicine: the Physicians to the Hospital.—Theory and Practice of Medicine: Dr. Stewart and Dr. Goodfellow.—Clinical Surgery: the Surgeons to the Hospital.—Surgery: Mr. Shaw.—Physiology: Mr. De Morgan.—Anatomy: Mr. Moore.—Practical Anatomy: Mr. Nunn and Mr. Flower.—Pathological Anatomy: Mr. Sibley.—Chemistry: Mr. Taylor and Mr. Heisch.—Midwifery: Dr. Frere.—Materia Medica: Dr. H. Thompson.—Medical Jurisprudence: Mr. Henry and Dr. Coote.—Practical Chemistry: Mr. Taylor and Mr. Heisch.—Botany: Mr. Bentley.—Histology: Dr. W. Woodham Webb.—Comparative Anatomy: Mr. Flower.

General Fee for attendance on the Hospital Practice and Lectures required by the College of Surgeons and Apothecaries' Company, £81. This sum may be paid by instalments of £35 at the beginning of the first session, £35 at the beginning of the second session, and £11 at the beginning of the third session. For every additional session, £5.

This fee admits the Students to the Practical Chemistry course, and to all other lectures delivered in the College except Comparative Anatomy.

All general Students are required to perform the duties of Clinical Clerks and of Dressers during each winter and summer session, except the first winter session.

RESIDENT CLINICAL ASSISTANTSHIPS.

For the encouragement of Clinical Study, and for the promotion of Clinical Instruction in the Hospital, the Governors have instituted Three Clinical Assistantships, to be awarded on competition to Students who have completed their education in the School. It will be the duty of the Clinical Assistants to observe and record the cases in the Hospital, and generally, in the absence of the Medical Officers, to carry out the treatment directed by them. They will reside and board in the Hospital for one year free of expense.

Two House Surgeons are elected by competition from among the Students who have completed their curriculum, and reside and board in the Hospital free of expense. Fee, Twenty Guineas.

Prizes and Certificates are also awarded to the Students who have most distinguished themselves, at written periodical Class Examinations, in all the subjects of study embraced in the Session.

The Governors' Prize of Twenty Guineas will be awarded to the Student who, having distinguished himself generally by conduct and acquisitions in the College, shall present the best joint Clinical Reports in Medicine and Surgery.

Parents and Guardians who propose sending Pupils to the Hospital may communicate with the Dean, or with Mr. De Morgan, Treasurer to the College, at the Hospital, daily from One to Three o'clock. Information may also be obtained on application to any of the Lecturers, or to Dr. Corfe, the Resident Medical Officer.

All students on entering will be required to sign an undertaking to conform to the laws relating to the discipline of the Hospital and College.

T. W. NUNN, Dean.

The Queen's Hospital, Birmingham.—

A MEETING of the GOVERNORS of the QUEEN'S HOSPITAL will be held on FRIDAY, AUGUST 12th, to Elect an ASSISTANT-PHYSICIAN and an ASSISTANT-SURGEON. The Governors are respectfully requested to keep their votes disengaged until the Testimonials of all the respective Candidates are fairly before them. The Testimonials to be sent in under cover, to the Secretary of the Queen's Hospital, on or before Friday, August 5th, 1859. For information respecting the duties of the appointments, application may be made to the Secretary.

DAVID MALINS, Jun., Secretary.

Norwich Union Life Insurance Society.

Instituted 1808. Invested Capital exceeding £2,000,000 sterling. This Society is one of the very few purely Mutual Insurance Offices, the whole of the profits being divided among the Policy-holders, and possesses large reserves applicable to future Bonuses.

The rates are considerably below those usually charged. Thus, at the age of 40, the sum of £33 19s. 2d., which, at the ordinary premium, will insure £1000, with the Norwich Union

WILL INSURE ONE THOUSAND AND NINETY-FIVE POUNDS EIGHT SHILLINGS,

giving an immediate bonus in addition to subsequent accumulations. Annuities and Special Risks undertaken on favourable terms.

Medical Fees paid by the Office.

For forms of proposal and prospectuses, apply at the Society's Offices, 6, Crescent, New Bridge-street, Blackfriars, E.C., and Surrey-st., Norwich.

Williams and Son's Pure Glycerine

SOAP. Analysed by Dr. Hofmann, F.R.S., and Professor Redwood, Ph.D., strongly recommended by many eminent members of the Medical Profession, and favourably noticed by the following Medical Journals:—

THE LANCET.
THE MEDICAL TIMES AND GAZETTE.
THE BRITISH MEDICAL JOURNAL.
THE MEDICAL CIRCULAR.
EDINBURGH MEDICAL JOURNAL.
THE DUBLIN HOSPITAL GAZETTE.

It is suited to all cases of delicate skin (whether arising from disease or otherwise), and is admirably adapted for nursery use. May be had of all respectable Chemists, Perfumers, etc.

SOAP-WORKS, CLERKENWELL, LONDON, E.C.

ORIGINAL COMMUNICATIONS.

ON THE COMPARATIVE ANATOMY OF THE PONS VAROLII.

By Dr. ROLLESTON,

Lee's Reader in Anatomy at Christ Church, Oxford.

It is commonly stated in works on comparative anatomy that in all mammals save man and the two most anthropoid of the apes, "There lies close behind the pons, near to the pyramidal bodies, a quadrangular elevated layer of transverse medullary fibres which abuts against the origin of the facial and auditory nerves, and is called the trapezoidal body."—Wagner's Comparative Anatomy: translated by Tulk, page 23. Solly on the Brain, page 109. This body is not to be seen as I believe in the bears. In certain uncatalogued specimens in the Museum of the College of Surgeons, including one of *Ursus Syriacus* presented by Dr. Buckland, its presence is not recognisable. As a general rule, however, it is large in the carnivora; and were we not acquainted with the fact of its absence in the bears, we might be inclined to think that the nocturnal habits and consequent need of acute auditory sensibility of these races determined the development of the organ. This interpretation of the meaning of this structure can, however, be no longer considered as tenable. By observation of the relative position of the sixth nerve's superficial origin to the posterior edge of the pons in animals possessing, and in the three or four destitute of a corpus trapezoideum, I have been led to believe that its appearance is not due to an excess but to a defect of development; that when it makes its appearance it does so, not by virtue of any extra prominence of its own, but because it is no longer overlapped and hidden by other superimposed nerve fibres. In man and the orang and smaller chimpanzee (*troglodytes niger*) the sixth nerve arises immediately posterior to the edge of the pons, and indeed seems to bend from underneath it. In animals possessing a corpus trapezoideum, the sixth nerve arises at some little interval posterior to the posterior free edge of the pons. This interval corresponds with the inner end of the trapezoidal space which we thus see is but a strip of medulla oblongata uncovered and overlaid by an excessively-developed pons.

As the bears possess the power of maintaining the erect position to an extent little inferior to that of the anthropomorphous apes, the extraordinary development of their pons is readily explicable by this reference to their habits. For the pons, like other commissures, exists but for the sake of the organs which it brings into physiological unity; and the cerebellar lobes which it thus unites may be shown by an overwhelming amount of evidence from comparative anatomy to be, either as centres for co-ordination of movement, or perhaps more surely as centres for muscular sensibility, indispensably necessary for the performance of complicated muscular efforts. But no muscular effort is of so complicated a character as that which results in the maintenance of the erect position, in none is it so necessary for the mind to have exact information as to the position and state of the muscles.

The impressions thus received in the cerebellar lobes are more exactly and instantaneously brought into harmony and unison by the development of additional commissural fibres in animals which have to maintain either occasionally or constantly, an erect position in such a medium as atmospheric air than it seems necessary they should be in animals either possessed of a wide base of sustentation, as the all but quadruped baboons, in other points so closely allied to the oranges and chimpanzees; or living generally in such a medium as sea water, which relieves them of much of the labour of supporting the weight of their bodies. Highly developed as is the cerebellum of the porpoise, its corpus trapezoideum is yet most manifest—in other words, the commissure of its cerebellum is less extensive, as indeed is its corpus callosum, the great cerebral commissure, than the complicated convolutions of each of the two organs would have led us to anticipate.

Before passing to the second point of this communication, I would remark that the anatomy of the porpoise confirms strongly the views which Schroeder Van der Kolk has propounded as to the relation in which the

olivary bodies stand to the motor nerves of the face muscles. The upper part of these ganglia may be shown to be connected in man with the nucleus of origin of the portio dura, just as their lower part is with the nuclei of the spinal accessory and hypoglossal, and the Dutch anatomist holds that they stand to all the three nerve pairs in the relation of supplementary nerve centres, ensuring perfect and consentient bilateral movement. Now the corpora olivaria in the porpoise are, as is well known, so enormous as to overlap, conceal, and meet over the anterior pyramids. This enormous size is at first sight not easily explicable; man, the apes, and the elephant, possess prominent corpora olivaria; but the porpoise possesses no power of expression like man, none of grimacing like the apes, no proboscis like the elephant; it is not till we think of its blowhole, and recollect that our own nasal muscles are supplied by the portio dura, and have even in ourselves considerable respiratory functions, that we understand how it is that the porpoise has so large a portio dura and so huge a nerve centre for its regulation.

I shall now proceed to show that the human pons has an excess of development on its anterior no less than on its posterior edge, as compared with the analogous commissures of other animals; and to do this, I shall notice the existence of a band of nervous substance, which, so far as I know, has never as yet been described.

In the lower animals, and especially in such as have, like many of the larger herbivora but a narrow pons, the third nerve arises from the crura cerebri, a long way anterior to the anterior margin of the pons. A vertical half-hoop of nerve fibres may be observed running down and into the crura cerebri, which it crosses at right angles, just at the spot where the third nerve is given off. Traced upwards it is found to become connected with the tubercula quadrigemina. It is always easily recognisable in the brain of the sheep, though, like the processus arciformis (of Solly), it is often much better marked in one brain than another of the same species. In some human brains, though possibly not in all, this loop may be found lying overlapped and hidden by the anterior bourrelet of the pons. In a hardened brain, now in the Christ Church Museum, this structure is particularly manifest, its lower end passing into the crura cerebri, near to the exit of the third nerves, and its upper end bifurcating so as to send one branch down and along the pillars of the valve of Vieussens, and the other upwards into the testis.

The ultimate connexions of this band I have not as yet worked out; but I have little doubt that the relation which it seems on a superficial view to hold to the centres of optic sensibility on the one hand, and the oculomotorius nerve, and perhaps others, on the other, will but be confirmed by further research. Its unoverlapped state in the lower animals caused me to notice it just as the similar condition of the corpus trapezoideum has long ago caused it to be described. Its relations to the third nerve seem fixed, and point clearly to an excess of anterior development of the pons, when that structure overlies and conceals it.

The Christ Church Museum possesses specimens of all the lower brains to which I have referred, with the exception of those of the bears, and these preparations I have carefully studied, so as to avoid any chance of falling into error.

SOME ACCOUNT OF DIPHTHERIA AND EPIDEMIC SORE-THROAT,

AS THEY HAVE PREVAILED IN THE PARISH OF ISLINGTON IN 1858-9.

By EDWARD BALLARD, M.D.

Late Lecturer on the Practice of Medicine at the Grosvenor-place School of Medicine; Medical Officer of Health for Islington.

(Concluded from page 55.)

Relation of Diphtheria to Scarlatina.—The following facts may contribute towards solving the problem of the mutual relation of these diseases. In themselves they appear opposed to the hypothesis that they are merely phases of the same malady:—

1st. In 7 cases of Class 1 the diphtheritic sore-throat was stated to have been associated with recent scarlatina. In only 2 of these did the rash appear in the course of the throat affection. Out of the remaining 5 cases in which the

rash appeared first and the diphtheritic sore-throat secondarily to it, the rash had in 4 cases left the skin before the exudation upon the mucous membrane made its appearance. I may add that in other instances that have come under my notice both the rash and sore-throat of the scarlatina have quite disappeared before the symptoms of diphtheria set in.

2nd. In 47 instances, 38 of them being of Class 1, I was able to obtain satisfactory information as to the patient having suffered from scarlet fever at more distant periods. The following represents the proportion of those who had and had not thus suffered:—

—	Had scarlatina previously.	Not had scarlatina previously.	Total.
Class 1	9	29	38
Class 2	1	2	3
Class 3	2	4	6
Total	12	35	47

This proportion of 1 to 3 does not, I imagine, differ greatly from that which would be found to exist among persons selected in any other manner from the same ages and the same stations of life. In the 12 patients who had had scarlatina, the occurrence of the disease was dated back to periods varying from six months to five or six years. Now, few occurrences in Medical experience are more rare than a second attack of scarlet fever: all writers seem to agree in this. Dr. Willan only met with a single instance in 2000 cases, and Bouchut says that he has never met with a well-authenticated case at all. Still, as I desire to state this question fairly, I may say, that, although I have never myself seen a second attack of scarlatina with rash, I have on more than one occasion seen persons who have had scarlatina attacked with sore-throat when attending upon persons suffering from true scarlatina, and this at a period as short as a year from their own attack. This appears to me a new mode of viewing the matter; it is one on which the experience of the Profession should be expressed.

There is a *Polymorphism in Disease*, as in crystallography. Witness the varieties of true and masked agues, the almost identity of small-pox and vaccinia, the undoubted relation of erysipelas and puerperal fever, of regular and irregular gout, of the several forms of cancer, etc. And with respect to scarlet fever, practical accoucheurs know very well the danger to which a puerperal woman is exposed when subjected to the influence of scarlatina poison. An impression has long been growing up in my own mind that there is a form of fever to which they are liable that bears to scarlet fever the same relation that another form does to erysipelas, and that this fever is of a very fatal type. I have seen several such cases in consultation where no rash or even sore-throat have been developed, but where the woman has sunk as under the influence of a powerful depressing poison. I know that true scarlatina with rash may be developed under such circumstances; but what I am now speaking about is a fever without rash, and bearing characters different from ordinary scarlet fever.

It may be that the amount of protection afforded by a previous attack of any of these polymorphous maladies in one shape against an attack in another shape varies from *nil* to something as nearly absolute as can be. It seems to me that this is a point to which scientific enquiry might be usefully directed.

3rd. Just as an attack of true scarlet fever furnishes no protection against an attack of diphtheria, so the following case indicates that diphtheria furnishes no protection against scarlet fever. Three children in a family in my district were attacked with diphtheria in August, 1858. Two of them died; the third, aged 3 years, recovered. I saw these children, and satisfied myself that there was no error in the diagnosis. In January, 1859, the child that recovered was attacked with scarlet fever, after playing about upon a carpet brought from a house where a fatal case of this disease had occurred. There was both the rash and the usual throat affection, but no diphtheritic exudation; and the child died.

4th. Among all the cases, fatal or otherwise, that I have investigated, I have not met with any instance in which diphtheria has appeared to have been communicated from a patient with scarlatina, except where the scarlatina has been

communicated also. Neither have I at present met with more than one instance in which cases of diphtheria and cases of scarlatina occurred about the same time in such a manner as to favour the idea that they were varieties of the same disease.

5th. The mortality from epidemic sore-throat during 1858, if this disease were but a form of scarlet fever, would be expected to have borne some relation to the mortality from the latter disease, and to have fluctuated in harmony with it. Such, however, was not the case, as shown by the following table:—

DEATHS WHICH OCCURRED IN ISLINGTON DURING EACH OF THE FOUR QUARTERS OF 1858.

—	1st Qr.	2nd Qr.	3rd Qr.	4th Qr.
Scarlatina	9	4	34	69
Epidemic sore-throat	5	15	22	15

The greatest number of deaths from epidemic sore-throat occurred in the third quarter of the year, but from scarlatina in the fourth. The number of deaths from epidemic sore-throat was the same in the second and fourth quarters, while in the former there were only 4 from scarlatina, and in the latter 69.

I may add that as scarlatina declined in the first quarter of the present year, the deaths from epidemic sore-throat (nearly all diphtheria) increased. Thus there were registered 29 deaths only from scarlatina, but 20 from epidemic sore-throat.

Again, the greatest mortality from scarlet fever occurred in the six weeks from October 17 to November 27. During this period 48 persons died of scarlet fever, but only 5 of any form of epidemic sore-throat, and during four of those weeks, viz. from October 24 to November 20, no patient died from epidemic sore-throat. When, however, the mortality from scarlet fever was checked, as it was most remarkably, on the occurrence of the very severe cold about the 26th of November, the deaths from epidemic sore-throat reappeared in the returns.

Relation of Diphtheria to other forms of Sore-throat.—The prevalence of sore-throat not diphtheritic in character during the past year, has been matter of general remark. Many, if not most, of these throats exhibited some approach to the colour of the mucous membrane when about to become the seat of diphtheritic exudation. These sore-throats appear to bear the same sort of relation to diphtheria as diarrhoea bears to cholera in epidemic seasons. Just as in any cases of diarrhoea in an epidemic period, it is impossible to predecate that it will not pass into cholera, if neglected, so, in the ordinary sore-throats which have lately presented themselves, no one would be bold enough to assert that any one might not before long exhibit the characteristic symptoms of true diphtheria. A fact upon which I would especially rely in support of this view, is the occurrence of non-diphtheritic sore-throats equally with diphtheritic sore-throats among the members of families where deaths from diphtheria had taken place. Out of forty-seven families in which a death from diphtheria occurred (Class 1),

	Families.
Some other members of the family suffered from diphtheria in	9
From other forms of sore-throat, in	15
Some members suffered from diphtheria, and others from sore-throat, in	8
Neither diphtheria nor sore-throat occurred in other members of the family, in	15
	47

The severity of these cases of sore-throat varied considerably. In some, it was a slight attack, lasting but a few days; in others, there was so much febrile disturbance as to demand Medical assistance; in others, again, there was ulceration, suppuration of the tonsils, or sloughing of some of the tissues. In some families the earlier cases were of sore-throat, in others the earlier cases were diphtheritic.

Is Diphtheria an Infectious Disease? I will state the facts which incline me to the affirmative.

1. A *primâ facie* case appears made out by the facts mentioned in the last section. Infectious diseases habitually spread in families they invade. Out of forty-seven families there were only fifteen in which the other members all

remained healthy. Of course it may be argued, in opposition, that all the members of a family are equally exposed to the operation of local causes of disease.

2. As a rule, it spread in the houses it invaded chiefly among those members of the several families who were most closely in communication.

3. In no case where separation from the sick person has been effected early in the disease have I noticed that it has spread to the separated individuals. In one case where communication had been allowed for three days before separation, a child was seized with diphtheria on the sixth day of removal from home.

4. The following special instances may be adduced of communication of the disease from one house to another, viz. :—

Jane J. aged 10 years, resided at Islington, with her mother, an aunt, and three sisters. On May 1 and 2 she was on a visit at the house of an uncle, whose daughter, Jane's cousin, was kept at home because she was believed to have a cold. On the 2nd this child exhibited decided symptoms of diphtheria; the attack was slight, and she recovered. On May 6 a servant in this house was taken ill with a severe attack of diphtheria, recognised as such by the Physician at St. Bartholomew's Hospital, to which she was removed, and where she died. On the 2nd, Jane returned home, was taken ill on the 3rd with diphtheria in a severe form, and died on May 9. Her mother, and a sister aged 14 years, were both taken ill on May 11. She had not been so much with her daughter as other members of the family up to the 8th, when she sat up with her all night. She was of a highly nervous temperament. The tonsil sloughed, and there was a complete cast of the trachea expectorated. She died on the 18th. The sister, who was also attacked on the 11th, slept with her mother, and when not at school was continually in and out of Jane's room, sitting there sometimes for hours together. She died on May 14, asphyxiated. Another elder sister who slept with Jane and the aunt, suffered from nothing but a slight sore-throat.

On September 18, George B. aged 2 years, was attacked with what was believed to be diphtheria. He was an obstinate child, and the throat could not be fairly inspected. The tissues, however, under the jaw were swollen, and there was difficulty in swallowing; the breath became fetid, the voice lost, there was great dyspnoea, and a discharge from the nose. He died on the 24th. His brother, Edward B. aged 9 months, was attacked on September 22, that is, on the fourth day of George's illness. In this case the diphtheritic exudation was marked; there was great external swelling, great dyspnoea, fetor of breath, and bloody discharge from the nose, and from the first the child refused the breast. He died also on the 24th. The father and mother both suffered from sore-throat, being attacked on the 25th. A grandmother also had sore-throat on the 24th, 25th, and 26th. She laid out the children on the 24th, and immediately returned to her own residence in another part of the parish. A child who lived with her, aged 16 months, a cousin of those that died, was seized with sore-throat and fever on the 29th. I saw him on October 4. There was then the diphtheritic membrane commencing upon one of the tonsils. He was attended by a general practitioner in the neighbourhood, and died on the 19th.

About the middle of May sore-throat began to prevail in a large school in Islington. One of the boys, who had just returned home to Kingsland for his holidays, was seized with diphtheria on May 23 (Whit Sunday). The attack was characteristic, and he recovered with difficulty. On June 5, a boy, aged 9 years, who had not returned home, was attacked with true diphtheria, accompanied by laryngeal complication, and died on the 8th. On June 9, another boy, who was on a visit with some friends for his holidays, was seized with diphtheria; the exudation was well marked, and in consequence of the laryngeal complication, tracheotomy was performed, but he died on the 12th. The sanitary arrangements of the school were not objectionable; the drainage good, and the water-cisterns regularly cleansed. On June 15 another boy returned home from the school with diphtheria. Previously to his return all the family were in good health. Early in July a sister, aged 2 years, was attacked with diphtheria in a marked form, and died on July 22. A brother also was attacked with diphtheria and recovered, and three female servants also had slight attacks. Another sister had an attack of sore-throat. An infant and the father and mother all escaped.

A little girl, aged 6 years, went to a day-school. A child belonging to the lady that kept the school was ill with diphtheria. On March 3, the little girl was attacked, and I saw her twice in consultation. The exudation was well marked and extensive. She died from prostration on March 24. The father and mother both suffered subsequently from a slight attack of sore-throat. A brother of the patient, who was carefully kept apart from her and ultimately sent away from home, escaped. In this instance, however, there was a local source of disease in a very defective condition of the drainage of the house, and the water-cistern was disgustingly foul.

The connexion of Epidemic Sore-throat with Local Causes of Disease.—The following table exhibits the results of inquiries instituted at fifty-seven houses where fatal cases occurred :—

	No. of Houses.	House damp, offensive smells, or defective drains.	Overcrowding or defective ventilation.	Foul drinking water and other nuisances or noxious accumulations.	Nothing discovered amiss.
Class 1 ...	46	19	4	6	20
Class 2 ...	6	3	3
Class 3 ...	5	2	..	2	2
Total...	57	24	4	8	25

In more than half the houses, then, which were examined, there was some defect or other in the sanitary arrangements, or in the surrounding conditions of the patient. In the greater number of the houses thus deficient, the fault was discovered in the state of the drainage.

CASES OF ACUTE NECROSIS FOLLOWED BY PYÆMIA.

By WILLIAM H. STONE, M.B. Oxon, L.R.C.P.
Medical Registrar to St. Thomas's Hospital.

(Concluded from p. 57.)

Case 3.—T. B. aged 15, apprentice; admitted Jan. 13, 1858. Was brought in, and said to be suffering from fever. At first taken to a surgical ward, but attention not being drawn to the leg, and the symptoms closely resembling typhoid fever, was ordered by the Surgeon to be removed to the Physician's ward. When brought in to King's Ward, it appeared from the information of some friends, that he had been perfectly well, and at work until a month before admission. On that date he had fallen down some stairs, and inflicted a slight injury on the left leg. An abscess formed in the injured spot, from which the discharge had been very profuse. Subsequently, but without definite commencement, feverish symptoms set in, which had continued until his admission. When first seen, he had the aspect of one suffering from continued fever. The face was flushed, the skin hot and dry; pulse 124, feeble; tongue thickly furred on the dorsum; sordes on the teeth. The respiration was normal; the physical signs not unhealthy. The patient was partially sensible, and answered questions with hesitation.

The left leg was intensely tender; and there was remarkable surface-tenderness all over the body. On the front of the leg, about the middle of the tibia, was a small opening, large enough to admit a quill; from this there was profuse, fetid purulent discharge. A probe passed into this opening, could be pushed its whole length upwards or downwards without encountering resistance. It scraped on exposed bone the whole distance.

On the 15th he was much in the same state; but pressure on the left side, or movement of the left arm, seemed to cause intense pain.

On the 20th he was worse. He was sensible in the day, but delirious towards night. Pulse 118, feeble; much collected sordes on the teeth. No form of exanthematous eruption to be detected. Skin very hot and sweating. Diarrhoea had been coming on for a day or two, profuse, fetid, and black in colour; motions passed in the bed.

On the 23rd the diarrhoea and other symptoms continued unabated and unchanged.

On the morning of the 26th he died, apparently from

exhaustion; the faculties having continued tolerably unimpaired to the last.

Post-mortem examination, thirty-five hours after death. Body very emaciated; two or three small openings over the left shin, whence pus exuded on pressure. On laying open the left leg, the whole shaft of the tibia was found denuded, and bathed in much dark green foetid pus. The shaft was almost entirely free of periosteum, of a whitish hue, here and there slightly worm-eaten and eroded. The epiphyses, knee and ankle-joints were healthy. On making a longitudinal section of the shaft, the upper and lower thirds of its cancellous structure appeared infiltrated by a yellowish material like softened fibrine. The infiltration was not uniform, but extended in irregular bands, surrounded and separated by highly congested tissue. The central third of the cancellous structure had a perfectly healthy appearance. There was no trace of deposit of new bone. The necrosis was clearly at once acute and complete; for the healthy-looking portions in the middle were quite cut off from vascular supply. The veins of the thigh were healthy. Calvaria, dura-mater, and arachnoid healthy. There was a little blood effused in the subarachnoid tissue over the posterior lobe of the left cerebral hemisphere, and over the greater part of the cerebellum; the fluid in the rest of the subarachnoid tissues was healthy looking. There was an abscess, about the size of a horsebean, in the substance, but close to the surface of the right cerebral hemisphere, corresponding nearly to the position of the parietal eminence; and three or four about the size of tares were discovered in different parts of the brain. They contained thick greenish pus, and their parietes were soft and ill defined. No abscesses were found in the part corresponding to the subarachnoid sanguineous effusion. The substance of the brain generally was slightly congested, but healthy-looking; there was no apparent disease of its vessels. Pericardium healthy. Heart of usual size; muscular tissue pale, but firm. Two of the musculi papillares were covered by a pretty firmly adherent layer of false membrane. On cutting into these, a little softened muscular tissue, apparently infiltrated with pus, was discovered immediately beneath the serous membrane, and a considerable portion of the entire thickness of the ventricular walls immediately below the aortic valves was similarly disorganised. All the valves were healthy. There were old adhesions in both pleuræ, but more especially in the left: here and there on the surface of the right lung was an exceedingly thin film of lymph. The left lung was crepitant for the most part, though œdematous. In the upper lobe, towards the outer side, near the surface, was a patch of pulmonary apoplexy about as large as a filbert, in the centre of which were two or three suppurating points, from the size of a tare to that of a grain of wheat. In the upper part of the right lung was a mass of diseased tissue about two cubic inches in bulk. The lower part of this formed an abrupt margined cavity, filled with a brick-red pulpy material, adherent to the parietes, and consisting evidently of disintegrated lung tissue infiltrated with pus. The remainder of the diseased mass was composed partly of carnified, partly of distinctly apoplectic tissue, studded with yellowish spots of suppuration from the size of a pea downwards. There was a similar mass at the lower part of the lower lobe. Close to the surface of the anterior portion of the upper lobe was a small abscess about as large as a hazel-nut. The remaining portions of the lung were œdematous and congested, but otherwise healthy. Bronchial tubes healthy. Bronchial glands large, containing a considerable quantity of firm cheesy tubercular deposit. Peritoneum for the most part healthy. The liver was of ordinary size, and perfectly healthy throughout. A small portion of its surface, in relation with the right kidney, formed part of the walls of an abscess. The upper part of the spleen was attached by soft recent adhesions to the diaphragm. On removing the spleen it was found of usual size. The adherent portion formed a patch about an inch by two inches in size, of a pale yellow colour, with a soft flocculent surface, the margins forming an abrupt elevated rim of adhesions bounding a small abscess. The spleen tissue in this part was diseased for a distance of one or two inches. It was abruptly margined, softer, more elastic, and more juicy than ordinary fibrinous masses; had a buff colour tinted with pink, and in several places contained cavities filled with a pulpy puriform material. Several yellow masses of the size of a pea and less were discovered in different parts of the organ, and proved to be small abscesses. The

tissue in other parts was rather dark and soft, but tolerably healthy. Pancreas, stomach, and small intestines healthy. In the cœcum were a few small recent ulcers of irregular shape, with unthickened edges. The left kidney was of usual size. Its surface beneath the capsule thickly but irregularly studded with roundish yellow projecting points from the size of a tare downwards, surrounded by a broad rim of congestion. On section many small abscesses were discovered, those in the medulla radially elongated. The kidney substance between was pale and healthy. The right kidney was in a more advanced stage of the same condition, its capsule separated from the organ in several places by accumulations of pus, one of which amounted to about an ounce. Other organs healthy. On microscopic examination of the fluid from the heart and kidneys, it was found to be pure pus, mixed with broken-down muscular and glandular tissue in the respective cases, and with minute oily molecules. The deposit in the spleen consisted of cells much resembling pus, but more granular, irregular as to size, and not distinctly acted on by acetic acid.

On reviewing these cases, one or two points of interest present themselves besides those mentioned in the outset. The first of these is, the causeless and idiopathic nature of the ailment. In two of the three cases there was absolutely no assignable cause to be discovered; in the third it was only trifling, and such as would be, in the vast majority of cases, quite incompetent to produce so formidable a result. Nor did the autopsy show any predisposing cause, at least in the two most acute cases, where, besides the results of pyæmia, the organs were all perfectly healthy. In the third the presence of tubercle in the bronchial glands would suggest a scrofulous diathesis; yet, even here, the deposit was small, quiescent, and far removed from the seat of mischief. In two of the cases the shortness of the whole illness is remarkable; in the first, five days, in the second, sixteen days intervening between a state of complete health and death. It is probable that even in the third about four weeks would comprise the whole duration of any serious mischief.

In the post-mortem examinations the extent of the local destruction is worthy of comment; the lower third of the radius, the lower two-thirds of the femur, and the whole shaft of the tibia are in the several cases involved.

Small masses of pulmonary apoplexy appear in the lungs in all the cases. In the first and third this condition has run on to the formation of abscess; in the second we have only the hæmorrhage, which, as co-existing with abundant evidence of suppuration in other organs, we seem justified in regarding as an early stage of the same morbid process.

In all the cases there are abscesses of the kidneys; in two the muscular substance of the heart is infiltrated with pus, and more or less disorganised. In two cases, also, the muscular veins of the affected limb are stopped by adherent and decolorised clot, mixed with puriform fluid. In the first case this condition is also observed in the branches of the pulmonary artery leading to the apoplectic effusions. In one case the spleen is the seat of several purulent collections. The liver, in two cases, exhibits an appearance not fully explained, but frequently seen under such circumstances. To this Dr. Bristowe, in the *Pathological Society's Transactions*, has already directed attention.

PUBLIC HONOURS TO A PUBLIC BENEFACTOR.—On Saturday the whole of the shops and other places of business were closed in South Shields, between one and three o'clock in the afternoon, during the funeral of the late Dr. Winterbottom. The whole of the vessels in the lower reaches of the Tyne had their flags half-mast high also. The funeral took place in the New Cemetery, and at least 10,000 persons were present. The remains of the venerable old man were followed to the grave by the mayor and corporation, the members of the Mechanics Institute, the seamen and shipwrights of the port, Odd Fellows, Foresters, etc. It has been already stated that Dr. Winterbottom was the oldest member of the Medical Profession, and was well known for his philanthropy. After the payment of a few legacies, the remainder of his fortune (amounting to about £22,000) has been left to trustees, to establish a marine school or college in South Shields, for the education of seafaring men, free of cost, in nautical astronomy and the higher branches of navigation.

THE LONDON
PRACTICE OF MEDICINE AND SURGERY.

WESTMINSTER HOSPITAL.

DEATH FROM CHLOROFORM.

ON Monday last (18th) a death from chloroform occurred at the above institution. The patient was a man, aged 45, who required incisions to be made in his penis and scrotum on account of extravasation of urine.

One drachm of chloroform was placed in the inhaler ordinarily used in the Hospital; but the inhalation of this quantity only produced partial anæsthesia. Half-a-drachm more was then added, and the patient seemed to pass comfortably into a state of unconsciousness. Mr. Holt then made the required incisions, which occupied about a minute, the inhaler having been removed just as he began to use the knife. Just as the operation was completed, the pulse, which had been watched by Mr. Trend, the clinical assistant (who administered the chloroform with great care), ceased entirely, with only a slight preliminary fluttering. The respirations continued for a minute or two, and it was attempted to aid them by Marshall Hall's process; and as soon as they ceased tracheotomy was performed, and artificial respiration was kept up for more than half-an hour, by means of Dr. Marcet's apparatus. Galvanism, and the other usual restorative measures were employed, but in vain; the pulse never returned. At the time that the first evil symptoms occurred, the breathing was going on well, and there was no congestion of the face. Failure of the pulse, and livid paleness were the first indications of danger, and afterwards the breathing became weak and flurried. No convulsive movements occurred.

The post-mortem examination was made, on the following day, by Mr. Power, Assistant-Surgeon, and Dr. Anstie, Curator of the Pathological Museum. The body was large and well-formed, but excessively loaded with fat. The rigor mortis was present to a moderate extent; the blood was everywhere quite fluid.

The lungs presented precisely the appearance which might have been expected after a prolonged use of artificial respiration, viz. slight distension of the air-cells, and considerable congestion in various parts. Otherwise they were quite healthy, and certainly had not been gorged with blood at the time of death. The heart contained a good deal of fluid blood, pretty evenly divided among its several chambers, but it could hardly be said to be "distended." Its muscular walls are very thin; and the muscular tissue was of a pale fawn colour, and extremely soft and friable. It was possible easily to push a finger through the wall even of the left ventricle. Portions of the muscular tissue of each auricle and ventricle were submitted to the microscope by Mr. Power and Dr. Anstie, and the existence of fatty degeneration, in a very high degree, was at once evident. The kidneys were found to be similarly affected, the convoluted tubes being full of granular molecules of fat. The brain was remarkably healthy, and presented no traces of congestion.

The following remarks have been appended to the history of the case by Dr. Anstie:—

"There can, of course, be no doubt that death was occasioned, in this instance, by paralysis of the heart. The important questions which remain for us are these:—1. Did the existence of such fatty degeneration as was present render cardiac palsy inevitable if chloroform were given? 2. Ought the existence of that condition to have been known to the administrator before giving the chloroform? 3. Was every precaution used in the administration?"

"To the first of these questions we may answer, that it is impossible to say what amount of fatty degeneration of the heart contraindicates the use of chloroform. I myself have given it successfully in many cases where there is every reason to believe this affection was present. With regard to the possibility of always detecting the disease, every one knows that our diagnostic means are most unsatisfactory and insufficient for the purpose. Lastly, I am certain that every care was taken, in the administration itself, as regards the use of a moderate quantity of chloroform, the gradual induction of anæsthesia, etc., etc.

"I cannot help calling the attention of administrators of chloroform to the constantly increasing evidence which we are receiving, to the truth of Snow's doctrine, that death occurs in case of surgical anæsthesia, from paralysis of the heart. I am as well aware as anyone that it is possible to kill animals, or men, with chloroform by the way of apnoea; but I am satisfied that this never occurs in surgical practice. And I would beg everyone to remember that the legitimate corollary of this proposition is, that it is highly unsafe and improper to administer chloroform except with such an apparatus as provides (by equalisation of temperature and regular admixture of air) for the inhalation of an atmosphere of known and uniform strength. In the case of young children, it is not always possible to use a regular instrument, but they are fortunately much less liable to the fatal accident of carthiac paralysis than are adults."

THE PROVINCIAL
PRACTICE OF MEDICINE AND SURGERY.

THE HULL INFIRMARY.

COMPOUND FRACTURE OF THE SKULL,
TREPHINING, ETC.

(Under the care of Dr. LUNN.)

[Reported with Remarks by Mr. C. J. EVANS, House-Surgeon.]

MARTIN B., aged 10, was admitted on October 13, having fallen on his head from the deck into the hold of a vessel, a height of about twelve feet. His fall was broken by his coming in contact with a beam in his descent. On admission he was insensible, and slightly convulsed on the left side. Extremities cold; considerable hæmorrhage from right ear; no scalp-wound, but extensive tumefaction over the right side, rendering the detection of any depressed bone very difficult. Pupils act naturally.

Right side of head shaved, and cold applied. Ol. terebinth cruribus appl.

9 p.m.—Some slight improvement in the symptoms. He calls out when meddled with. Hæmorrhage from ear continues; urine withdrawn by catheter. Consultation held, and operative interference considered uncalled for at present.

October 14.—A restless night. Pulse 86, soft. Pupils act; swelling on head less; a little blood still oozes from the ear; bowels open, and urine free; extremities warm. He remained much in the same state during the day. Vespere.—The flow of blood from the ear has ceased, but there is a scanty serous discharge. There is a tendency to contraction of the pupils. He takes a little nourishment, brandy in sage, etc.

15th.—Passed a very bad night, throwing himself about and screaming out. Watery discharge from ear much less (it soon afterwards ceased to flow). Passes his stools and urine unconsciously. Left eyelid rather less closed than the right; pupils more dilated; motion and sensibility of left only a little impaired. He very frequently calls out loudly, and always if touched on the head.

16th.—Tumefaction of scalp quite subsided, with exception of a spot behind the ear, which feels boggy.

R. Calomel gr. ij statim sumend., et rept. gr. j. 3tia quaquâ horâ.

R. Mist. sal. simpl. ꝑviij., vini antim. potassio-tart. m xi. M. cap. ꝑj. 3tia quaquâ horâ.

17th.—Passed a very restless night. An exploratory incision was made through the soft swelling behind the ear. There was no fracture at that spot, but nearer the ear was a perpendicular fissure extending upwards towards the vertex, and downwards towards the base. It was nearly a line in width, and the cerebral membranes protruded through it. A slight fissure extended from this forwards. A triangular portion of bone was removed with Hey's saw, but there was no marked depression. During the struggles of the patient some coagulated blood, and a little cerebral substance were forced through the opening in the skull. Wet lint applied.

18th.—Was restless for a time after the operation, but since has been much quieter. Stools and urine passed under him. Pulse of moderate volume. Takes any nourishment that is offered him. To omit the calomel.

24th.—Has remained much the same since last report up to the present time. He now lies on his back without attempting to move. Right pupil dilated and motionless; the left acts; tendency to strabismus. Complete loss of motion, but not of sensibility on left side. Takes a little nourishment, but he appears gradually sinking.

27th.—He picks at the wound on his head, and has become restless again; is to a certain degree sensible, and speaks occasionally when spoken to. A fungoid mass of coagulum and cerebral matter protrudes from the wound. Charpie applied and cotton wool.

30th.—There is a marked change for the worse. He lies perfectly motionless and insensible. Pupils much contracted; pulse in the morning frequent and full, towards evening scarcely perceptible. He died at 7 p.m., seventeen days from the date of the accident.

Autopsy, fifteen hours after death.—The fracture extended upwards nearly to the sagittal suture, then passed forwards toward the coronal suture, and finally joined the small fissure before spoken of, thus isolating a portion of bone, which was not however depressed. On reflecting the dura mater on the right side, a quantity of healthy-looking pus escaped (about four ounces), which had compressed the hemisphere. This latter itself was bloodless on section, and at the seat of the hernia cerebri was quite disorganised. The left hemisphere appeared quite healthy, but the cerebellum was paler, and much softer than natural. The fracture extended downwards quite through the petrous bone in a longitudinal direction, and terminated rather abruptly on its anterior surface. No other organs were examined.

Remarks.—There were no marked inflammatory symptoms during life, but they were rather those of irritation, as from a spiculum of bone penetrating the brain, and with this idea it was that the operation was performed, for the purpose of removing any irritating substance that might be found. This case is another among many instances showing the obscurity which so often exists in some injuries of the head. The hernial protrusion probably prevented the pus from escaping from beneath the dura mater.

THE LONDON AND PROVINCIAL HOSPITAL PRACTICE.

OPERATIONS FOR STONE IN WOMEN.

BEFORE following up the recent Statistical Analyses which we have given of lithotomy and lithotripsy cases in the Metropolitan and Provincial Hospitals, by a general *resumé*, we purpose to devote a short report to the cases of stone in the female sex, which have come under notice during the same series of years. The great ease with which the interior of the bladder in women is reached, renders the treatment of stone in the female sex a matter totally different as regards risk, from what it is in men. Indeed, under most circumstances, it may be said to be almost without risk as far as life itself is concerned. The Surgeon has chiefly to dread the permanent incontinence of urine which is so apt to follow dilatation or section of the female urethra, and to the prevention of this source of misery he devotes all his skill rather than to the obviating of the yet graver dangers which attend the operation in men. As cases of stone in the female are rare, we have but a few cases to adduce in this class. Instead, therefore, of merely tabulating them, we shall give a few particulars respecting each, arranging them in the order in which they occurred, and grouping the London and Provincial cases together.

STATEMENT OF TWENTY-FOUR CASES.

Case 1.—St. Thomas's: Mr. Le Gros Clark.—A stout woman, aged 57. Symptoms for about a year, but not of extreme severity. The urine had never contained blood. Under the influence of chloroform, a Weiss's dilator was used until the urethra would admit the finger. A pyriform stone two inches and a-half in circumference was removed. Recovery, with perfect control over the bladder and urethra. *Case 2.*—Guy's: Mr. Bransby Cooper.—A girl, aged 10. The stone was very large and irregular, and also very hard. It was broken before removal, but free incisions were also required before it could be got away. It was of the mul-

berry kind. The patient recovered, but had incontinence of urine as long as she remained under notice. *Case 3.*—King's College.—A woman, aged 28, in whom calculous matter had been deposited around a hair-pin which had been introduced into the bladder. The bent form in which the pin was, much impeded the extraction. A lateral incision was required. Recovered, but with slight incontinence of urine.

Case 4.—Guy's: Mr. Hilton.—A very delicate girl, aged three and a-half, who had suffered from stone almost from birth. She had constant dribbling away of urine. The stone was large, and incisions were made in each side the urethra downwards and outwards. She recovered well, and after the first day or two was wholly free from incontinence. The stone was a mixed one, but consisted principally of lithates (for full details see *Medical Times and Gazette* for July 29, 1854).

Case 5.—The Bristol General Hospital.—A girl, aged 10, for more than a year the subject of stone. The urethra was dilated and the stone seized, but as it could not be extracted an incision was made in the direction upwards. The calculus was nearly as large as a walnut, and consisted of lithic acid coated with phosphates. The child recovered, but had occasional incontinence as long as she remained under observation. *Case 6.*—The Bristol General Hospital.—A girl, aged 15, for long the subject of stone. Two incisions upward were necessary before the stone could be got away. It appeared to have been adherent. On two occasions on the third day severe secondary hæmorrhage took place, the loss being so great as to induce alarming faintness. The girl recovered perfectly, but up to the last report (one month after the operation) she still had some little incontinence of urine. The stone removed was as large as a bantam's egg.

Case 7.—St. Bartholomew's: Mr. Stanley.—A woman, aged 41, who had suffered severely for upwards of six months. The urine contained pus in large quantities. The urethra was dilated by a Weiss's dilator, until it would admit the forefinger, the process occupying about five minutes. The stone, which was the size of a damson plum, was easily seized and extracted. The patient had rather a sharp attack of cystitis during the week immediately following the operation. She recovered perfectly and without the slightest incontinence of urine.

Case 8.—St. George's: Mr. Prescott Hewett.—A woman, aged 27, was admitted, having impacted in her vagina a bottle neck with a cork in it. It had been in its position for eleven years, and had cut its way through into the bladder, where a large calculous concretion had formed. Mr. Hewett removed the foreign body, and also scraped out an enormous quantity of calculous matter from the interior of the bladder. She recovered, but with the ulceration between the bladder and rectum remaining as a permanent fistula. *Case 9.*—The Marylebone: Mr. Thompson. A girl, aged 9, in good health, in whom the symptoms had been present only three months. Dilatation by sponge tents was practised until the urethra could admit an ordinary sized lithotrite. The stone was then freely crushed. All its fragments came away within twenty-four hours of the crushing, and the symptoms ceased. No incontinence of urine remained. The constituents of the stone were lithic acid and lithate of ammonia.

Case 10.—The Westminster: Mr. Hillman.—A girl, aged 5, in good health. The calculus was large, and an incision was required before it could be removed. The recovery was complete, and not the least incontinence remained. *Case 11.*—Guy's: Mr. Cock.—A girl, aged 6, in good health. The urethra was dilated until it would admit the forceps, and the stone was then seized and held firmly forwards, while the urethra was notched on each side to an extent sufficient to permit of its extraction. The stone broke, and was taken away in two parts. It was about the size of a damson plum, and had a long neck; which had doubtless been moulded in the urethra. A catheter was retained in the urethra, and the vagina supported by a plug of sponge. The incisions healed by first intention, and not the slightest incontinence of urine remained. *Case 12.*—The Middlesex: Mr. Shaw.—A woman, aged 30, the subject of diseased hip-joint, and who had also suffered from stone for two years. The stone was very large. The urethra was dilated to the utmost by Weiss's instrument, and incisions were then practised both laterally and vertically. The extraction required much force. The stone weighed no less than five ounces. No sloughing followed, and the incisions quickly healed. Incontinence of urine remained, and various contrivances had to be resorted to to diminish it. *Case 13.*—The Middlesex: Mr. Moore.—A woman, aged 30, who had suffered for six years from the

symptoms of stone. Lithotripsy had been performed several times. A Weiss's dilator was used, and a stone weighing an ounce was removed without having recourse to incisions. The patient did well afterwards, and had perfect control over her bladder. *Case 14.*—University College: Mr. Erichsen.—A girl, aged 3½, who had suffered severely for some months. The stone was discovered with difficulty. Sponge-tents were used for a few hours before the operation. A bivalve dilator was employed for a few minutes before the extraction. The stone was flattish, and about the size of a shilling. It was removed without either incision or laceration of the urethra. The child recovered well, and not the slightest incontinence of urine remained. *Case 15.*—King's College: Mr. Fergusson.—A girl, aged 10, in good health. Symptoms of stone for two years; but of great severity during the last six months. Three months before she had voided a calculus the size of a filbert. Mr. Fergusson detected a large stone remaining, and at two operations with the lithotrite succeeded in crushing and removing it. The fragments were removed at the time of the crushings. A week's interval was allowed between the sittings. She recovered well, and had no incontinence of urine. *Case 16.*—The Brighton Hospital: Mr. Lowdell.—A woman, aged 34, the subject of vesico-vaginal fistula, consequent on an instrumental labour seven months before. There was also a stone in the bladder. After dilatation with Weiss's instrument the calculus was extracted with a small pair of forceps. Recovered well. *Case 17.*—University College: Mr. Erichsen.—A woman, aged 26, was admitted on account of a very large calculus in the bladder. Symptoms of stone had, from the history, been present since childhood, but the existence of one had not been suspected until during her first confinement, when its large size was found to be an impediment to the passage of the child's head. Craniotomy was necessary to delivery. After her confinement the woman sank into a feeble state, and had great irritability of the bladder. It was three weeks afterwards, that Mr. Erichsen operated for the removal of the stone. Lithotomy by free incision downwards into the vagina was the plan selected, and the stone was easily got away. Death from exhaustion followed on the eighth day. At the autopsy the wound was found in a healthy condition. Both ureters were much dilated, and the left kidney had been quite destroyed by old disease. *Case 18.*—Guy's Hospital: Mr. Cock.—A woman, aged 48, was admitted suffering most severely from symptoms of stone in the bladder. She had almost constant incontinence of urine. A large stone having been detected, the urethra was dilated (by a bivalve instrument), until it admitted the forefinger. Forceps were then introduced, and the stone, a soft phosphatic concretion, was crushed, and extracted piecemeal. The bladder was afterwards syringed out, and appeared to have been quite cleared. For a few days the incontinence persisted, but it afterwards gradually ceased; and at the time of her discharge the woman was well in every respect, except that her urine occasionally escaped during sleep. It is an interesting addendum to this case that the same patient had been under treatment in St. Bartholomew's about two years before, on account of calculus in the bladder and vagina, the concretion, of hour-glass shape, being connected through a vesico-vaginal fistula high up. Large portions of the stone were removed, but not the whole of that occupying the bladder. When admitted under Mr. Cock's care, there was no concretion in the vagina, and the fistula could not be found. *Case 19.*—Guy's Hospital: Mr. Hilton.—A girl, aged 18, in good health, sought admission in June, 1856, stating that four months before she had passed a hair-pin into the bladder. Since the occurrence she had suffered from all the symptoms of a foreign body in the bladder, and these had gradually increased in severity. The pin could be felt on examination per vaginam. In the bladder itself, however, nothing but a mass of calcareous concretion could be felt. An incision having been made in one side of the urethra, the pin was seized, and after having been cut through by forceps this part was extracted. By a little management, the other part was afterwards removed without any further incisions being needed. The concretion which had formed around it, was crushed, and removed piecemeal, about two ounces of fragments being taken away. The patient recovered well, but occasional incontinence of urine remained. *Case 20.*—The Glasgow Royal Infirmary.—A woman, aged 60, was admitted

on account of stone in the bladder, of which the symptoms had been present for a year and a-half. We have no particulars as to how its removal was effected. She recovered well afterwards. *Case 21.*—Addenbrooke's Hospital, Cambridge: Mr. Humphry.—A healthy girl, aged 6, had been suffering from stone for two years before her admission. The urethra was dilated by large bougies until the lithotrite could be introduced, and with the latter the stone was crushed. The first crushing was on January 3, 1857, and the second on January 14. Many fragments passed away, and on the 20th no stone could be found on sounding. No incontinence remained. *Case 22.*—The Brighton Hospital: Mr. Furner.—A woman, aged 34, in very bad health, was admitted with a large stone in her bladder. Symptoms had existed from childhood. The stone after removal weighed fifteen drachms. She sank a few days after the operation. *Case 23.*—The Leeds Infirmary: Mr. Teale.—A woman, aged 48, who had suffered from stone for eighteen years. The urethra having been dilated by Weiss's instrument, the forceps were introduced, and a phosphatic calculus weighing five drachms, was removed. On the seventh day the woman could hold her urine, and her recovery was subsequently complete in every respect. *Case 24.*—The Norfolk and Norwich Hospital: Mr. Cadge.—A woman, aged 50, who had suffered intensely for many months. Dilatation was effected by Weiss's instrument. The stone proved to be very small, weighing only four grains. She left the Hospital with perfect control over the functions of the bladder.

SUMMARY AND REMARKS.

We have, then, in the above collection of cases, 24 instances of operations for stone in the female bladder. Of these, 16 occurred in the practice of Metropolitan Hospitals, and 8 in that of Provincial institutions. Of the whole, 22 cases resulted in recovery, and in 2 the patients died. In both the cases which ended fatally the patients were adults, who had suffered from stone from early childhood, who were worn out by the irritation, etc. produced, and in whom the stone was of very large size.

AGE AT WHICH STONE IS MOST FREQUENT IN FEMALES.—In employing our series of cases to determine the age at which vesical calculus most frequently occurs in the female sex, 5 cases (Nos. 3, 8, 16, 18, and 19) must be excepted. In two of those the concretion had formed on hair-pins intentionally introduced into the urethra, and in the others it was consequent on certain injuries to the vagina to which the adult only is exposed. Taking, then, the remaining 19 cases as our basis, we find a remarkably close correspondence between females and males, in the period of life most liable to idiopathic vesical calculus. In 6 of the cases, the patient was under ten years of age; in 4 between ten and twenty-five; in 5 between twenty-five and forty-five; and in 4 between forty and sixty. The proportion of cases in which children are the subjects of stone, would be increased if we were to count as such the subjects of cases 17 and 22, in whom symptoms had existed from early childhood, although they were not operated upon till adult age. Probably one or two other of the adult cases ought, in like manner to be counted with the children, if their real history were known. The facility afforded by the female urethra for the escape of small calculi, which, if allowed to remain would have constituted the nuclei of larger ones, is the reason usually assigned for the comparative rarity of cases requiring surgical relief. For anything which can be adduced in proof of the contrary it is a correct explanation, since we have no reason for thinking that the remote causes of calculous affections obtain less commonly in females than in males. It is interesting, however, to note that this exemption from large calculi is afforded impartially to the different periods of life, and that, consequently, the residuary cases afford the same proportionate numbers of the different ages that the whole group itself did. In our analysis of 186 lithotomy operations in males, which we gave in this journal for January 8, 1859, 109 were under 10; 36 between 10 and 25; 8 between 25 and 45; 33 between 45 and 75. These relative members correspond as closely as can be expected with those given above, and show that the ages at which stone in the bladder is most frequent are pretty nearly the same in the two sexes.

FATALITY OF OPERATIONS FOR STONE IN THE FEMALE.—We are not aware that any statistical data have as yet been collected respecting the proportion of deaths which occur after

the removal of stone from the female bladder. The list before us gives two deaths to twenty-four cases, or one in twelve. This rate of mortality is, we fear, not at all above the true average. During the past six months (not included in our statistical period) another death has occurred in a woman operated on in one of the London Hospitals, and we are acquainted with the details of a fourth which happened in a provincial institution about six years ago, and just prior to our first publication of statistics. Regard being had to the very simple nature of the operation, a mortality rate of one in twelve must be considered as high. It is not, however, so much the nature of the operation itself as the antecedent state of the patient which influences the lithotomy death-rate both in males and females. In speaking of the causes of deaths in males, we had to point out that it was in the cases which had been long neglected,—in which the bladder, and, above all, the kidneys had become diseased,—that the deaths chiefly took place. The same remark applies to the series now before us. The two women who died were both adults, who had suffered from stone since childhood. They were both in worn down health, and had very large calculi. In one of them an autopsy proved that most extensive renal disease existed. As regards the operation, the death was undoubtedly a *post hoc*, but only in a very limited sense a *propter hoc*.

DIFFERENT MODES OF OPERATING.—In respect to the directions in which incisions should be made, and as to how dilatation should be conducted, very various indeed have been the procedures recommended for the removal of calculi from the female bladder. Lithotomy, properly so called, that is cutting into the bladder without dividing the meatus, has, however, been pretty much abandoned, and is now scarcely thought of in English practice. The only difference of opinion respecting the use of the bistouri, which now obtains, is, as to the direction, in which the meatus should be divided; some preferring, with Colot, (1727,) to cut directly upwards; others, with Chelius, to divide the urethra downwards into the vagina; and others with Dionis, (1716,) to make an oblique incision in each side. Sir B. Brodie has advocated the first of these, and Mr. Liston always adopted the last. A modification of the last was adopted by Mr. Hilton, in Guy's Hospital, in Case 3, which considering the large size of the stone and the bad health of the patient, was remarkable in its perfect success. Mr. Hilton adopts the plan of retaining a small catheter in the bladder, and of supporting the floor of the urethra,—which had been, as it were, let down by the lateral incisions—by means of sponge placed in the vagina. With regard to dilatation, it seems generally admitted, that it is best effected by a valve dilator, more or less closely resembling that bearing Mr. Weiss's name. Practically, we may classify operations for the removal of calculi in females under the heads of Lithectasy, or dilatation only, urethral Lithotomy, and Lithotripsy. The appended table shows the proportion of cases, in which each of these were respectively adopted in the series before us, and also indicates the results obtained as regards recovery and control over the bladder.

Nature of Operation.	Number of Cases.	Died.	Recovered	Had incontinence of Urine.
<i>Lithectasy</i> .—Extraction of the stone whole without incisions	7	None.	7	None.
<i>Lithotomy A</i> .—Extraction of the stone whole after limited incisions	3	None.	3	None.
<i>Lithotomy B</i> .—Extraction of the stone whole after free incisions	8	2	6	5
<i>Lithotripsy</i> .—The stone crushed, and either removed piecemeal at the time, or left to escape spontaneously	4	None.	4	None.

INCONTINENCE OF URINE AS A RESULT.—Dionis candidly informs us that three-fourths of the women on whom he operated for stone remained afterwards affected with incontinence of urine. This was in 1716, and before the practice of lithotripsy; his favourite operation being by double lateral incisions. He considered that incontinence could scarcely be avoided if the stone were large. Mr. Coulson (a), in allusion

to it, also writes, "This is the great objection to nearly all the methods adopted for the extraction of calculi from the female bladder. A considerable proportion of those operated on labour ever afterwards under the distressing accident of incontinence of urine." With these statements before us, the results of modern Hospital practice, as shown in the above list, are certainly good. Out of the twenty-two (b) patients who by different methods were rid of vesical concretions, two died, and of the remainder only six suffered afterwards from any degree of incontinence of urine. We might fairly claim to omit three of the other cases, inasmuch as in them unusual complications existed which altered the nature of the operation, and hindered the perfection of its result. In two of them hair-pins were present, and in the other the bladder had been injured by a fragment of impacted glass. Leaving these out of view, then, we have nineteen instances of the extraction of stone under ordinary circumstances, and of these only three suffered afterwards from incontinence. As explanatory of this satisfactory result, we must allege the greater frequency with which lithotripsy is now adopted, and the increased caution as to the practice of incisions. Excepting where the dimensions of the stone calculus are known to be unusually great, the Surgeon now never thinks of commencing his operation by incisions, as used formerly to be the case with many operators. He pursues the far better plan of ascertaining, in the first instance, whether the stone will not pass after moderate dilation of the passages, and on finding that it will not then proceeds either to crush or to make such limited notches in the urethra as are absolutely necessary. Instead of dividing ourselves into the advocates of dilatation and those of incisions respectively, we are now content to adapt special measures to each individual case, without laying down invariable rules. Every one admits that the moderate dilatation needed for the extraction of small stones is attended with almost no risk as to incontinence, and that in such cases incisions should never be thought of. After incisions to however small an extent, and after dilatation when immoderate in extent, it is equally generally admitted that the risk of this accident is considerable. Which of the two has the less of risk it is difficult to say positively, but probably the balance of evidence is somewhat to the advantage of incisions. But let us ask, why should either be resorted to? Why not in all cases of large stones in females employ the lithotripsy? There may be a few very exceptional cases in which the very large size of the stone and the worn-out health of the patient (as in case 17 in our list) render lithotripsy inadmissible, but even as regards them, the result of incision treatment is not encouraging, and they are besides very rare. In all others, however, in those for instance, in which the stone is neither too large nor too hard to be crushed, we can see no good reason whatever, why a patient should be subjected wilfully to the risks of incontinence, which undoubtedly attend both immoderate dilatation, and the employment of incisions, whilst we have such an instrument as the lithotrite. Lithotripsy in the female, is from obvious anatomical considerations simple and easy. As far as we are aware, its general results have been most satisfactory. As seen above in the cases before us, it was adopted four times, and in all the instances the patients recovered without any remaining incontinence.

PROPORTIONATE FREQUENCY OF STONE IN THE TWO SEXES.

—It has been generally believed, that about one female comes under surgical care for stone in the bladder to every twenty males. This at least, is the conclusion come to by Mr. Coulson, in his work on "Diseases of the Bladder," after citing data from various authorities upon the subject. In other words, about five per cent of our stone patients are females. This result appears to agree very closely with what has occurred in our English Hospitals during the period which our statistical reports comprise.

A FRENCH Surgeon exclaims—as English Surgeons have—that the Military Doctor is decidedly in the shade when honours are distributed. "The Egyptian expedition popularised the name of Desgenettes; and Napoleon honoured the names of Percy and Larrey; but is not this about all the honour which has been paid to the numerous brave representatives of our Profession?"

(b) Cases 8 and 20 are omitted from the above list for reasons which will be obvious to the reader.

SATURDAY, JULY 23.

GRIEVANCES OF THE EAST INDIAN MEDICAL SERVICE.

We understand that the Royal Army Medical Warrant, modified to meet the supposed requirements of the Indian Army, has reached India, and has been received by the Medical Officers of the Indian Service with considerable dissatisfaction, as it is considered that there is still too great a disparity between the advantages offered respectively to the Indian and English Medical Service in the recent arrangements. Indeed, the provisions of the new Warrant appear, in India, to tend so manifestly towards the depreciation of the Indian Medical Service, that we believe that the Supreme Government has suspended the promulgation of the document until a reference on the subject can be made to the home authorities.

We have, on previous occasions, alluded to the invidious distinctions drawn between the English and Indian Army Medical Services, to the disadvantage of the latter; and we had hoped that recent measures would have tended to reconcile the discrepancies which have hitherto existed. But we are sorry to find that notwithstanding considerable concessions, there is still much ground of dissatisfaction on the part of the Indian Medical service, in relation to the rank, emoluments, promotion, and retiring allowances, in all which respects the English Medical Service appears to be somewhat unduly favoured.

The grievances of which the Indian Medical Service still complain, may be comprehended under three heads; namely, relative rank, retiring allowances, and furlough allowances.

In the first place, the English Army Medical Officers still possess a superiority in point of rank over their Indian Medical brethren, inasmuch as no provision has been made to compensate for the exceedingly slow rate of promotion in the Indian service; the consequence is, that while an English Army Medical Officer obtains his Surgeon's commission and the relative rank of Major, on an average of ten years' service (the *present* average being, in consequence of the recent augmentations, only six years), the Indian Medical Officer does not attain a similar grade under an average of sixteen years' service. In the English Army, again, the number of Deputy-Inspectors-General is so great that almost all the active members of the service may look forward to the attainment of that grade in a reasonable period of time, with all its advantages of pay, rank, and retiring allowances, and even the number of the Inspectors-General is sufficiently great to render that grade also accessible within a moderate term of service. Such, however, is not the case in the Indian Army, for, in the Bengal Medical Service, consisting of about 450 Medical Officers, there will be, according to the New Warrant, only twelve Deputy-Inspectors-General of the Second Class, two Deputy-Inspectors-General of the First Class, and one Inspector-General: and the proportion in the

smaller Presidencies of Madras and Bombay must be even less, so that the chances of obtaining either of these positions is exceedingly small for each member of the service, until he has nearly completed the extreme term of service permitted by the Warrant.

With regard to promotion, the Assistant-Surgeons of both services are to be raised to the rank of Surgeons in the order of seniority, except in cases of distinguished service, where the rule may be dispensed with; but with this important difference, that whereas the English Army Officer, on his promotion, obtains substantive rank and pay, the Indian Medical Officer obtains brevet rank only. Such a distinction, as is here indicated, must be especially offensive to the members of the Indian Medical Department, when the circumstances of the case must frequently be in every respect identical.

In the second place, the retiring allowances of the two services exhibit the disparity in a still more striking light. A Surgeon in the English army is entitled to retire upon his pension, after twenty-five years' service, on full pay; the pension being calculated at seven-tenths of the pay of his rank at the time of retirement, provided he has served three years in that rank, or served in any rank ten years in the colonies, or five years with an army in the field; if he has not complied with either of these conditions, he is entitled only to the pension calculated at seven-tenths of the pay of the grade next below. If before the twenty-five years' service have expired, he is placed on half-pay by reduction of establishment, or is compelled to leave the service on account of wounds, or ill-health brought on in the discharge of his duties, he receives a pension according to his rank and services. Now the Indian Medical Officer is only entitled to claim his retiring pension after seventeen years' service, the amount of the pension being increased at first for every four, and subsequently for every three years of additional service. If incapacitated by wounds or ill health brought on in the discharge of his duties, and thus compelled to leave the service earlier, he receives from a fund bequeathed by Lord Clive for the benefit of officers unable to bear a tropical climate, the sum of £45 12s. 6d. per annum; if compelled to retire under three years' residence in India, and if beyond three years, and under seventeen, he receives the half-pay of his rank, calculated, if an Assistant-Surgeon, at £73 1s. per annum; or if a full Surgeon, £127 16s. 9d. per annum.

Thus it will be seen that the Indian Medical Officer labours, in every instance, under a considerable disadvantage, and is actually entitled, after an arduous service in the tropics, only to a lower rate of pension than the more fortunate English Medical Officer, who may have spent many years of his service in England, or at any rate in a European climate. If compelled to resign from ill health or wounds, the English Army Surgeon is liberally provided for, while his brother officer in the Indian army, if leaving under three years' service, is indebted to a private fund for even the small allowance he receives, and after that period of service is allowed only a very inadequate provision for his support.

Again, after a service of twenty-five years, the officers of both services are allowed to retire; but in the case of the English Medical Officer, if a Surgeon-Major, he receives £319 4s. per annum; if a Deputy-Inspector-General (which grade he almost invariably attains under that period) he receives £383 5s. per annum, and if an Inspector-General, he receives £574 14s. But the Indian Medical Officer, whatever may be his rank, after the same period of service, receives only £300 per annum, which is less than the lowest rate in the other case.

In the third place, the furlough allowances are greater in the case of the English than in that of the Indian Medical Officer, and if, from peculiarity of constitution, a Medical Officer of the English army is unable to endure a tropical climate, he is not necessarily required to resign all his pro-

spects in the service, but may still continue to serve at home or in one of the temperate colonies, until he has completed the full term required as a qualification for a pension. Such is not the case, however, with the Indian Medical Officer; for if a tropical climate disagree with him, he has no option but to retire; and not, like the English Army Surgeon, on a fair amount of pension, but if under three years' service, on the sum of £45 12s. 6d. per annum, accorded to him from Lord Clive's Fund; or beyond three years, he will obtain £73 1s. per annum if an Assistant-Surgeon, and £127 16s. 9d. if a full Surgeon.

While enjoying all these advantages of rank, retiring pension, and furlough allowances, the English Army Medical Officer is in no respect less favourably placed, as regards pay and allowances during his stay in India, than a member of the Indian service. Indeed he is, after the lapse of a short period of service, placed in a considerably better situation, in consequence of the greater rapidity of his promotion; for after fifteen years' service the Indian Medical Officer is probably still an Assistant-Surgeon, while the English Medical Officer has probably been a full Surgeon for *five years* previously.

From the above comparative statement, it is apparent that in every respect, whether as regards Promotion, relative Army Rank, Retiring Pensions, or Furlough Allowances, the Indian Medical Officer under the new warrant labours under very considerable disadvantages, while it may be fairly urged that in consideration of his term of service being entirely spent within the tropics, he is justly entitled at least to an equality, if not to some slight superiority, in the privileges and emoluments awarded to him. We believe that the facts embodied in the above statement have been communicated to the Supreme Council of India, and they will probably form the basis of a representation on the subject to the Secretary of State for India. We earnestly hope that that gentleman will inaugurate his recent appointment by a full measure of justice to our Indian Medical brethren, who certainly appear at present to have some just grounds of complaint.

THE WEEK.

THE College of Physicians of London lately deputed two of its Fellows to visit Hempstead, and to investigate, and report upon the condition of the tomb of Harvey. All that has been heretofore said respecting the disgracefully neglected condition of the remains of this great man, has been confirmed by the report of these gentlemen. The College has therefore resolved to take the matter in hand, and restore his tomb to a decent and respectable condition. The removal of his remains has been thought very inadvisable. It appears that Lady Eustace, the lineal descendant of Harvey, resides in the very parish, and enjoys the ancestral property handed down from Harvey. Perhaps the public notice which has been taken of these facts, may induce the heiress or heiresses, referred to in the following note of a *Times* correspondent, to take upon themselves the honour and credit of restoring their ancestor's tomb to a creditable condition:—"The family estate descended from the late Sir Eliab Harvey to his co-heiresses, who are Lady Eustace, Mrs. Cecil Fane, Mrs. John Drummond, Mr. Bramstone, and, I think, a fifth, whose name, however, I forget. These are all in affluent circumstances, and hold their ancestral property in or near Hempstead. I live in the immediate vicinity, and have repeatedly wished that the surviving members of the family would do themselves honour by honouring the tomb of their illustrious relative. This would, I think, be better than to remove his bones from their present uncared-for place of sepulture. Perhaps this suggestion may have its effect."

The Medical Register for 1859 has just been published, and is sold at the Office of the General Council of Medical Education and Registration, price seven shillings and sixpence. It forms a book of 335 pages, bound in red cloth, the names of those registered appearing to the number of about 15,000 in alphabetical order, with the date of registration, residence, and qualification, as prescribed by the Act. As a matter of course there is none of the information as to appointments and publications of those registered, which is the great characteristic of the Medical Directories. Dr. Hawkins offers some explanatory remarks, stating that even the extended time to the 1st of July has hardly sufficed for the due examination of evidence in the cases of many thousands of persons, most of whom preferred, as will be seen by the Register, not a single claim only, but each of them several distinct claims for Registration. He adds, "To want of time, therefore, and the urgent necessity for dispatch, should fairly be attributed many of the inaccuracies which may probably be found in this, the first copy of the Register, but which will be corrected in the editions of subsequent years." Many claims to registration of foreign qualification are deferred until answers are received to letters of inquiry addressed to various European and American Universities. Thus it will be some considerable time before the Register can afford the public or the Profession the means of distinguishing qualified from unqualified practitioners. Looking at the difficulties which had to be met, and which have been partially surmounted, we are not disposed to criticise this year's Register very closely, except as to the price charged for it, which is really exorbitant and unjustifiable. All other official publications of public departments are very properly sold cheap in order to secure their more extensive circulation. For example, the Eleventh Report of the Commissioners in Lunacy contains 138 pages, and includes many elaborate tables, yet it is sold for *ninepence*. The twelfth report has 56 pages, and is also full of tables, yet the price is only *fourpence*. At the same rate the price of the Medical Register should be *one shilling and tenpence*, instead of *seven shillings and sixpence*. If the Medical Council do not reduce the price to two shillings at the utmost, it will be necessary to submit the subject to the House of Commons.

The important matter referred to in our last week's number as under discussion at the College of Physicians of London, has, we hear, been adjourned for the present. The reason for the postponing of the discussion was, if we are rightly informed, that there were grounds for believing that, by the aid of the Medical Council, a union might be formed between the Colleges of Physicians and Surgeons, and a Board of Examiners established jointly from them, for the purpose of issuing Licences in Medicine and Surgery,—in fact, for forming what might be called the *beau idéal* of a General Practitioner. We are very glad to hear that such an alliance for the purpose indicated is likely to be brought about, and can only again repeat what we said last week on this subject:—

"We believe that a diploma granted by a joint Board of these two Colleges would grant the very honourable title which is required to make the Practitioner of this country what he ought to be. This is a scheme which we believe would give universal satisfaction. It recommends itself strongly to the common sense of every one; and we cannot doubt that if carried out, the Medical Council would take the matter in hand, and obtain an Act of Parliament which would legalise the licence before the world. Difficulties, of course, in the construction of such a joint Board must necessarily arise, but we cannot think them insuperable. There can, surely, be only a little straightforward determination required on the part of the two Colleges to bring to a happy conclusion such a

desirable object; and if we are not mistaken the path thereto has been already opened by an interchange of sentiments on the subject."

The Public Health Bill has been read a third time in the House of Commons, after a sharp discussion and a division, the numbers were 101 for the Bill, and 95 against it, the majority for the third reading being only 6. By this Bill the powers conferred by the Diseases Prevention Act, lately vested in the Privy Council, and a power of regulating vaccination, are made perpetual. An attempt was made to confer these powers for another year only, but the attempt was unsuccessful, and the Bill now goes to the Lords.

New arrangements have lately been made for conducting the business of the Army Medical Department. The Director-General is to be assisted by heads of three branches: Sanitary, Medical, and Statistical. Dr. Logan, Inspector-General, is the head of the Sanitary branch; Dr. Balfour, who has been promoted to the rank of Deputy-Inspector, is head of the Statistical branch; and Staff-Surgeon Dr. Mapleton, of the Medical Branch. Weekly meetings of this Board are to be held. The duties of each branch have been precisely defined, and we trust the plan will work well and benefit the service.

The view we have taken of the question, Who is a doctor? has, we are happy to find, been adopted by the Royal College of Physicians of London. In the midst of all the confusion and vacillation which is being exhibited in different quarters in dealing with Medical matters, we are pleased to see this College remain firm. We are informed that the College, last week, passed a resolution to the effect—that it will not officially recognise any Fellow or Licentiate of the College as a Doctor, who does not possess the title of Doctor of Medicine of some recognised University. We trust the Edinburgh College of Physicians may be induced to follow in such steps, and do an act of similar credit to itself. Though it have no legal power to prevent a Licentiate assuming the title of Doctor, it may, at all events, exercise its moral power to prevent such an abuse of terms. The Secretary of the Edinburgh College tells us:—"That this College does not profess to confer the title of Doctor, neither does it authorise its Licentiates to assume it." We, therefore, again repeat, that Englishmen take the licence solely that they may assume the title in question, and that they do assume the title. It is a mere subterfuge, unworthy the character of a College, with such facts before it, to satisfy itself with saying, "If Licentiates take the title, it is on their own responsibility." Why not boldly and honourably tackle the question as the London College has done, and either justify the act, or morally condemn it?

TESTIMONIAL TO JOHN SUTTON, Esq.—The members of the West Kent Medical Book Society, at their recent annual meeting, presented Mr. Sutton with a handsome library clock, as a mark of their esteem on the fiftieth anniversary of his Treasurership.

A HOSPITAL BUILT ON PURE RED TAPE PRINCIPLES.—A letter from Dr. Macdonell, the Deputy Inspector-General of Hospitals, dated Barbadoes, September 27, 1858, contained the following passages:—"I will this day recommend to the Commander of the Forces that the troops be kept for some time under canvass, purely that the St. James's Barracks is in the worst position possible. I may safely assert that if a premium had been offered to any person to select the worst spot he could in the neighbourhood of Port of Spain to erect a military barrack, the person who chose the ground for the present barrack would have been the successful candidate."

HER MAJESTY'S INDIAN FORCES.

EXAMINATION FOR APPOINTMENTS IN THE MEDICAL SERVICE.—JULY, 1859.

Written Examination.

NOTICE TO CANDIDATES.

In determining the relative merits of the candidates, so far as they can be ascertained from answers to printed questions, regard will be had both to the number of questions answered, and to the accuracy and completeness of each answer. But it is not required that all the questions should be answered by every candidate; for they are not only intended for ascertaining whether each candidate is qualified for an appointment, but for testing, both by their number and their difficulty, the relative abilities of the best candidates,—a design which is essential to a competitive examination, and which cannot be fulfilled unless some questions are asked to which only the best candidates can give good and complete answers.

NATURAL HISTORY, ETC.

Monday, July 11, 1859.—10 to 1 o'clock.

DR. HOOKER.

1. Describe the structure of the leaf of a flowering plant.
2. What are the principal earthy constituents and contents of animal and vegetable tissues?
3. How may the woods of coniferous plants be recognised? and what are the qualities that adapt them so well to economic purposes?
4. Upon what principle are plants increased by cuttings?
5. What are the chief esculents belonging to the natural orders umbelliferae, cruciferae, leguminosae, and amentaceae, and the peculiarities to which their nutritive qualities are due?
6. Give the botanical characters of the natural orders labiatae, valerianae, scrophularinae, campanulaceae, and melanthaceae.
7. What are the botanical characters of fungi, and how do they differ from other plants?
8. Describe the operation of making bread; and give the rationale of the several processes which the flour undergoes during its conversion to bread and to biscuit.
9. What are the races of man? how do they differ? and what relations can you indicate between the climate they inhabit and their food?
10. What parasitic animals inhabit man? Give their scientific names, the order, class, and habits of those you enumerate, together with the countries where each is most prevalent.
11. Describe the principal modifications of the hepatic organ in the animal kingdom.
12. What is coke? and what is its value, as compared with coal, for heating apartments by grates, stoves, and flues?
13. In what form is iron found in England? what is the process of smelting? and what are the differences between steel, cast iron, and soft iron?
14. What are the differences in quality between rain-water, well-water, and spring-water, and in their uses for drinking, washing, and other purposes?
15. Define, as precisely as you can, the terms aëration, gaseous, fluid, viscid, plastic, rigid, ductile, elastic, malleable, coriaceous, chartaceous, membranous.

SURGERY.

Monday, July 11, 1859.—2 to 5 o'clock.

MR. PAGET.

1. What diseases of the bladder and other urinary organs are likely to be consequent on long-continued stricture of the urethra? and what are the chief signs of each of them?
2. Describe the symptoms, and the attendant pathological conditions, of an ordinary case of suppurative disease of the hip-joint in a young person.
3. Suppose a wound with a penknife thrust straight through the middle of the cornea and penetrating a quarter of an inch; how would you treat such an injury, and each of its probable consequences?
4. Name the diseases that may be confounded with inguinal hernia (with or without strangulation), and state the diagnosis of each.

5. State the characters by which, without reference to the histories of cases, you would distinguish between the principal syphilitic diseases of the skin, and those of other than syphilitic origin.

6. Describe the condition of the uterus and adjacent parts in prolapsus uteri, and of any disease with which, during life, it may be confounded.

7. A girl, 20 years old, with habitually feeble health, received a slight blow on the front of her left ankle-joint, which gave her intense pain. From that time, during the 13 months that elapsed before she was seen by the writer, she had never been free from pain in the part, and had never been able to rest her foot on the ground. She described the pain as an aching in the ankle-joint, variable in intensity, but always present, often preventing sleep, often waking her, and sometimes accompanied by slight swelling at the ankle. At the end of the 13 months, the joint and the adjacent parts were neither swollen nor in any way misshapen: but pressure on any part of the joint was extremely painful; she could bear no movement of it; and the pain was increased by letting the foot hang down, or by pressing the sole. The pulse was always between 70 and 80; the hands and feet were habitually cold; and the general health was neither better nor worse than before the accident.

Write your opinion of the nature of this case, and of the best mode of treating it.

ANATOMY AND PHYSIOLOGY.

Tuesday, July 12, 1859.—10 to 1 o'clock.

MR. BUSK.

1. Describe the parts contained in the space circumscribed by four lines corresponding to the borders of the masseter muscle; proceeding from the surface inwards.

2. Describe the shoulder-joint,—noticing, in the order in which they are placed, the muscles, nerves, and blood-vessels in immediate relation with it.

3. Describe the urinary bladder, and its relations to the surrounding parts; the differences it presents in different degrees of fullness, and at different periods of life; the minute anatomy of its tissues; and point out the characters of the epithelium in the various parts of the urinary passages.

4. Describe what is meant by "reflex action" as applied to the nervous system; and give instances of the various phenomena attributed to its influence.

5. Describe the structure of the "ovum" in the bird and mammal; and the essential conditions of impregnation.

6. Arrange the secretions and excretions according to their reaction with test-paper.

MEDICINE.

Tuesday, July 12, 1859.—2 to 5 o'clock.

DR. PARKES.

1. Describe a paroxysm of acute mania. What diseases resemble mania? and how would you distinguish them?

Describe the treatment of mania.

2. What are the symptoms and chief causes of paralysis of the portio dura of the 7th pair?

3. What are the physical signs of obstructive and regurgitant disease of the aortic valve? What are the effects of such a disease on the heart, and on the system generally?

4. What are the causes, symptoms, and treatment of ascites in children and adults?

5. What are the symptoms, causes, and treatment of leucorrhœa?

6. What are the symptoms of poisoning by oxalic acid? and what is the mode of treatment? How would you test for oxalic acid in a complex fluid—the contents of the stomach, for example?

7. When mercury is given as a medicine, in what chemical form is it absorbed into the system? what are its effects while it remains in the body, and how and in what time is it eliminated?

What are the chief pharmacopœial preparations of mercury? and what are their respective doses?

8. In arranging a hospital, how many sick persons would you put in a room of the following dimensions: length 100 feet, breadth 30 feet, height 17 feet? State your reasons for assigning this number of persons to such a room, and explain what plans you would recommend in order to ventilate it.

REVIEWS.

A Treatise on Vital Causes. By JAMES NEWTON HEALE, M.D., F.R.C.S.E., Physician to the Hants County Hospital. Pp. 283. London, 1859.

PHILOSOPHERS in all ages have sought to discover the principle of life; but the result, in all cases, has been failure. The human mind, which has penetrated successfully into many of the operations of the material world, has developed the theory of planetary motion, has brought down lightning from the clouds, and has almost subjugated nature to its dominion, has nevertheless been baffled in its attempts to reveal the mysterious laws by which life is created and sustained, and by which the mental forces themselves are brought into operation. The little that man is permitted to know of his own nature and essence amounts to little more than that he originates from an organic molecule, animated by some living principle; that he grows and is maintained by taking into his substance matters derived from the surrounding world; and that, at the expiration of a certain period, the soul and body are disunited, and the corporeal framework is resolved into its gaseous, fluid, and earthy constituents. The investigation into the origin and source of life having been abandoned, by universal consent, efforts have nevertheless been made to unravel the nature of those powers by which the operations of life are supported, and the progress of decay retarded. The discoveries of chemistry and the newly-developed laws of voltaic electricity have given a fresh impulse to these inquiries as to the mechanism by which life is sustained, and theories, more or less plausible, have been devised to account for the phenomena.

Dr. Heale, in the work now before us, repudiates all claim to the discovery of any new truths as to the nature and origin of life, and he confines himself only to an investigation of the circumstances attending vital actions, and of the conditions on which those actions depend. According to him, life consists of a series of alternations of destruction and restoration; destruction ensuing from the processes of secretion and excretion, and restoration being effected by the introduction of air and alimentary matters into the system. "In order to live," says Dr. Heale, "it is necessary that portions of the body should continually die. Every vital act compels the consumption of some of the materials of which the body is composed: and, independently of that destruction which vitality requires and occasions, the body itself consists of ingredients so chemically constituted, as of their own nature, quite irrespectively of strictly vital causes, inevitably and rapidly ensure their own destruction, when exposed to that atmospheric temperature and to other dynamical influences, under which alone it would be possible for the body to exercise any vital functions. . . . But the destruction wrought by these combined causes demands to be compensated for by appropriate reconstruction, and by the due removal of the products of destruction. During life the restorative, as well as the destructive, processes are energetic in proportion to the degree of active vitality then prevailing, unless, indeed, the converse be the more correct way of stating the proposition, *i. e.*, that the vital action is the consequence and the measure of the restorative and destructive processes at any given time in operation, and the vital result the evidence of its energy."—Page 44.

Such being the premises laid down by Dr. Heale as the foundation of his treatise, he concludes his subject in the course of nine chapters, in which he successively traces the different physiological operations which are performed in the animal body. But while we readily admit that he has treated the various matters relating to the physiology of animal life with great skill, and no small amount of learning, yet we have failed to discover any striking novelty or originality in his views. He gives no details of experiments proving that he has detected any errors in the theories prepared by other writers, nor, indeed, does he show very clearly that any serious errors have been committed, at least by those who are considered as the modern guides in physiological science.

In the last chapter, headed "Views advocated in the foregoing Chapters, contrasted with prevalent doctrines," we certainly expected to find a somewhat broad line of demarcation drawn between the erroneous doctrines advocated by other physiologists and the more correct views advanced by

Dr. Heale himself; but although we have read the chapter several times over, we have been unable to convince ourselves either that the prevailing doctrines are very unsound, or that those of Dr. Heale will seriously contravene them. He speaks somewhat contemptuously of the "chemico-physiologists," and perhaps that class of writers deserve some censure for entertaining a somewhat too material view of the nature of life, and have pushed chemical theories rather too far; but our physiological authorities have generally kept such notions sufficiently in check to prevent their accomplishing any very extensive mischief; and some of the views attacked by Dr. Heale appear to us not to be of very great importance.

Notwithstanding these remarks on our part, Dr. Heale's book will repay perusal, as it contains much sound reasoning and an extensive acquaintance with physiological science. His leading idea seems to be that the blood is a living fluid, and that its waste and reparation are the necessary conditions of animal life.

The British and Foreign Medico-Chirurgical Review, or Quarterly Journal of Practical Medicine and Surgery. No. XLVII. July, 1859. London.

THE first article in the present number of this Review contains a very able critical summary of the views of Dr. Brown-Séquard on the Nervous System. It is well known that this distinguished physiologist has been for many years engaged in an extensive series of researches, which he has communicated to the Medical public through various channels, and the article in the *Medical Quarterly* presents a condensed report of these investigations, in which Dr. Brown-Séquard modifies, and sometimes corrects, the theories previously offered by Bell, Magendie, and other eminent authorities. This review is extended to a very considerable length; but considering the importance of the subject, the space is well bestowed, and the article will be read with general interest. The next paper is on a Copy of the Statistical Report of the Royal Navy for the year 1856, ordered by the House of Commons to be printed in 1858. These Reports were drawn up by Dr. Bryson, who still continues to superintend them. The results are exceedingly interesting, as exhibiting the influences which induce disease among our sailors; and it is remarked with regret that a great proportion of illness is due to syphilitic affections, which are said to be more prevalent in this country, especially in the garrison and great sea-port towns, than in any other part of the known world. Another article contains a series of abstracts from the 21st and 22nd volumes of the *Mémoires de l'Académie Impériale de Médecine*, which, as may be supposed, contain a great amount of interesting information. Mr. White Cooper's recent work on Wounds and Injuries of the Eye receives a fair and impartial notice in an able analytical review; and Frerichs' Clinical Treatise on Diseases of the Liver, of which only one volume has yet appeared, forms the subject of an article, in which an historical *resumé* is given of the pathology of this organ down to the period of Frerichs' researches. In a short review of some recent publications on the treatment of Insanity, a balanced opinion is given as to the relative propriety of consigning insane persons to an asylum, or of treating them singly at their own homes or in lodgings. The recent movement of the University of Oxford in the encouragement of general preliminary education, of natural science, and of Medicine in particular, together with the establishment of an efficient museum, give occasion for some eulogistic remarks upon the policy of this ancient seat of learning in relation to our Profession, and the reviewer anticipates that much benefit will result from this recognition of our claims, as an enlightened body, from so high a source. Dr. Brinton's work on Diseases of the Stomach is reviewed with the greatest favour, and it is no doubt entitled to this laudatory notice, as it is purely a scientific treatise, and wholly dissimilar to many books with the same title, having for their object merely to attract the public eye. An article on the works of John Hunter will be perused with great interest; the occasion of its appearance is of course the recent re-interment, in Westminster Abbey of the remains of the great anatomist. This article will be welcome at the present moment not only from the circumstance just adverted to, but from the fact that John Hunter is an author more talked of than read, owing to the peculiar infelicity of style which pervades his writings, and

renders their meaning sometimes very difficult to seize. It is, therefore, useful that analytical notices of his services to science should appear from time to time, in order to keep alive the veneration which is really due to his genius, obscured as it is by his unfortunate phraseology. We are inclined to agree with the reviewer, that his greatest contribution to science is the Hunterian Museum, which is indeed a book written in characters intelligible to all who will take the trouble to study it. "His tongue"—thus the article concludes—"was not fluent of speech, his pen was not that of a ready writer, but his hand, long skilled in dissection, became the readiest and the most faithful interpreter of his thoughts."—The *Bibliographical Record* contains notices of Corvisart on the Digestion of Nitrogenous Food by the Pancreas; of the Second Edition of Dr. Taylor on Poisons; of American translation of Malgaigne's Treatise on Fractures; of Dr. Barclay's and Dr. Hughes Bennett's Works on Clinical Medicine; and of other publications of more or less importance.—The original communications consist of the conclusion of Dr. Jago's paper on Entoptics; a paper by Dr. Murchison on the Simultaneous Existence in the Human System of two or more Diseases, supposed to originate from Specific Morbid Poisons—a paper drawn up with considerable ability; a contribution by Dr. Hyde Salter on some Points in the Clinical History of Asthma; and an article on the Effects of Rupture of the Internal and Middle Coats of Arteries by Dr. George Scott.—The usual half-yearly and quarterly Reports on Physiology, Materia Medica, Medicine, Surgery, and Midwifery, written respectively by Dr. Hermann Weber, Dr. Semple, Dr. Sieveking, Mr. Chatto, and Dr. Barnes conclude the number, which is equal to any of its predecessors in variety and interest.

PROGRESS OF MEDICAL SCIENCE.

Selections from Foreign Journals.

ON THE TREATMENT OF BURNS.

By Professor SCHUH.

Immediately after the burn has occurred we should pour over the parts, or bathe it with cold water; and when the part burned is but small,—e.g. part of a finger,—ease is derived by bringing it for a few seconds in the vicinity of the flame of a candle. In order not to lay bare the corium, the bladders that may have arisen should remain unopened during two days, or if they are very distended they should be opened with a needle. They should be opened also when their contents have become purulent. The exposed spots must be dressed with lint soaked in olive or almond oil, or spread with fresh butter or spermaceti, over which cold applications are to be laid. Cotton wool or wadding constitutes also an excellent protection against the action of the air. In superficial burns new skin forms under it, or the slight suppuration disappears, so that when the dry cotton falls off the skin is found healed beneath. The same result often follows the smearing superficially suppurating parts with the nitrate of silver, which gives rise to a crust, under which healing takes place. This means is not so effective, however, as some suppose, the mere keeping the surface of the wound clean having much to do with the healing. If the suppuration be not suppressed by its use, the surface is to be covered with charpie, cold water being continued to be applied if the inflammation is considerable, otherwise lukewarm water only. In great suppuration, a liniment of equal parts of olive oil and lime water is the best application. Under this simple treatment, or even by means of cold or tepid water may all burns of the first and second degree which are not very extensive be readily healed; and the popular remedies, flour, chalk, potatoes, etc., are only imperfect substitutes for cold applications. In the third degree, where there is considerable formation of eschar, the inflammation must be met by the raised position and applications of ice; and when the patient is young and strong a venesection is an excellent means of moderating the pain and inflammation. When there is a hard unyielding eschar, perhaps surrounding a limb, the excessive pain may be sometimes rapidly mitigated by free incisions being made in the eschar. When the line of separation has become formed the casting off the eschar is facili-

tated by warm, moist applications, or aromatic cataplasms, such as camomile—all swelling and heat having been, however, first removed. After the separation, the wound continues for some days, until the formation of abundant granulations, excessively sensitive; and we must choose applications that neither irritate or adhere so as to prevent their ready removal. Such are a soft ointment of yellow wax and olive oil, and linaments formed of cream or oil and yolk of egg. For the poorer classes a decoction of bran forms a good substitute. These applications may be continued for some time after the disappearance of the excessive sensibility; but if the surface of the sore is very large they will frequently render the granulations too flabby and the secretion too large. In such a case the linament of oil and lime-water and a solution of nitrate silver (2 to 6 gr. ad. 3) must be substituted. In excessive suppuration suitable ventilation, good diet, together with wine and quinine, must be provided, especially for the feebler patients, and when in these the suppuration takes on a bad character, the use of decoction of cinchona is of good service as a local application.—*Wien Wockenschrift*, 1859. No. 12.

ON PIGMENTARY RETINITIS.

By Dr. MOOREN.

Although the employment of the ophthalmoscope enables us to satisfactorily treat various morbid conditions, against which our art was formerly powerless, in many cases our therapeutical resources have not advanced at the same rate as our pathological knowledge. In proof of this may be adduced the peculiar affection of the retina, called by Graefe, after the name of the first patient in whom he had observed it, *morbus Arianius*, and by Donders, *retinitis pigmentosa*. Of this affection the author has met with seventeen instances. In all these the patients first complained of imperfect vision in bright light, and after a while of a sense of pressure and tension almost seeming to forcibly close the eyelids. Next symptoms of hemeralopia were observed in the evening, with subjective luminous sensations in the daytime. After sunset the patients could scarcely guide their steps amidst surrounding objects. Sometimes this state of things may continue in this way for years, but usually the disease augmenting advice is sought. The practitioner is immediately struck with the continual movement of the eyes, as if the patient sought by them to examine every surrounding object. It is a continuous, not a convulsive, movement as in nystagmus. Examination shows little external change, but a considerable concentric limitation of the field of vision. Internally a number of blackish spots are found on the retina, disposed circularly, parallel to the iris, sometimes in close contact, and sometimes separated by intervals. With the progress of the disease new masses of pigment are deposited towards the posterior pole of the globe, until the yellow spot itself becoming implicated, vision, which had become feebler and feebler, disappears. The papilla of the optic nerve, already atrophied and of a dirty white colour, is not only more or less effaced, but oftentimes covered in part with the pigment. The vessels of the retina, which at the commencement of the disease, are deformed, have now become more or less obliterated, and only appear as yellowish-white cords, in part concealed by the pigment. The other membranes of the eye become secondarily affected, especially the choroid. The posterior portion of the lens loses its transparency, forming the cataract known as the *C. poloris striata*. Pigmentary retinitis occurring in an individual suffering from myopia, or feebleness of vision, becomes the source of the greatest inconveniences. In the struggle of the accommodating powers of the eye, the affection formerly termed *staphyloma posticum karpæ*, or the *sclerotic-choroiditis* of Graefe, is developed.

According to Donders, the pigment first appears at the lateral part of the retina. The diminution of the field of vision seems, however, to precede the deposit, and in the author's opinion, arises from a derangement of nutrition, proceeding from the centre to the circumference, and affecting the optic nerve, as well as the retina. The ophthalmoscope exhibits, as one of the first symptoms, a progressive diminution of the calibre of the vessels. This obstacle to the circulation not only impairs nutrition, but leads to chronic inflammatory action, and as a consequence the transformation of the colouring matter of the blood into the pigment—the exudation of this being here a mere secondary phenomena. The origin of these pathological conditions must be referred to material

changes taking place in the vessels coming from the optic nerve. Graefe states that the disease is hereditary, and the author is aware of a family having four out of eight children the subjects of it, and another family in which three members were affected by it. Of the 17 cases he has met with, in 14 the patients inhabited marshy wet countries. The prognosis is always unfavourable; for although the disease is always slow in its progress, lasting from 20 to 30 years, it always terminates in complete blindness. At most, any treatment can only be palliative, and that only to a slight extent.—*Annales d'Oculistique*, tom. xli. pp. 21—31.

ON A NEW MODE OF DRESSING STUMPS AFTER AMPUTATION.

By M. LAUGIER.

This consists in the maintaining the edges in contact with each other, and the bringing them forward over the bones by the application of two plates of cork, half a centimetre in thickness beneath the roller surrounding the stump. The length and breadth of these plates must be such as to allow of their embracing the stump almost circularly, and to extend seven or eight centimetres beyond it. The free edge of the plates is digitated, each digit being pierced with a hole so as to admit ribbons or laces, by which, after the dressing is completed, the opposite digitations of the two plates are united two-and-two. Before applying the plates, circular pledgets of amadou are inserted beneath those parts of them which are opposite the deeper portion of the wound, so as to render compression at once gentle and efficacious. The plates so applied, retained by the bandage and attached at their ends by the laces, represent a continuance of the supporting pressure afforded by the hand of the assistant during the dressing; and for any dressing that may be required for the stump their extremities have only to be gently separated. They form a protection for the stump against all shocks, furnishing a solid and yet not a hard case, which allows of the patient making extensive movements without inducing pain. Under the use of this apparatus union of the deep-seated portions of the wound is promptly obtained, the soft parts are kept well over the bone, the inconveniences incident to the employment of strapping are avoided, and a degree of movement is allowed to the patient, which will greatly facilitate his treatment in the ambulances.—*Gazette Méd.* 1859, No. 19.

FRENCH STUDENTS AT OPERATIONS.—The same correspondent of the *Gazette des Hôpitaux* we quoted last week favourably contrasts the English with the French Medical Students in one point of view at least. Speaking of St. Bartholomew's, where he was most cordially received, he says that the Students (here, as at the other Hospitals, however, following the Surgeon in full dress, with gloves and canes) conducted themselves in the most orderly way, ranging themselves around the amphitheatre and leaving the area free to the operator and his assistants. "I was now able to convince myself of the truth of what Roux had so often told us, that every one remained in his place in the utmost order, without in any way obstructing the going or coming of those whose services were necessary to the Surgeon. At Paris, on the contrary, the area is always invaded, the pupils pressing around and elbowing the operator, so as to render his proceedings really difficult. Bitterly did Roux regret the absence of the excellent order of the English amphitheatres, and often expressed himself severely upon the subject, and sought to obtain it by means too burlesque to succeed. Sometimes he would soundly cuff those who pressed too closely upon him, or, taking a jug of water, he would interrupt an operation to deluge his invaders and compel them to resume their places. The fault does not always alone lie with the French Students, for the foreign visitors surpass them in this respect. But Roux combated an abuse alone, which he could not alone eradicate. But some Surgeons approved or even encouraged these invasions. One morning, just as M. Paul Dubois was about to perform the operation of turning, a bound into the area was heard behind him. Turning round and seeing three students crouching in front of the balustrade they had just climbed over, he said, 'Are you Frenchmen, gentlemen?' 'No, Sir,' replied the three culprits. 'I was sure of that,' replied the celebrated accoucheur, 'let this example serve for our own Students: I have never met with such zeal except among foreigners.'"

FOREIGN CORRESPONDENCE.

FRANCE.

PARIS, July 11, 1859.

IN recording, in one of our late communications, the operation of removal of the tongue close to its base, as performed by M. Chassaignac by the method "écrasement linéaire," and which terminated favourably, we find that we made a slight error regarding the interval allowed to elapse between the movements of the instrument. We then mentioned that it was two minutes; but an intelligent Medical friend who was present at the operation, and who carefully timed the process, watch in hand, informs us that only half-a-minute intervened. This correction we regard it of importance to make, seeing that the accuracy of the statement was confirmed by M. Chassaignac himself a few days ago, while lecturing on the subject, and while performing the same operation on the dead subject as well as on a living dog. This able and intelligent Surgeon stated, that in removing the tongue by the *écraseur*, the instrument, while constricting and dividing the tissues of the organ near its surface, might be worked more rapidly (twenty-five seconds or thirty being a sufficient interval between the movements), and that as the operation advanced, and important arteries and veins became involved, the interval between the notches of the instrument should be increased; but that half-a-minute would be found sufficient to guarantee perfect security against the loss of blood. It would appear that since its invention by M. Chassaignac, either the power of the instrument has been very much increased, or experience in its use has enabled him latterly to work it with a bolder hand, for we find that in two cases of amputation of the tongue performed by him some five years ago, as recorded in Guérin's work on Practical Surgery, the time he then required for the complete separation of the organ was in one case twenty-four hours, and in the other no less than forty-eight hours.

We have lately witnessed, in the service of M. Briquet, at the Hôpital "La Charité," the good effects of the application of "electricity by induction," or Faradisation, as it is now commonly called, in the treatment of lead colic. The views of M. Briquet on the pathology of the disease being somewhat new, and at variance with those hitherto entertained, a brief exposition of them, together with some remarks on the treatment which he adopts, may not be unacceptable to your readers. The following case, taken from our Medical "memo-randa," being one of several which we have lately seen brought to a successful termination, will serve as a suitable introduction to the remarks which form the sequel.

A house-painter, aged 34, was admitted a few days ago, labouring under all the symptoms of lead colic. It was his third attack. The first occurred as far back as 1843, and lasted eight days; the second took place three years ago, and he was then under treatment for a month. For some weeks prior to admission on the present occasion he suffered from uneasiness, with dull pains in the stomach and bowels. These pains assumed an acute character only two days before his entry into the hospital, and were accompanied with nausea and vomiting. At the visit, and when first seen by M. Briquet, he was writhing with pain and constantly changing his position in bed. During the paroxysms, between which the intervals were but short, he lay on his face with the knees drawn up. There was considerable hardness and retraction of the abdomen, rendering it impossible for him to assume the erect position. The pain was not confined to the abdomen, but extended to the muscles of the chest, as well as to the lower extremities,—in the latter he complained of a feeling of numbness. The pain was, however, most acute along the course of the rectus muscle of the left side, and over the hypogastric region on that side. The features were contracted, and expressive of great suffering, but there was neither fever nor constipation. After a very short interrogatory, M. Briquet, having no doubt as to the nature of the affection, proposed the immediate application of electricity. The pain being, as we have already stated, more severe over the left and lower portion of the abdomen, he selected this spot for the Faradisation, which was conducted as follows:—A wet sponge was attached to one of the wires of the apparatus, while a metallic brush was attached to the other. These, it may be re-

marked, are the appliances in use when the Faradisation is to be confined to the skin. The sponge was then placed in contact with the body at the superior portion of the left rectus muscle of the abdomen, while the metallic brush was passed over that part of it where the pain was most severe. The machine, which at first was but feeble, was made by degrees to attain its maximum of intensity, and as it increased in power the brush was passed more and more rapidly over the skin, until it produced a considerable amount of redness. The operation lasted precisely three minutes and a-half, at the end of which every symptom of colic had disappeared, and the patient who on admission was doubled up during the paroxysms, was now able to stand erect, and walk about the ward with the most perfect ease and altogether free from pain. Of course, it will occur to all who have had any experience in this peculiar affection, as it did to ourselves, that the mere removal of the local pain is not all that is indicated in its treatment; and hence that electricity applied, as described above, can only be viewed in the light of a palliative, other remedies being necessary for the elimination of the lead with which the system is supposed to be charged, and on the presence of which the colicky pains are presumed to depend. This is no doubt true; but the removal of one of the most painful and most alarming symptoms by such a simple and speedy process as that of Faradisation is, from the novelty of the measure by which it was accomplished, not unworthy of attention.

The question naturally occurs, Faradisation being merely palliative, and the exciting cause of the colics still in operation on the system, are these latter liable to return? On this point we can speak most decidedly as well from our own observation as from the statement of M. Briquet, whose experience in the treatment of this affection has been extensive. In only one of the cases which we have observed, was a second Faradisation necessary, the others having been completely cured of their colics by one "*seance*" only. M. Briquet's experience in somewhere about a hundred cases carefully observed by him, goes to prove that a relapse is by no means common, and if it does take place, it is generally after an interval of five or six hours; but that if the patient pass twenty-four hours without any return of the colicky pains, no further Faradisation will be necessary. Having got rid of the most urgent and the most alarming symptom of this disease by means of Faradisation, the medical, or rather the constitutional, treatment employed by M. Briquet with a view to the elimination of the lead, is extremely simple, as compared, at least, with the medication generally in use.

In the very Hospital where M. Briquet gives his valuable services, there originated some years ago a certain form of treatment for this disease, which became so famous that it passed, as it were, into a law, and was "par excellence" distinguished as "*le traitement de la Charité*,"—it consisted in the administration of emetics, purgatives, opiates, sudorifics, acidulated drinks, etc., all of which were to be given in strict conformity with rules and directions carefully laid down beforehand. This stereotyped plan of treatment M. Briquet has thought fit to abandon, substituting for it one which, if it has not yet attained to the same notoriety, is at least characterised by far greater simplicity. It is as follows,—the Faradisation terminated, a sulphur bath is ordered, which is repeated every second day during the patient's sojourn in the Hospital. He is ordered to drink every day about four pints of lemonade, to which are added from thirty to forty drops of dilute sulphuric acid. A gum potion is also prescribed, containing from thirty to forty grains of alum; and each night, or every alternate night, as the case may be, a pill is ordered containing one grain of the watery extract of opium. It will doubtless appear singular, seeing that obstinate constipation is so frequently a concomitant of this disease, that in this treatment there exists no element of a laxative nature. Purgatives he never prescribes, and rarely ever has recourse to an enema. In almost all cases he has remarked that the bowels begin to act spontaneously from one to three days after the Faradisation has accomplished the removal of the abdominal pains. The object of this treatment is simply the elimination of the toxic principle from the system; it exercises no influence whatever over the colics, nor is it intended to do so. Seeing that the first part of the treatment, namely, the removal of the pain of the abdomen by means of Faradisation is somewhat novel, it may not be amiss to inquire here on what pathological grounds it is founded. Among the earlier pathologists there existed little or no difference touching the seat of

this affection: all of them referred it to the digestive tube either in part, or throughout its entire extent. Of the cause and origin of the pain, however, there has been, and still continues much diversity of opinion; some maintaining that it originates in the contact of the particles of lead with the mucous lining of the digestive tube (a doctrine which, by the way, is no longer tenable, since the possibility of absorption of lead by the skin has been admitted); some think that the pains or colics result from an inflammatory condition of the mucous surface of the intestines, while others hold they are the result of the distension produced by accumulated fæces. Tanquerel, a man of no mean authority, traces the colics to functional disturbance of the great sympathetic nerve. Giacomini, of Padua, discarding all these theories, was the first to enunciate the views we now see acted on by M. Briquet, to wit that the pain in lead colic has its seat not in the digestive tube at all, but in the muscular parietes of the abdomen and the diaphragm. This same opinion we find hinted at, although not formally expressed, by Andral, Grisolle, and others whose attention has been specially directed to this malady. M. Briquet's reasons for his faith in the theory of Giacomini are founded on the following observations:—If, during the examination of a patient suffering under lead colic, moderate pressure be exercised over the abdomen, by means of the fingers, in such a manner as to affect only the skin and the subjacent muscles, without interfering with the more deeply-seated parts, acute pain will be produced identical in its character with that experienced during a paroxysm of colic. Again, if pressure be exerted over the abdominal muscles at points under which the intestinal canal does not run, as, for example, over the crest of the ilium, an acute pain will invariably be the result. These two reasons taken in connection with the extension of the pain to the muscles of the back and limbs, which is often observed in painters' colic, he considers conclusive as to the purely muscular character of the pains. The constipation, he believes, has no connection whatever with the abdominal pain, as it sometimes persists for days after the latter has been removed by Faradisation. The nausea and vomiting he regards also as purely sympathetic, depending, it may be, on the extreme sensibility of the muscles, and this opinion derives countenance from the fact that these symptoms invariably disappear when the hyperæsthesia has been removed. Neither Briquet, nor any other holding the same pathological views in reference to this disease, attempts to explain why, by preference, the abdominal muscles are those chiefly affected. In the present state of our knowledge this point involves some difficulty. Both Duchenne, of Boulogne, and M. Briquet, however, endeavour to account for it by adopting the hypothesis that there exists some elective affinity between the lead poison and this particular portion of the muscular system. In the treatment, by Faradisation, of the abdominal pains, or colics as they are erroneously designated, if M. Briquet's theory be a correct one, it may not be uninteresting here to inquire what is the *modus operandi* of the electricity. Does the Faradisation, by introducing into the system some peculiar modifying influence, restore the nervous energy to its normal condition, which the poison of the lead may have diminished or deranged, and so put an end to the hyperæsthesia or preternatural sensibility of the muscles? Evidently no; because, granting the pain to have its seat in the muscles, as maintained by Briquet, the end would be better and more speedily accomplished by the direct Faradisation of these muscles. Again, are we to attribute to the electricity so introduced into the skin, an anæsthetic or deadening influence on the nervous filaments which supply the muscles? To this M. Briquet also says, No. Faradisation, according to him, acts purely and simply as a revulsive in this affection, and is perhaps one of the most powerful agents of this class which we possess. For this reason, the skin is Faradised until it becomes red, and almost invariably as soon as the redness is produced the abdominal pains immediately disappear. Sometimes this operation requires great firmness on the part of the operator, and no small amount of endurance and courage on the part of the patient, the pain experienced being excessive, as evidenced by the cries and efforts of the patient to escape from the hands of the operator. The amount of suffering should, however, prove no objection to the process, as the Faradisation can be perfectly carried out while the patient is under the influence of chloroform, the peculiar action of which does not, we believe, interfere, in any way, with the curative effects of the electricity.

GENERAL CORRESPONDENCE.

THE EDINBURGH LICENCE AND FOREIGN DEGREES.

AN APPEAL TO THE JUSTICE OF THE MEDICAL COUNCIL.

[To the Editor of the Medical Times and Gazette.]

SIR,—Allow me to make an appeal through your columns to the sense of justice of the Medical Council in reference to my own position and that of many others in the Profession. The appeal shall be in the shape of a history, which cannot fail to interest many at the present moment, although it may be long. In the year 1838, when the University of London was established, the College of Physicians of London published and advertised extensively a statement of its power over the Profession, and (to quote its very words) "of the means which it possesses within itself of conferring the rank and privilege of Physicians on all those who, having had the advantage of a liberal education both general and professional can prove their qualifications by producing proper testimonials and submitting to adequate examinations." At the same time it announced its determination "to regard in the same light and address by the same designation all who had obtained its diploma whether they have graduated elsewhere or not." The regulations for the "degree" or "diploma" referred more especially at this time to the licence *intra urban*; but in 1846 Dr. Francis Hawkins, the Registrar of the College, wrote to inquirers, that the President and Elects required "exactly the same qualifications in those whom they examined for practising as Physicians in the country (*i.e.* as *extra urban* licentiates). The former regulations were annulled five or six years ago."

Well what was the result of this? Several leading physicians in London (as Dr. H. Davies, Dr. Alfred Taylor and others,) placed such entire confidence in the authorised and official asseverations of the College, that they underwent and passed the required examinations, and paid their money, in the full expectation that thereafter they would be entitled to write M.D. after their names, to be addressed as "Doctor," and to enjoy in short, all that belongs to "the rank and privileges of physicians." Up to the year 1845 no fewer than 220 persons in the country, took out the extra urban Licence of the College, with an equally confident expectation as to title, rank, and privileges. The fees paid by these 220 Licentiates in six years, amounted to little short of £4000, and as there is no stamp duty on the *extra urban* Licence (being granted under an Act of Parliament) the whole amount, deducting a trifle for expense of parchment and wax, was clear profit.

Well, Sir, I am one of those persons whom the College has induced for several years past, by its authorised and official advertisements to take out an *extra urban* licence. I had served for some years in the navy; I wished to retire and to take Physician's practise and fees, and having no Medical degree I took the at least strictly legal qualification advertised by the College. When there occurred a vacancy in the Medical staff of a public Medical charity established where I resided, I became a candidate for the appointment of Physician; I was opposed, not on the ground of professional unfitness, but because I was not a "Doctor," and had no right to write myself "M.D." I made a struggle to support my status; I appealed to the College for support and was repulsed; I appealed to the published advertisements of the College; to the Act of Parliament of 14 & 15 Henry VIII.; I was ignominiously defeated, and retired from the contest with my health so impaired by vexation, grief, and anxiety, that I was obliged to give up practice for awhile.

I then made another effort. Seeing I was certainly entitled by law to act as a Physician, I thought all that was needed in my case was to obtain the academic degree of M.D. from a University. A Scottish degree was at that time not less a foreign degree in England than a German or French. I therefore took out an Erlangen degree, which was easily granted to me *cave à honoris*, because I had already a legal connection (after one examination, mark, sir) with the venerable and aristocratic College of Physicians of London. I now enjoyed my title of Doctor in peace.

But to my renewed misery the Medical Act became the

law of the land. It could never have occurred to any one that existing rights would be confiscated, and I remained at ease in my mind while the bill was passing through Parliament. I find, however, that I was wholly in error. The Medical Council have refused to register my Erlangen degree, because it was not obtained after examination, and I am again in truth without the title, rank, or privileges of a Physician. Nay, I see from the correspondence which has passed between the same Dr. Francis Hawkins (whose representations misled me), and the Southampton graduates, that I am even deprived of what he and the College had assured me the possession of, the simple title in an honourable sense, of "Doctor."—Is this just?

But now let me come to the crowning injustice. A number of General Practitioners (all respectable men, doubtless) have obtained a licence from the College of Physicians of Edinburgh, in precisely the same way that I obtained my degree of M.D. from the University of Erlangen. They, it appears, are to be allowed to register their licence, and secure thereby the same privileges which I could only obtain by submitting to an examination, while I am not allowed to register that academic title, which merely empowers me to bear the title appropriate to my actual legal position. Can anything be more grossly unjust?

Many Physicians in England have been in the same difficulties as myself. Some have escaped from them by getting a degree from Aberdeen or St. Andrews; others have been forced to retreat altogether from the false position into which they have been led by the London College of Physicians, and abandon their rank. For my part I await in confidence an act of strict justice on the part of the Medical Council, namely,—1. That every Licentiate Physician without examination be placed in the same category with every Doctor of Medicine without examination. 2. That at least every "extra-Licentiate" be specially authorised to sign himself "M.D.," inasmuch as he holds legally the privileges and rank of an English Physician, in virtue of having passed the examinations required by statute. If the law of 1815 and 1858 provided for the customary rights of those practitioners who were in practice previously to 1815, although they had no legal qualification whatever, *a fortiori*, the customary rights of the extra-licentiates ought to be maintained, who have the strongest legal qualification possible.

One word more. If the Council do not deal out impartial justice to the Colleges of Physicians as well as to their victims, the Medical Act will be half a failure, and the Council will only fulfil half their functions. The duties of the Council are twofold; to regulate—1. Registration; 2. Medical Education. A distribution of licences to practice in return for money-payment, without first instituting an examination, can by no construction of the Medical Act, be the exclusive pecuniary privilege of the London and Edinburgh Colleges of Physicians; if it be a privilege at all, it must be common to all Boards; and, consequently, the Colleges of Surgeons might distribute Surgical diplomas to Apothecaries for money without examination, and the Society of Apothecaries might distribute licences to Surgeons for money without examination—which is absurd. The late distribution of licences, therefore, by the College of Physicians, under whatever pretence of expediency, is wholly illegal, and ought to be strictly dealt with by the Medical Council.

I am, &c.

AN "EXTRA-LICENTATE" AND
M.D. ERLANGEN.

July 11, 1859.

[The letter of our Correspondent certainly makes out a case of very great misfortune as regards himself, and we heartily sympathise with him. It is evident, however, that a College of Physicians must make rules for the many and not for the one. Our own opinion on this subject will be found expressed at length in last week's journal. As we then said,—If a College, twenty years ago, committed the irregularity of allowing its Members to take the title of Doctor, it surely does not follow that it ought to consecrate the error; nor, certainly, can men of this day, properly allow the *laches* of their predecessors, to go by unreformed. Here, then, is the simple position of the case: The College never had the right or power to allot the title of Doctor to its Licentiates. Nevertheless, it most improperly, some twenty years ago (in 1838) usurped the right. It now acknowledges its error, and has honourably

purged itself by a distinct declaration of its opinion. The regulation on this head, referred to by our Correspondent, was, however, as he himself hints, only in existence about twelve or eighteen months.—ED.]

LETTER FROM PROFESSOR LAYCOCK.

[To the Editor of the Medical Times and Gazette.]

SIR,—Objections having been raised against the correctness of my analysis of the lists of applicants for the honorary licence of the College of Physicians of Edinburgh, contained in a former letter, I beg to enclose you an amended, and as correct an analysis as I can make, up to the latest date. Nevertheless, my former analysis, in so far as it was adduced in support of my argument, was substantially correct. The only error was in the accidental omission of a numerous list, which had got misplaced. I am, &c.

Edinburgh, July 18, 1859.

T. LAYCOCK.

Residence and qualifications of applicants for the honorary licence of the Edinburgh College of Physicians up to July 12, inclusive:—

Graduates of Universities.				
Aberdeen and St. Andrew's	7			
Erlangen and Rostock	2			
Erlangen <i>cum</i> Lambeth	1			
College Qualifications.				
Members, Fellows, or Licentiates, of a Royal				
College of Surgeons	57			
Ditto with Licence in Midwifery	10			
Licentiates of Society of Apothecaries	42			
Ditto with Licence in Midwifery	1			
Licentiates of Glasgow Faculty	4			
Double Qualifications as Surgeons and Apothecaries	72			

Total 196

Graduates of Scottish Universities can claim the licence without examinations. None resident in Scotland have applied for it.

Considering the licence in midwifery as *nil*—of the non-graduated Practitioners (186), 114 had a single qualification, and 72 a double qualification.

Residence of Applicants.				
England	177			
Ireland	10			
Scotland	4			
Army and Mail Packets	5			

196

So few of the applicants were found ineligible by the Council of the College, that for all practical purposes the number of applicants for the licence may be considered as nearly equal to the number of recipients.

QUININE TREATMENT OF PERITONITIS.

LETTER FROM DR. HANDFIELD JONES.

[To the Editor of the Medical Times and Gazette.]

SIR,—In Number 470 of the *Medical Times and Gazette* there is a highly interesting report of the practice of a French Physician, M. Beau, at the Hôpital Cochin, in Paris. The reporter records his agreeable surprise at witnessing a genuine case of idiopathic peritonitis treated and cured by quinine, "to the entire exclusion of every other therapeutic measure." The amount administered is eight grains every eighth hour, the dose, however, being proportioned to the sensibility of the patient, and this medication is maintained several days. M. Beau premises an emetic and a purgative enema. Now, I suppose, the feelings of many, if not the majority of your readers, on the perusal of this account, will be one of very considerable incredulity. To attempt the cure of acute peritonitis by quinine sounds almost like pouring oil on a fire to put it out. To a great extent I must participate in this feeling, at least as regards dealing with English peritoneums. I am not, however, inclined *in toto* to reject the opinion of M. Beau, backed as it is by the testimony of your reporter, that quinine in such cases may actually exert a curative influence, the patient not recovering in spite of, but by the aid of the

medication. It is to be observed that it is not a matter of expectant treatment, but of a proceeding which surely must either do good or manifest harm; and it is not easy to suppose that anyone with ordinary powers of observation could deceive himself as to the result. At least, if M. Beau could, I cannot think that your intelligent reporter would be so misled.

So far, then, from casting the statements aside as absurd, I incline to believe that important instruction may be gained from it. The point which it seems to me to put in a strong light is the exceeding diversity of the process we call inflammation. Thus, two patients may both have the symptoms of acute peritonitis, so marked that there can be no question that similar anatomical changes have occurred in each, or that these differ only in the relative amounts of solid and liquid exudation; yet in these two cases the morbid process may be affected by remedies in the most different manner. In the one, leeching, vs., and mercurialisation may have the best effects; in the other, they may be highly pernicious, and such treatment as M. Beau's prove effectual for good.

I have put the cases, as it seems to me, most fair to do, considering our established experience on the one hand, and the testimony of high authority on the other. Moreover, in favour of the novel procedure, we have some evidence from our own Practitioners of an analogous kind. Asthenic pneumonia is clearly recognised as an affection differing from sthenic, not so much in anatomical change as in its reaction towards remedies. The same may be said of pleuritis, eczema, and of some eye diseases, not to mention other instances. I have recently seen inflammatory opacity of the cornea and iris in a male rapidly clear away under fifteen grains of quinine daily, after leeching, counter-irritation, and mercurialisation had been employed in vain. One essential point in the treatment of all inflammation is to appreciate at any given time whether or not any tonic can be borne. If the state of the affected part is such that the tonic does not irritate, and so aggravate the existing disorder of nutrition, there is every reason to expect it will prove highly beneficial. But it is often a delicate and difficult point to ascertain when a tonic may be given with advantage, and what kind, and in what dose. These are among the points of practice requiring the greatest acumen. All nerve toners are tissue irritants, speaking generally, and the object in view is to attain the one action without the other. If we can tone the naso-motor nerves of the inflamed part without irritating its tissue, we shall induce contraction of the arteries, diminution of the hyperæmia, and reduction of the temperature. This at least seems a matter of just inference from the results obtained by Bernard in experimenting on the sympathetic. When he galvanised the upper end of the divided nervous cord, the ear became pale and its temperature sank. Surely this state of comparative anæmia and coolness is what most Practitioners would consider highly favourable to the subsidence of inflammation in any part. One may not unfrequently witness therapeutical actions which resemble the foregoing closely. I know scarce anything more striking than to observe a highly injected, hot leg, exuding serum from all its cutaneous surface, become cool, comparatively pale, and covered with healthy cuticle under the use of *Liquor Arsenicalis*. Considering the known action of arsenic on nerves (as in neuralgia), it seems difficult to represent to one's mind the above remedial action in any other way than as a toning influence exerted upon the naso-motor nerves of the part. Could it be done, it would seem in all cases of inflammation the most desirable thing to act thus on the naso-motor nerves. But in sthenic inflammation it is impossible or undesirable, because the toning drug irritates the focus of the inflammation, and increases the mischief. This is what we witness in sthenic eczema, where arsenic produces injurious irritation. A certain passivity or tranquillity of the inflamed tissue is requisite to allow tonics their opportunity. As to the exudation, if it is poured out on a free cell-bearing surface, it escapes more or less readily; if it is enclosed in a parenchyma, or shut sac, it may either liquefy and return to the blood, or if it passes into the state of pus it usually runs the course of abscess. In any case, I cannot consider the afflux of an increased quantity of blood desirable as a means of promoting absorption of the effusion. Rather I conceive that the less the pressure on the capillary surface is from within, the more readily will fluidifying exudation be taken up. This seems certain from the results of vs. in promoting absorption. Practically, I believe,

we may recognise three conditions, or grades of inflammation. 1. That in which contrastimulant remedies are effectual in nullifying the exaggerated local attraction of blood to the part (sthenic inflammation). 2. That in which the process depends chiefly or entirely on naso-motor nerve paralysis, and is cured by nerve-toners, as quinine (asthenic inflammation). 3. That in which the process is of an intermediate character, and in which if left to itself it generally subsides spontaneously and favourably with little aid from art. The two latter grades are those which seem to predominate at the present day, marked instances of 1 are few and far between. When I consider my own experience and that recorded by others, it seems to me wholly impossible to regard inflammation as an uniform process, always and in all cases the same, and to be opposed in the same way. On the contrary, I believe it to be eminently "varium et mutabile," oftentimes veiling under an outshow of similarity most opposite tendencies. Its rational treatment appears to me to require to be regulated by an appreciation of this variability, of the tendencies in which the variations take place, and by a knowledge of means most suited to counteract each morbid tendency. I am sure the recognition of this view is of the greatest practical utility, and I cannot but think it has been strangely ignored by the opponents of vs. in the late controversy. I am, &c.

C. HANDFIELD JONES, M.B. Cantab. F.R.S.

THE GRAIN WEIGHT.

[To the Editor of the Medical Times and Gazette.]

SIR,—Is it advisable to alter the value of the grain weight in the new pharmacopœia? and if not, why not? The present grain, with its divisions and multiples, is the common weight of science, and especially of chemistry, with which pharmacy is inseparably connected. The avoirdupois pound with its divisions and multiples, is the common weight of trade, from which again pharmacy cannot be separated. Hence, it seems desirable that the avoirdupois pound should be adopted, and the present grain retained for pharmaceutical purposes, if they can be reconciled, and this, as the avoirdupois pound consists of 7000 grains, is not difficult. Indeed, the present weights of 10, 20, 30, 40, and 60 grains might be preserved; and the only additional weights required would be one of 100 grains, with the necessary multiples, to supersede the avoirdupois ounce, which is inadmissible, because it consists of grains and a fraction. Our connexion with physical science would be thus not only retained but strengthened, for the natural philosopher and scientific chemist use a decimal series of our present grain weights; but, by the proposed alteration of the grain, that connexion will be lost in the matter of weights, which is not a trifling matter, and, as I humbly think, without any adequate advantage, indeed, without any practical advantage at all. If this be so, and if the "enormous present inconvenience" which you have correctly stated will be the result of the change, be also taken into account, we shall have good reason for believing that the present grain will still be used to a great extent in pharmacy, in spite of all the colleges, and it will be very difficult to enforce the adoption of the new one. The Inspector of weights and measures may, indeed, banish the present series of weights from the shop of the druggist, as he does now the light weights from that of the grocer, but he cannot drive it from the private dispensaries of practitioners, many of whom will certainly still use it in their prescriptions; and as it is equally certain that the present grain will continue to be used by men of science, physicians and surgeons are not likely to discard it, at least in their physical and physiological experiments and researches. If Dr. Pavy continue his inquiry into the quantity of sugar formed in the animal system, or Dr. Smith into that of carbonic acid exhaled in respiration, (see Proceedings of the Royal Society, Nos. 32 and 34,) he will assuredly give the result in the present grains. It appears then that if the value of the grain be altered, we shall have in use two weights of the same name but of different values; and forming the commencement, or first term, of three series of weights—two used in pharmacy, and one in chemical physiology; surely this will be productive, not only as you state, of "much present inconvenience," but of great and lasting confusion.

July 12, 1859.

I am, &c. J. D.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JULY 5, 1859.

F. C. SKEE, ESQ. President, in the Chair.

A Paper by HENRY WILLIAM FULLER, M.D., Cantab. F.R.C.P.L., was read,

ON THE ADMINISTRATION OF BELLADONNA, AND ON CERTAIN CAUSES WHICH MODIFY ITS ACTION.

The Author was led to the inquiries which form the subject of this paper by observing the remarkable tolerance of belladonna exhibited by a child, a patient in St. George's Hospital, to whom he was administering it as a remedy for chorea. Fancying that the tolerance of the drug observed in the case in question might be attributable either to imperfection of the extract or to the modifying influence of the choreic spasms, he obtained other extracts of belladonna from Apothecaries' Hall, from Squire's, and from Jacob Bell's, in Oxford-street, and administered it, dissolved in water, to ten other choreic patients in the Hospital. In a twelfth case he administered atropine, obtained from Morson's, in Southampton-row. The result was in all cases the same—namely, extraordinary tolerance of the remedy, with a varying but not very satisfactory, effect as regards the subjugation of the choreic spasm—the tolerance of the drug being so great that one girl, aged ten, took seventy grains of the extract of belladonna daily, and a total amount of 1019 grains, or rather more than two ounces, in twenty-six days; whilst the child, aged fourteen, to whom the atropine was administered, took no less than thirty-seven grains in eighteen days. 1. The patients were all pale whilst taking the larger doses of the drug; and, in no instance, was there any feverish heat, or any rash or erythematous blush on the skin. 2. There was great weakness of the pulse in all the cases, and, in some, considerable quickness. 3. The urine was generally clear and acid, but scanty, and of high specific gravity, varying from 1024 to 1036. In three cases it frequently contained a copious deposit of crystallised lithic acid; and, in three other cases, it was usually loaded with lithates. In one case, for the space of a few hours, whilst the patient was under the toxic influence of the drug, it became ammoniacal almost as soon as voided. 4. In one case some difficulty was experienced in voiding the urine; but this was not observed in any other case. This difficulty passed off when the belladonna was omitted. 5. The tongue was always moist, but unusually red whilst the larger doses of belladonna were being taken, and the redness passed off when the drug was omitted. 6. The remedy did not, in any instance, exert a constipating effect; on the contrary, it appeared to prove aperient. An occasional purge was required only in three cases. 7. In five cases it ultimately gave rise to sickness and diarrhoea; but in every instance, save one, the choreic spasms had almost wholly ceased, and, in the exceptional case alluded to, had greatly subsided before those symptoms were produced. Whenever bowel symptoms occurred, mere omission of the medicine sufficed to cause their cessation. Did the existence of spasm counteract the influence of the drug and prevent their occurrence? 8. Dilatation of the pupils was very uncertain. In almost every instance the pupils were large before the administration of the medicine was commenced, and they invariably became dilated soon after a dose of the medicine was taken. The dilatation, however, was not to the degree observed when a solution of belladonna is dropped into the eye, and, in most of the cases, it passed off before another dose of the medicine was due. Its ordinary duration was about two hours and a half. In one case, excessive dilatation occurred for a few hours coincidently with the occurrence of sickness and purging. In two cases considerable dilatation was pretty constant; in one case it was seldom great. 9. In two instances only did the slightest indistinctness of vision occur. In one of these it was observed only on three occasions, and then only to a slight degree, and was not

accompanied by dryness of the throat, headache, or any impairment of the mental faculties; in the other, it took place more frequently, and, strange to say, was most complained of when the pupils were of their natural size, and were contracting freely under the stimulus of light. It was not attended by delirium, nor by any indication of the action of belladonna, and the administration of an additional quantity of the drug was almost invariably followed by its removal. 10. The drug did not, in any case, produce the slightest narcotic effect; and, in one case, it failed utterly as an anodyne. 11. In no instance was there any evidence of its accumulation in the system. 12. The tolerance of the drug was not in proportion to the severity of the choreic spasms. In Case 2, in which fourteen grains of the extract, daily, occasioned sickness and purging, the spasms were more severe than in Case 11, in which seventy grains were taken daily without disturbance of the stomach and bowels. 13. The curative effect of the drug was very uncertain. In seven cases its action appeared to be decidedly curative, but in two cases it failed to exercise the slightest control over the spasms; and in the other three cases, it is doubtful whether the improvement ought to be attributed to its action. Being desirous of ascertaining whether the tolerance of the drug was due to its decomposition in the stomach, or to its non-absorption, the author submitted to Dr. Marcet and Mr. Kesteven for examination some of the urine voided by a patient in Roseberry Ward, who at the time was taking sixty-four grains of the extract of belladonna daily. The former extracted atropine enough from three ounces of the urine to kill two white mice, and narcotise several others. The latter, from two ounces of the urine, obtained sufficient to produce dilatation of a cat's eye, to afford the beautiful filamentous crystals of atropine now laid before the Society, and to give the reactions which atropine yields with iodine water, tannic acid, chloride of gold and sulphuric acid, and bichromate of potash. The fæces also, on being analysed by Dr. Marcet, yielded abundance of atropine. Thus, then, up to this point, five facts appeared proved:—1st. That in cases of chorea extraordinarily large doses of belladonna and atropine are tolerated. 2nd. That the drug is absorbed into the blood, and therefore that the tolerance of it is not attributable to its non-absorption, nor to its being decomposed in the stomach. 3rd. That it does not accumulate in the blood, but passes out of the system with the urine and fæces, and probably with the other excretions. 4th. That it does not exercise that amount of control over the choreic spasms which would have been expected from the readiness with which it is tolerated by the system. 5th. That the tolerance of the remedy is not in proportion to the severity of the choreic symptoms. The question, therefore, arose as to whether the existence of chorea had any part in producing tolerance of the drug, or whether that tolerance may not have been due to some other circumstances? With the view of determining this point, the author administered the extract of belladonna to two convalescent children, whom he kept in the hospital for the purpose. To the one, aged seven, he ultimately gave thirteen grains of the extract daily, and to the other, aged ten, twenty-eight grains daily, without producing dryness of the tongue or fauces, or any symptom indicative of the action of belladonna beyond some temporary dilatation of the pupils. With the view of having the matter tested with children on a larger scale than is possible at St. George's Hospital, the author requested a friend who is attached to a large public institution for children to administer it cautiously in gradually increasing doses. Accordingly to eleven children, varying in age from three to six, one-eighth of a grain of the extract in solution was administered three times a day, and the dose was increased in the course of six days to half a grain thrice daily. To four other children, from eight to twelve years of age, a quarter of a grain of the extract was given, and the dose was increased in the course of six days up to one grain three times daily. These children were all in good health; the dose was gradually increased, and dilatation of the pupil was the only effect produced. To seven other children, between five and seven years of age, he began by giving one-third of a grain twice a day, and continued it for three days without perceiving any effect from its administration beyond slight dilatation of the pupil. He then prescribed two-thirds of a grain twice a day; but by mistake one grain and a third was given at a dose. The result of this large and sudden increase was that the children were all seized with sickness and vomiting; some of them had diarrhoea, and one of them had the violent

uncontrollable delirium characteristic of belladonna. Stimulants were at once administered, the belladonna was omitted, and on the following day the toxic effects of the drug had passed off, and the children were perfectly well. To adults the author administered the drug in pills and in solution, and he found that, however given, very small doses usually produce dryness of the tongue and fauces; that two grains daily will often excite vertigo and dizziness, and that it is not possible to establish a tolerance of the larger doses as in children. He was thus led to the conclusion that: 1st. The tolerance of belladonna is not attributable to the counteracting influence of choreic spasms, but is in some way connected with the age of the patient. 2ndly. That a much larger dose than is usually prescribed is well borne from the first by children of tender years. 3rdly. That in children, though not so in adults, a tolerance of the remedy is speedily established, so that the dose may be safely increased, rapidly, but gradually. 4thly. That special care should be taken in apportioning the dose to the age of the patient, and in not increasing the dose too rapidly, inasmuch as the usual toxic effects of the drug will be produced if too large a dose be given before a sufficient tolerance of the drug has been established. 5thly. That the milder toxic effects produced by the drug are of little importance, and subside without remedies as soon as the administration of the medicine is discontinued. 6thly. That adults cannot tolerate the doses of the drug which can be taken with impunity by children. The extraordinary difference in the tolerance of the drug observed at different periods of life, the author remarks, may be explicable by the medicine passing off with the urine, as also, probably, with the other excretions, more rapidly in childhood than in adult life; and he concludes his paper by the following suggestions: 1st. That inasmuch as belladonna is admitted to be productive of signal benefit in whooping-cough, even in the minute doses in which it has been hitherto administered, it is probable that a corresponding increase of benefit would result from the larger doses, which it is now proved may be safely prescribed under certain restrictions. 2ndly. That it deserves a trial in epilepsy, laryngismus, stridulus, and other spasmodic affections. 3rdly. That combining as it does antispasmodic, sedative, and slightly purgative properties, it may be productive of relief in certain cases of dyspepsia connected with infra-mammary pain, flatulency, and spasms in the abdomen. 4thly. That inasmuch as it exercises a remarkable power in controlling spermatorrhœa and incontinence of urine, and the experiments recorded in this paper prove that it is excreted with the urine, it is highly probable that its curative action in such cases may be due in great measure to its topical effect, and if so, that it might be applied locally with advantage.

OBSTETRICAL SOCIETY OF LONDON.

WEDNESDAY, JULY 6, 1859.

Dr. RIGBY, President, in the Chair.

ELEVEN Fellows were elected. Five gentlemen were also proposed as candidates for admission into the Society, who will be balloted for at the next meeting of the Fellows, on the 5th of October.

A paper by Dr. R. U. WEST was read on

A FATAL CASE OF PUERPERAL PERITONITIS, COMPLICATED WITH CYSTIC DISEASE OF THE LEFT OVARY.

The author was sent for on Friday, the 4th of March last, to see a patient who had been delivered, after an easy and rapid labour, three days previously, and who was said to be dangerously ill with inflammation. On his arrival, he found the woman suffering from distension, with excessive pain and tenderness, of the abdomen, so that percussion could not be borne; the tongue was white and slimy; pulse 140, very small and weak; there was headache, with delirium; and the countenance was wild and expressive of pain. It is also noted that there was milk in the breasts, that the lochia were checked, and that she had had a rigor the previous day. The following prognosis was made:—"She will die next Tues-

day." She was ordered a saline purgative, some calomel and opium, with fomentations, etc., and subsequently ammonia and wine. On Monday evening, March 7, she died. At the post-mortem examination, which was made on the following afternoon, a large ovarian cyst was found, the walls of which were black and gangrenous; the peritoneal coat of the small intestines was also seen to be in a similar condition. The paper concluded with a few general observations to show that this was a case of puerperal peritonitis, commencing about the third day after labour, and involving chiefly the peritoneal covering of an old-standing ovarian cyst. It was also remarked, that this is not the first case of fatal puerperal fever in which Dr. West has seen the milk continue in the breasts until death; and hence, though this is an exceptional occurrence, still we must not rely too much on it as constituting a favourable symptom. A discussion followed, in which Dr. Tanner, Mr. Ballard, and Dr. Routh took part. It was thought that, examining the facts as detailed, there was no evidence to prove that the case was not one of simple inflammation of an ovarian cyst instead of puerperal fever; while the prognosis which was given appeared somewhat extraordinary.

A paper by DRAPER MACKINDER, M.D., was read on

SUDDEN DEATH FROM OCCLUSION OF THE PULMONARY ARTERIES SEVENTEEN DAYS AFTER PARTURITION.

Two cases are detailed which have recently occurred in Dr. Mackinder's practice. In the first, the patient was thirty-two years of age, and had been delivered of her second child after a natural and easy labour. Seventeen days afterwards, while apparently in good health, she rose up convulsively, said she was choking, and died. On subsequently examining the body, a large, branching, fibrinous plug was found completely stopping up the right pulmonary artery and its immediate ramifications; while the entrance to the left pulmonary artery gave lodgment to a large and tolerably firm concretion. The heart was rather thin, and the lungs slightly congested; but there was no further trace of disease about the body. In the second instance, the patient had an easy labour, and, for a few days afterwards, all appeared to progress favourably, when she imprudently left her bed-room and exposed herself to cold. Shortly afterwards she was seized with difficulty of breathing, gasping, and cold clammy sweats, from which death relieved her in twenty minutes. Permission to make a post-mortem examination could not be obtained, and hence it could only be surmised that the fatal event was due to the plugging up of some important but smaller vessel than those found obliterated in the first example.

Dr. GRAILY HEWITT stated that an elaborate essay on sudden death during the puerperal state had been recently published in the "Memoirs of the Imperial Academy of Medicine of Paris," but the author of that essay had not thrown any considerable light on the interesting question of the cause of death under these circumstances. (The case of the Duchess de Nemours, who died from plugging of the pulmonary artery, would be in the recollection of the Fellows of the Society. From personal inspection of the clot, he was able to state that in that case the clot occupied the pulmonary artery and several of its ramifications, and was so firm that it could not have been formed subsequently to death. Respecting those cases in which sudden death during the puerperal state was connected with the presence of coagula in the pulmonary artery, he would hazard the following supposition as to the causes which lead to the coagulation:—"The blood was so altered in the pregnant woman as to favour coagulation, in the first place; and in the second place, the maintenance of the recumbent position usually rigidly enforced by the Medical attendant during several days after labour, favoured the stagnation of the blood in the heart and chest. It was not unreasonable to suppose that these circumstances had much to do with the occurrence of this fatal accident.

Dr. PRIESTLEY recommended that in all cases of sudden death from occlusion of the pulmonary artery, an attempt should be made not only to give an accurate account of the thoracic organs, but also of the condition of the uterus and appendages, more especially of the bloodvessels and lymphatics. The researches of Virchow on this subject had conclusively shown the connexion between emboli formed in the uterine veins, and plugs found in pulmonary arteries the

value of reports on such cases would therefore be greatly enhanced if the investigation were carried further than the immediate seat of obstruction. He thought it not improbable that in chloroanæmic conditions of the system, when there is an increase of fibrin in the blood, a very small amount of acrid material generated in or near the uterus, and added to the blood circulating in the vessels, might cause deposition of the fibrin, and consequent occlusion of the vessels.

A paper by W. O. PRIESTLEY, M.D. etc. was read on

A CASE OF LABOUR COMPLICATED WITH FIBROUS TUMOUR OF THE UTERUS;

DELIVERY BY LONG FORCEPS, ETC.

The author stated that in 1858 he had been consulted by the wife of a professional friend, who was suffering from menorrhagia, and to whom he recommended a plan of general treatment in the first instance; but no improvement taking place, the cervix uteri was dilated by sponge-tents, and a cluster of vesicular polypi removed. No fibrous tumour or large polypus existed at the time, but an irregular nodule, about the size of a hazel-nut, projected into the uterine cavity at the junction of the cervix with the body of the organ. The lady soon afterwards became pregnant; and when labour supervened, the first stage was obstructed by the presence of a flattened mass in the lower segment of the uterus, which turned out to be a fibrous tumour, four inches in diameter, and more than an inch in thickness, situated exactly where the fibrous nodule had been discovered before pregnancy. The effect on the labour was to prevent the head descending on the os uteri, the entire uterus, with its contents, sinking low in the pelvis, and becoming impacted there. Turning was considered impracticable, but the dilatable condition of the os uteri allowed the use of the long forceps, and delivery was thus effected without injury to the mother—a living child being produced. Subsequently, during the involution of the uterus, the tumour was enucleated, and hung out of the uterus into the vagina. During this process, the constitutional irritation and local pain were so great that it was found advisable to remove the tumour. This was done by the *écraseur* on the fourteenth day after delivery, and so much bleeding followed as to necessitate the use of the plug. Ultimately, the patient made a favourable recovery. The author believed the hæmorrhage might have been less, after the removal of the tumour, had the *écraseur* been used less rapidly.

Papers by Dr. CLAY were read, on

A CASE OF SPONTANEOUS RUPTURE OF AN OVARIAN SAC EXISTING WITH PREGNANCY, AND ITS SUCCESSFUL TERMINATION,

AND

A CASE OF SUPPOSED ABSENCE OF UTERUS AND OVARIES.

The titles of these papers sufficiently indicate their nature. With regard to the latter,

Dr. RIGBY stated that he had met, in the course of his life, with several cases of deficient or absent uterus. He had described two or three in the early numbers of the *Medical Times*, as illustrations of one form of amenorrhœa, the patients never having menstruated. Some of these cases were accompanied with a defective or closed state of the vagina; in others, there was merely a short vaginal canal, at the upper extremity of which a small nodular body pointed out the presence of a rudimentary uterus; in others, no trace of a uterus could be detected. In one case of a married woman, where menstruation was regular, the vaginal walls were merely adherent throughout their whole length. He fixed a globular sponge tent firmly between the labia by means of a T-bandage, and having produced a slight separation, was enabled to continue it up to the extremity of the canal, where a healthy uterus was found.

In answer to a question from Dr. Tanner, as to what had been the success of operations in such cases, he (Dr. Rigby) regretted that in the case just alluded to the patient returned immediately into the country, and he had heard nothing more of her. He remembered an extremely interesting case, occurring some years ago, at St. Bartholomew's Hospital. A young girl, seventeen years of age, had well-marked molimina menstrualis, but no catamenial discharge appeared. As these periodical attacks became more and more severe, with

great constitutional disturbance, she came into the Hospital. A congenital abnormal state of parts was found. The vagina formed an irregular bifid canal, without any os or cervix uteri. On further examination, it was found that the posterior wall of the bladder, at its lower half, was wanting, so that the vagina and bladder formed one cavity, divided at its upper portion by a crescentic septum. Behind the vagina, a hard, globular mass could be felt, which was punctured so as to permit of the escape of some retained menstrual fluid. Unfortunately, the puncture healed, and the patient left the Hospital.

A paper by EDWARD RIGBY, M.D. was read, on

TWO CASES OF CRANIAL BLOOD-SWELLING, WITH REMARKS ON

THE NATURE OF THESE TUMOURS.

After relating the histories of two examples, the author proceeds to show that these cases are not unfrequently mistaken for hernia cerebri, an exceedingly rare and dangerous malformation, and which never occurs on the parietal bone, but always over a fontanelle or a suture. On opening these cranial blood-swelling, they are found filled with dark, semi-fluid blood, beneath which the bone is healthy. The collection of blood is usually beneath the scalp and tendinous aponeurosis of the occipito-frontalis muscle, the bone being covered by its pericranium. Sometimes, though more rarely, the pericranium itself is elevated by the collection of sanguineous fluid; and besides these two forms, other modifications of cranial blood-swelling have been described, but if they really do occur, they are of exceeding rarity. Great misapprehension has been entertained by several authors respecting the progress of these tumours. Thus, it has been stated that much constitutional disturbance would be set up if this accumulation of blood were allowed to remain; that it would become putrid; that fever would result; that there would be danger of ulceration, sloughing, etc. Hence it has been recommended to open these swellings, and evacuate their contents at an early period, before these changes could occur. But the success of these modes of treatment has been anything but encouraging, and hence Dr. Rigby advises that the practice of Professor Nægelé should be followed. This consists literally in doing nothing. As long as the infant remains healthy, the effusion will gradually be absorbed, so that by the time the child is a month old the tumour will have entirely disappeared.

SPONTANEOUS GENERATION THEORIES STILL HOLD THEIR GROUND IN PARIS.—M. Doyère has invented an apparatus which by the aid of sulphuric acid will purge the air of all organised germs. If in such air organic germs arise, then, he says, spontaneous generation is a fact, but if not, still this does not prove that spontaneous generation is a chimera; "it may perhaps only prove, that organic matter in order to become organised and take life spontaneously must not previously undergo this cooking process."

TRIAL FOR THE ADMINISTRATION OF STRYCHNIA IN PLACE OF SANTONINE.—This trial has excited great attention at Limbourg, and indeed over the whole of Belgium. A Dr. Simons, of Alken, was called to a child suffering from worms, and administered some santonine, which he, being also a *pharmacien*, kept in his own dispensatory. The child, 7 years old, died in a few hours after the first powder, amidst horrible convulsions. Dr. Simons, Degheest, (a druggist at Brussels who had supplied medicines to Dr. Simons,) and the druggist's shopman, were charged before the tribunal with the child's death. Analysis showed that the bottle sent a few days before by Degheest to Simons contained one part of santonine, and five parts of strychnia. Degheest denied that it left his shop in that state, and Simons maintained that he had received it just as he used it; and that country practitioners had neither time, skill, or means to chemically examine the preparations sent by their druggists as the law orders them to do. Simons received a high character for great care, and his dispensatory was in most excellent order; while Degheest's shop was in a state of disgraceful confusion. The court sentenced Degheest to a month's imprisonment, 200 francs fine, and half the expenses; his shopman to a fortnight's imprisonment, 100 francs fine, and a fourth of the expenses; and Simons to 50 francs fine, and a quarter of the expenses. The two latter have appealed.

PARLIAMENTARY INTELLIGENCE.

PUBLIC HEALTH BILL.

Mr. T. DUNCOMBE inquired whether it was intended to proceed with this Bill without giving an opportunity of discussing it, the Bill had only been introduced on the 4th of July, and stood for a third reading this evening?

Sir G. LEWIS said the reason why the Bill had been pressed on was, he believed, because the commission would expire on the 1st of August, and if it was to be renewed the Bill must be passed at once.

Mr. T. DUNCOMBE thought a continuance Bill for one year would be sufficient; so that the subject might be discussed next year.

THE INDIAN MEDALS.—ARMY MEDICAL OFFICERS.

Captain L. VERNON asked the Secretary of State for War whether he would recommend that the clause No. 12 of the Commissariat Warrant be extended to the Medical Officers' Army Warrant, whereby a Medical officer after twenty years' meritorious service, if pronounced by a Medical Board as permanently unfit for service, either mentally or physically, may be allowed to be placed on the permanent retired list. He also wished to ask the Secretary for War when the medals would be issued which it was understood would be granted for the achievements of the army in India.

Mr. S. HERBERT replied that as to the medals, as soon as it was decided for what operations they should be granted, instructions were sent out to Lord Clyde to furnish lists, which had not yet been received. With regard to the commissariat and Medical officers, he believed that both services had been treated according to a just appreciation of their services, and he was not prepared to say that the particular rewards given to one should be extended to the other.

THE PUBLIC HEALTH BILL

passed its third reading on the 19th inst. Endeavours have been made to raise an opposition to it on grounds which are destitute of all truth. It is represented as being a Bill for making vaccination compulsory and saddling parishes with the expense. It neither does, nor can do, either. The Act of 1853 (16 & 17 Vic. c. 100) did both. This Bill is to authorise the Privy Council to give such directions to public vaccinators appointed under that Act as shall insure that the vaccination shall not be paid for unless it is properly performed. It is compulsory only to that extent, and exclusively in favour of those who are already bound to submit to compulsory vaccination, and those who are already bound to pay for its being performed. The Bill will authorise the Privy Council to have inquiries and reports made on the causes of disease, where the percentage of deaths is above the proper average, or other reasons for investigation exist; but neither the Privy Council nor any other authority will be empowered to make any order, however desirable, consequent on any such report. What will be obtained will be publicity, and only that moral compulsion to do something to mitigate local or other evils which publicity may impose.

On the 19th inst. Mr. Whiteside obtained leave to bring in a Bill to amend the Medical Acts 21 & 22 Vic. c. 9, and 22 Vic. c. 21.

THE RIVER THAMES.

Sir G. C. LEWIS, in moving for leave to bring in a Bill to extend the powers of the Conservators of the River Thames, said the object was one which would be approved by the House,—viz. to assist in the purification of the river Thames. He was afraid, however, it would be of a very limited extent. The Conservators had represented to him that certain of their powers were deficient with respect to preventing the conveyance of impurities into the river, and he proposed to bring in a short Bill to supply that defect.

The motion was agreed to.

In reply to Sir J. PAXTON, Mr. S. HERBERT said that Netley Hospital was being proceeded with, and was in an advanced stage. He had originally been opposed to the selection of this site, and to the arrangement of the Hospital, but the opinion of the scientific men who were consulted having been adverse to his, he had withdrawn his opposition, and he should be very glad if it turned out that he was wrong and they were right.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS.—At the Comitia Majora, held on Friday, the 15th inst. Dr. John Langdon Haydon Down, of Earlswood, Reigate, was admitted a Licentiate of the College under the recent temporary Bye Laws.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners on the 15th inst:—

ADAMS, MATTHEW A., Margate.
 AGAR, FREDERICK, Royal Navy.
 ARMINSON, JOHN, Preston, Lancashire.
 ANNANDALE, THOMAS, Newcastle-on-Tyne.
 BARRETT, ALFRED E., Eton, Bucks.
 BARROW, EDWARD S., Demerara.
 BRACEY, CHARLES J., Birmingham.
 CATT, ALFRED, Brighton.
 DAVIS, GEORGE H., London.
 DAVIES, JOHN S., Oswestry.
 FRENCH, JOHN G., Ballygar, county of Galway.
 GLASIER, GEORGE W., Lincoln.
 HARRIS, WILLIAM J., Worthing.
 HODGSON, JAMES B., Preston.
 HOLMAN, THOMAS, East Hothley, Sussex.
 LOVEGROVE, CHARLES, Maidenhead.
 MENZIES, JAMES I., Upper Stamford-street.
 REED, SAMUEL C. Hemel Hempstead.
 STEELE, JAMES, Lancaster.
 STOTHARD, JOHN M., Dublin.
 TAYLER, HERBERT, Lywardreath, Cornwall.
 WITHERS, FREDERICK J., Tetbury.

Also on the 18th inst. :—

BAMFIELD, SAMUEL, Falmouth.
 BARNES, WILLIAM E. G., Newbury, Berkshire.
 BLENKINSOP, WILLIAM H. East Indies.
 BOLT, ROBERT A., Looe, Cornwall.
 CHARLTON, EGBERT, Tunbridge.
 COCKS, BENJAMIN, Tamworth.
 COOPER, GEORGE F., Caversham, Reading.
 DAVEY, EDWARD M., Sawston, Cambridgeshire.
 FOX, CHARLES H., Brislington, Somerset.
 FULLER, WILLIAM F., Bridgewater, Somerset.
 HAMMOND, CHARLES, Southampton.
 HIDE, JOHN, Brighton.
 HILL, JOHN D., Brentford.
 ISTANCE, RICHARD, Carmarthen.
 MEAD, HENRY T. H., Canterbury.
 M'GOWAN, SAMUEL A., Belfast.
 MOORE, DAVID, Royal Navy.
 PEMBREY, THOMAS, Overton, Flintshire.
 ROWBOTHAM, WILLIAM, Woolwich.
 SAMON, WILLIAM T., Canada West.
 SMITH, SETH, West Deeping, Lincolnshire.
 THOMPSON, ABRAHAM, Gosforth, Cumberland.
 WEBSTER, FREDERICK R. St. Albans.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, July 14, 1859 :—

LEE, JOHN, Ashbourne, Derbyshire.
 MANN, DAVID, New Wortley, Leeds.
 MARTIN, TIMOTHY HENRY, Merthyr Tydyl.
 MORETON, THOMAS, Marton-hall, Cheshire.
 TROTTER, CHARLES HARDY, Coleford, Gloucestershire.

The following gentlemen also, on the same day, passed their first examination :—

BAKER, THOMAS YOUNG, Hargrave, Northamptonshire.
 BURRELL, LIONELL, Westley, Bury St. Edmunds.
 CANN, FRANCIS MARK, Trinity-terrace, Boro'.
 DAWSON, WILLIAM HENRY, Exeter.
 FIRTH, J. T. FORBES, Cherry-garden-street, Bermondsey.
 GEORGE, AMBROZE BROOKE, Liverpool-road Infirmary.
 GIMSON, WILLIAM GIMSON, Walton, Leicestershire.
 MARSH, T. HENRY, Upton-on-Severn, Worcestershire.

MORRIS, ISAAC, The Cliffe, Lewes, Sussex.
 ORTON, GEORGE, Belle Vue, Coleorton.
 PARK, WILLIAM, Ulverstone, Lancashire.
 WOODMAN, JOHN, Bedford-circus, Exeter.

APPOINTMENT.

ROYAL COLLEGE OF SURGEONS.—At a meeting of the Council of the College on the 14th inst., Mr. James Moncrieff Arnott, F.R.S., was elected President; and Messrs. John Flint South, of St. Thomas's Hospital, and Cæsar Henry Hawkins, F.R.S., of St. George's Hospital, were elected Vice-Presidents of the College for the ensuing year. This is the second occasion in which these honours have been respectively conferred on the gentlemen in question. On the same occasion, Mr. John Hilton, F.R.S., Surgeon to Guy's Hospital, was elected the Professor of Surgery, in the vacancy occasioned by the resignation of Professor Hewett; and Mr. William Scovell Saovory, F.R.S., of St. Bartholomew's Hospital, was elected Professor of Comparative Anatomy and Physiology in the vacancy occasioned by the resignation of Professor Busk.

DEATHS.

DAVEY.—On the 9th inst. at Nice, Appes-Maritimes, Robert Davey, M.R.C.S.L., formerly of Keppel-street, Russell-square.

EDWARDS.—On the 29th May last, at Wolverhampton George Edwards, F.R.C.S., aged 51.

HARMER.—On the 5th inst. at Wrentham, Suffolk, Alfred Harmer, M.R.C.S., aged 45.

MANTELL.—On the 12th inst. at his residence, Green-park, Bath, George Mantell, M.D., late of Faringdon, Berks, aged 76.

PRING.—“Last week, died of paralysis, at the age of 70, Dr. Daniel Pring, a voluminous writer on physiology and the philosophy of life. He was born in Taunton, but settled in Bath as a Physician, where he remained for thirty years, one of its most distinguished literary and scientific illustrations. In 1813 he published his first work on the Absorbents. In the same year he gained the Jackson prize, for his ‘View of the Relations of the Nervous System in Health and Disease.’ Six years afterwards he produced his ‘General Medications,’ which relate to the laws of organic life—considered his principal contribution to Medical philosophy. Many other works flowed from his pen; and he has left behind him several ready for the press, but with an instruction to his executors that they are all to be put in the fire.”—*Athenæum*.

SINCLAIR.—On the 16th inst. at York-street, Portman-square, Jeffery Amherst Sinclair, late member of the Medical Board, Bombay.

WISE.—In June last, at Norton, Thomas Wise, M.R.C.S., aged 39.

THE Charing Cross Hospital, on the 19th instant, held its thirty-eighth annual meeting.

ONE of the crowned heads of Europe, the Queen of Portugal, died on the 16th instant from sore-throat.

THE Soirée of the Royal College of Physicians of London is fixed to come off on the 3rd August.

THE Statue of Jenner, erected by national subscription, has just been exposed to view before the Louvre, facing the Pont des Arts. It is a work due to the chisel of M. Paul.

PLEURITIC FRICTION SOUNDS.—M. Trousseau, at the Hospital Medical Society of Paris, has called in question the existence of such sounds! After this, well may a man ask: What is a fact in Medicine?

PATHOLOGY OF THYMUS GLAND.—According to M. Friedleben:—1. The thymus gland, neither in its normal nor in its hypertrophied state, suffers any turgescence except after food; there is no such thing as a hyperæmia and periodical turgescence. 2. It never interferes with respiration or circulation either in its normal or in its hypertrophied state; nor can it compress the respiratory nerves, nor does it in either of these states interfere with the cerebral circulation, or the innervation of the muscles of the glottis. There is no such thing as a thymic asthma.

THE IRISH COURT.—The following appointments have been made by the Lord-Lieutenant:—Physicians in Ordinary, Dr. John Banks, Dr. John Hughes; Surgeon to Household, James S. Hughes. M.D.; Surgeon in Ordinary, G. W. Hatchell, M.D.

L'HOSPICE des Enfants-Trouvés of Paris, has changed its title, and not for the first time. In letters of gold on a marble slab, we now read “Hospice des Enfants Assistés.” After 1848, the name was likewise altered, under the auspices of Dr. Thierry; the inspiration of that day caused him to christen it: “Hospices des Enfants de la Patrie.”

WOUNDED AT GENOA.—A correspondent writes:—“The wounded are beginning to show in the streets of Genoa now as convalescent; but, poor fellows, very different from the light-hearted soldiers that passed through the town two months ago. One man I saw on crutches had had his right kneecap hurt by a ball which had broken his left leg, so that he might as well have had a couple of broomsticks as his lower limbs, which were quite stiff and unbendable. Men with their arms or hands bandaged, or limping along stick in hand, are common enough. They are pale as ghosts, and quiet, losing their national gaiety with their blood.”

HUNTER'S STATUE.—The profession will be glad to hear that at the last meeting of the Hunter Statue Committee it was reported that the subscriptions already received amounted to £1082 15s.; whereupon it was resolved that, after payment for the statue (which is to be of marble and to be placed in the College) the surplus of the subscriptions that may accrue and any further funds that may be contributed for that special purpose, be devoted to the endowment of one or more scholarships of comparative anatomy, thus meeting the objections of some members of the profession to the money being altogether expended on a statue, who will now, no doubt, contribute to so laudable an object as a Hunterian scholarship.

A HINT FOR DR. HORACE GREEN.—M. Griesinger, Professor at Tübingen, has been making experiments with injections thrown into the trachea. To prove that the catheter was really in the trachea the Professor placed a flame at the open end of catheter, and found that, during inspiration, the flame was drawn in, and blown away during expiration. It was observed, however, that the injections, acetate of lead, nitrate of silver, and sulphate of iron, sometimes produced a sensation of heat at the epigastrium, and diarrhoea. This induced another experiment. An œsophagean tube was passed into the stomach, and the very same effects were produced, through it, upon the flame presented at its open end! Is it not possible that the bronchial injections of other experiments have occasionally passed, like some of the learned Professor's, into the stomach instead of the lungs of the patient?

GLYCOGENE.—M. Bernard has established the fact that glycogenous matter appears in the very earliest periods of embryonic life, and that it is localised before the development of the liver in the placenta, or in some other of the appended and temporary organs of the fetus. He has also shown that at this period of progress in the organisation, glycogenous matter is found spread through all parts of the fetus; and that, whatever ideas we may hold of its diffusion, we constantly meet with it in the embryonic tissues during a certain period of their development. From this constancy and universality, Mr. Bernard suggests that glycogenous matter is very probably both in animals and vegetables one of the principal constituents of the protoplasm, in which the organic evolutions are accomplished. M. Bernard ingeniously supposes that there exists a relation between the office performed by the glycogenous matter in the fetus and in the adult. In the fetus this matter serves for the development of the organs; in the adult, it supports them.

THE WOUNDED IN LOMBARDY.—The following is an extract from a letter, dated Brescia, July 15:—“The weather still continues intensely hot, and is really becoming almost insupportable; even the Italians themselves suffer, and declare it to be the hottest season within their remembrance. The unfortunate wounded who still crowd the Hospitals die off in great numbers, unable with their weakened frames to withstand the aggravated forms which their wounds assume in consequence of the heat. Sad to say, many of the ladies and nurses have also fallen victims to their devotion to the suf-

ferers, having contracted the Hospital typhus, which is now lurking about, whilst engaged in the trying duties they have voluntarily imposed upon themselves. It may not be so generally known that two or three of our countrywomen have actively assisted in this work of charity; and one in particular, whose name I may not mention, will long be remembered for the good she bestowed upon the wounded at Decenzano. These little traits are pleasant to record; they stand out so brightly in their own true colours, on that darker surface created by man's vanity and wretched ambition."

HOUSE DRAINAGE INTO WELLS.—The magistrates of Essex have lately recovered a verdict against the proprietor of some cottages erected near the Lunatic Asylum of Chelmsford, because he had sunk a cesspool to receive the drainage of those cottages, in such a position as to affect the waters of the well of the Asylum. The principle involved in this case may have a very wide application; for there are many cities in England wherein the sewerage, as we very incorrectly apply the term at the present day, or rather the removal of house drainage, is effected by means of absorbing, or dead wells. If in such cases the waters of any existing wells should be injured by the construction of new cesspools, it would seem to follow, from the decision in the case we refer to, that the proprietors of the wells would have ground of action against the sinkers of the cesspools; and thus compulsorily the towns referred to would be compelled to execute a system of sewers. At every turn, then, this great question of town refuse meets us; and most urgently does it clamour for solution.—*Journal of Gas Lighting.*

THYMUS GLAND.—Analysis of M. Friedleben's work on this gland. Anatomy: 1. The thymus is a gland without any external duct; it is composed of an infinite number of lobules, each one consisting of closed follicles, united together by a very fine cellular tissue. 2. Its nerves are the nerves of its vessels, and proceed from the ganglions of the sympathetic. 3. The thymus has no free cavities; what have been taken for cavities are interlobular intersections. 4. It contains a secretion composed of a clear transparent fluid, holding innumerable round nucleoli in suspension, mixed with some cells. 5. The nucleoli pass directly into the veins of the thymus. 6. The follicles of the thymus continually perish and are renewed; the bodies which have been called concentric are only follicles during their metamorphosis. 7. The thymus increases continually from its embryonic origin up to the age of puberty; but its increase is relatively less than that of the body. Between the ages of fifteen and twenty-five it remains stationary. It begins to diminish in volume at the end of this period, rapidly decreasing in adult life. After this period the thymus is rarely met with; and only in the form of fatty tissue.

EMBOLI.—The following conclusions respecting the obstructions of vessels by solid bodies or fibrinous concretions, are well drawn up by Professor Schützembgen:—1. Fibrinous concretions or solid bodies formed in the heart or great vessels, may be detached from their seat, carried along in the current of blood, and so obstruct different secondary branches of the vascular system. 2. This fact is neither absolutely rare nor exceptional; it constitutes a special and very peculiar affection of the arteries, which has been called by Virchow, "Emboli." 3. This affection was for a long time misunderstood; is now shown to exist both by scientific induction, and by clinical and microscopic observation. 4. It has been observed as a consequence of gangrenous inflammation of the pulmonary veins; of organic affections of left side of the heart; and of atheromatous degeneration of the large arterial trunks. 5. Its most frequent cause is derived from fibrinous or calcareous concretions, and polypoid excrescences developed on the mitral valve, and carried along in the current of blood. 6. When the patient does not succumb under a first attack, another generally follows. Thus the attacks are multiplied. 7. The arteries most frequently found affected are:—the Sylvian artery, the internal carotid, the arteries of the upper and lower extremities, the splenic, renal, external carotid, and mesenteric. 8. The obstruction ordinarily occurs at contracted points of the arteries. 9. If in consequence of the obstruction, a collateral circulation is established, only temporary disturbance is produced. 10. But if no collateral circulation is established, then follow organic alterations, mortifications, and gangrene, dry or humid, partial or general. 11. In the parenchymatous organs the obstruction of the

arterial branches produces sanguinary or circumscribed fibrinous infarctus. 12. In the brain, the infarctus usually occasions yellow softening. 13. In the spleen and in the kidney, the infarctus produces a special lesion, exactly circumscribed, ordinarily of a conical shape, varying in colour according to its age, and often denser than the rest of the parenchyma. 14. Emboli in the cerebral arteries produce functional disturbances analogous to an attack of apoplexy. The symptoms do not differ from those of cerebral hæmorrhage, or acute softening.

THE REVERSE SIDE OF THE PICTURE OF GLORIOUS WAR, AS TAKEN FROM LIFE. "Ghastly indeed is the sight of mangled corpses, mutilated soldiers, torn accoutrements, and broken arms; hideous to see the dead dragged in hundreds to a common grave,—the wounded, groaning and faint, removed. Painful is the sight of a military hospital, where, side by side, lie the dead, the dying, and the convalescent; here in a corner, shrouded by a coverlet, is one whose soul has already passed away; next him a pale wan soldier raises himself on a straw pallet and asks for water; next him a tall bronzed soldier, whose head is propped up on pillows, points to his recently amputated limb, and asks a kindly Sister of Charity, who with cheerful alacrity attends to all his wants, "Is not blood trickling from the stump?" The poor wretch has lost his leg, yet still he thinks he can move his toes! A wounded officer is near him, lying on his back; he has been shot through both shoulders; his last agony is close at hand. A servant whisks the flies from his face, which now works hard in the last convulsions. The chest heaves rapidly, the mouth mumbles, the under-jaw moves violently up and down, giving an unearthly grimace to the livid face, and presently all is over. Close by another sufferer with shattered limb, and next him again one whose life-blood is flowing from a wound in the body. Here a Sister of Charity hovers about the bed, bathing the wretched soldier's face with water, while a monk in the brown dress of the Franciscans is solemnly administering the last sacrament. The last moments of that man may be counted, but his fate excites little awe among the many who surround him. These are not severely hurt. Unaffected by the ghastly scenes around them they relate the incidents of the battle-field—tell you how they fell, and have a word to say as to why the day was lost, though had different orders been given it should have been won. Such are the scenes which meet the eye after a battle,—scenes which are repeated in every ward of a hospital, in which the actors are to be counted by thousands."

ALCOHOLIC FERMENTATION.—The beautiful experiments of M. Pasteur on alcoholic fermentation, tend to show that this phenomenon is the direct consequence of a vital action. He has lately, in continuing his researches, discovered new facts which throw further light on the intimate causes of this wonderful phenomenon. Every one knows that a very little yeast is sufficient in order to cause a large quantity of sugar to undergo fermentation. When the quantity of yeast is increased, the transformation of sugar goes on rapidly. But when the quantity is increased to 50, 100, or 200 times the minimum quantity fixed in his previous experiments, remarkable results ensue. First of all the sugar disappears with surprising rapidity; and when it is entirely destroyed, the fermentation which (according to the purely chemical theory) ought to stop, still continues, carbonic acid is disengaged with great activity, and at the same time alcohol is formed! In this way the carbonic acid may reach to two or three times the volume that the sugar experimented with can furnish. How is such a result to be explained? Whence comes this invisible sugar, which even doubles in quantity after the first quantity is destroyed? Everyone will answer by referring to the beautiful researches of M. Payen: that the glycogenous matter is very probably the cellulose of the globules. And the fact has been verified by M. Pasteur. He has discovered that in order to transform into sugar more than 20 per cent. of its weight of dry yeast, it is only necessary to boil for a few hours ordinary yeast in a very diluted solution of sulphuric acid, as indicated by Pelouze. Hence it is distinctly proved that the yeast is organised, and that the increase of the sugar is intimately connected with the life of the globules; or, in other words, the physiological function of the globules of yeast—true living cells—is to give out carbonic acid, alcohol, glycerine, and succinic acid in the same measure as they themselves are produced, and

the different phases of their existence are accomplished. Is it not very possible that these investigations on fermentation and sugars may be destined some day to throw light on the function and uses of the glycogenous matter found in the animal economy, and of which we have heard so much in these latter days?—*Gaz. Médic.*

THE MAN MIDWIFE, AND THE ROYAL ABORTION.—The same Tuesday night, May 12th, 1829, about twelve of the clock, did Queen Mary fall in labour of her first child, and was delivered at Greenwich about four of the clock next morning, of a son, which lived about an hour, and was baptised by Dr. Wilson, one of the King's chaplains, and named Charles. He was born in the seventh month, near upon eight weeks before the due time, yet had nails and hair; and might in all probability have lived, had he not been turned in the womb, and so spoiled by the man midwife, in the very birth, whom the Queen was forced to use for her own safety. This mischief happened to the Queen and Royal babe in her return from London the day foregoing by water, where she had been at mass; for the boat she was in shooting the bridge, was suddenly lifted up so high with the water, as, in the swift and sudden falling again thereof, she was dissected, and fell down on the bottom of the boat; by which it was conceived the child was turned and dislocated in her womb.—*Life of Sir Simon D'Eves.*

THE JACOB BELL MEMORIAL FUND.—At a special meeting of the Council of the Pharmaceutical Society, the following resolution was unanimously passed:—"Many members of the Pharmaceutical Society and friends of the late Mr. Jacob Bell having expressed a desire that some Monument or Testimonial should be erected to the memory of their late President and friend, as a proof of their high estimation of his disinterested exertions in promoting the advancement of Pharmaceutical knowledge, and in defending them from injurious legislation, the Council have resolved, that no more appropriate mode of accomplishing this object, nor one more in accordance with the expressed opinions and wishes of the man they desire to honour, could be adopted than the establishment by a general subscription, of Pharmaceutical scholarships, to be called 'The Bell Memorial Pharmaceutical scholarships,' which shall be awarded under suitable regulations, to industrious, well-conducted, and competent Registered Apprentices and Associates of the Pharmaceutical Society." It is hoped that such a sum will be subscribed as will ensure the establishment, not only of minor scholarships for young men less favoured by fortune than industry, but also one, at least for the advancement of high scientific attainments. Subscriptions in aid of this object are received by the Secretary, Mr. Bremridge, 17, Bloomsbury-square.

VITAL STATISTICS OF LONDON.

Week ending Saturday, July 16, 1859.

BIRTHS.

Births of Boys, 891; Girls, 876; Total, 1767.
Average of 10 corresponding weeks, 1849-58, 1433.6.

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	30.058 in.
Mean temperature	71.0
Highest point of thermometer	92.5
Lowest point of thermometer	52.1
Mean dew-point temperature	58.7
General direction of wind
Whole amount of rain in the week	0.00
Amount of horizontal movement of air in the week	2 miles.

TO CORRESPONDENTS.

A Lecture by Dr. Simpson is in type, but we had not received the proof at the time of going to press.

X. Y. Z.—We cannot fortell the fate of Apothecaries' Hall.

No Sham will see that the subject is undergoing full discussion.

Fairplay had better ask the question of the Secretary of the College.

Dr. Wallace's letter on Religious Revivals is unsuitable to this Journal.

E.D.D.—If the name appears in the Register there is no necessity for a certificate.

A Subscriber.—Yes, but he cannot recover for medicines supplied to his patients.

Messrs. Mitchell.—We have already announced the fact that the Norwich Union now pays fees to the Medical referees of proposed insurers.

N.—It is not yet known when the proposed reduction in the stamp duty on the College Licences will be carried into effect. The additional fee to the Fellowship is under consideration.

Mr. Andrew.—The pretended extract from this Journal in praise of the *Private Medical Friend* is an impudent forgery. So far from praising such filthy books, we have always endeavoured to put the public on their guard against the impostors who live by exciting the fears of their victims.

V.S.—We have been informed that Mr. S. E. Smith, Surgeon to the so-called National Ear Institution, Pall-mall, was an "Oculist and Aurist," selling a "Smith's Chrystalline Ointment," and advertising extensively in the North of England—but that some fifteen months ago he passed the College of Surgeons.

THE PRESERVATION OF LEECHES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—To all who have to keep a stock of leeches the following singular information will prove valuable. Some years ago, accidentally, the lid of a leech-jar was broken by me, which was of the same substance as the jar, viz., Staffordshire potter, and for no purpose but to save the expense of purchasing a new jar, a tin lid, abundantly perforated with holes, was got for the old jar and from that time the deaths of the leeches have been marvellously few, inasmuch, I should say, where we lost one hundred when the usual perforated pot lid was used, not two are lost by death now, and such has been the case, not for a few weeks, but for years.

Gateshead, July 19, 1859.

I am, &c.

Jos. BELL.

MR. TODD'S CHLOROFORM INHALER.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I suppose it is my inhaler that Dr. Kidd alludes to as having "figured" in the *Medical Times and Gazette*. I have not seen Dr. Kidd's inhaler, but I have seen Mr. Ferguson's, who emphatically denies that any similarity either in theory or construction exists between the instrument which he made for Dr. Kidd and that which he has made for me.

It may be the opinion of Dr. Kidd that folds of lint and hollow sponges are preferable to well-constructed inhalers, but I distinctly deny that this is the opinion of "the best men."

I am, &c.

16, Old Burlington-street, July 19, 1859.

ARMSTRONG TODD.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—My attention has been called to a letter in your last number from Dr. Kidd, stating that the Inhaler described by Mr. Todd is "almost" exactly similar in construction to one I made for him twelve months since. I beg to state that there is no similarity in the two instruments; that by Mr. Todd being entirely different in principle, inasmuch as it permits of the free dilution of a larger per centage of air with the vapour of chloroform than any other instrument that I am acquainted with.

Giltspur-street, July 19, 1859.

I am, &c.

J. FERGUSON.

MEDICAL OFFICERS IN THE ROYAL NAVY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As no doubt the majority of young Surgeons and Students, preparing to enter the Public Services, are under the impression that the late "Naval warrant" placed the Medical Officers of the Navy and Army on precisely the same footing; I beg to state, for their information, that such is not by any means the case, and as an example of some of the differences between the two services, I submit the following.

The late warrant supposes an Assistant-Surgeon R.N. after six years service, to rank with a Captain in the Army. He wears the uniform of a Noncommissioned Naval Officer, which exposes him to the disrespect—even rudeness and ridicule of the military on shore.

July 18th.

I am, &c.

AN ASSISTANT SURGEON, R.N.

AIR-PLUGS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Dr. Keiller in his last letter once more confounds the use of an instrument as a plug with its use as a dilator, and again entirely avoids the question at issue.

Had the so-called "extract" proved anything, it might have been worth while to inquire at what date Dr. Keiller wrote that extract; and also to ask what paper he refers to in the last number of the Edinburgh Journal, for no such paper has yet been read to any meeting of the Obstetric Society here.

Having given the matter my careful consideration, I believe that any one who reads the correspondence between Dr. Keiller and Mr. Murray must see how entirely Dr. Keiller has failed to substantiate the assertions contained in his first letter.

I am, &c.

4, Scotland-street, Edinburgh.

ALBERT MONASTIER, M.D.

PERFORATED CLOTH.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—When in Paris some two years since, I saw perforated cotton used, which I have imitated by folding the cheapest long-cloth fourteen times and driving a sixpenny punch with the blow of a hammer through the cloth on a sheet of lead; the perforations are the size of a split pea, and twice their width apart. It is an admirable substitute in wounds and large suppurating surfaces for lint, as the pus as soon as secreted, passes through the holes and can be removed with a soft sponge. My firm having for many years been the Surgeons to Messrs Curtis and Harvey's Powder Mills, I have had opportunities in testing its efficacy in severe burns, which with all their anxious care will sometimes occur; I find that the irritable and vascular granulations need not be uncovered so often, saving the poor patient much suffering. I am using it in compound fracture and in a gunshot wound of the leg, where, as a bandage spread with cerate, I can give support without confining discharge. The convalescent patients of the 15th Hussars now in Hospital at the Royal Barracks here, to which I am Civil Surgeon, are glad to relieve their monotony by perforating this cloth. As pinking is the process by which by machinery it could be made, and I have had a promise of Mr. Mitchell Henry, of the Middlesex Hospital, to give it a trial there, of which it is really worthy from its coolness, cleanliness, and cheapness.

I am &c.

J. R. A. DOUGLASS.

Formerly House Surgeon of the Middlesex Hospital, Hounslow. Hounslow.

TREATMENT OF SYPHILIS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—With reference to my letter of the 24th February last, and with regard to the treatment of syphilis by inunction with the ung. hydrarg. fort. and in alluding to which in one of the subsequent numbers of the *Medical Times and Gazette* it is stated I recommended the ointment to be used "every day" until the gums are touched. I beg leave to say this must be an oversight, as my plan of treatment is 5ss of the ung. hydrarg. fort. half to be rubbed into each groin, until absorbed, every third day, the patient to be confined to bed and placed on milk or other bland diet. Four or five inunctions are generally sufficient; the gums frequently become congested after the third application and all the diseased appearances vividly developed but soon begin to fade and disappear gradually.

I cannot lay my hand now on the number of the Journal, but recollect perfectly the statement of "every day." I do not wish the system to be super-saturated with mercury, therefore prolong the intervals, and when the gums are once decidedly touched you may reckon with certainty on the worst forms of this disease with its complications being removed, indeed the worst forms are the most remarkable and curable ones, especially where mercury has been used fully and repeatedly by the mouth before, and the system is in a cachectic condition.

The periosteum is apt to be inflamed during the treatment, it is therefore necessary to confine the patient strictly to bed and avoid taking cold.

I am, &c.

WM. ODELL, M.D. Surgeon-Major.

Quebec, Canada, July 1st, 1859.

DOCTORS OF MEDICINE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In answer to your question, "Who is a Doctor," I contend that no one has a right to assume that title, unless he has legally obtained the degree of Doctor of Medicine. The title should, I think, be given to all legally qualified Physicians by courtesy, but they cannot assume it themselves, any more than they can attach the letters M.D. to their names.

I am a duly qualified General Practitioner; have been in practice upwards of fifteen years, as a Physician and Surgeon; not dispensing medicines or having any connexion with Pharmacy; and yet have never dared to style myself Doctor. My practice having now chiefly become a consulting one, I am desirous of having the right to call myself Doctor of Medicine. For this object, I have entrusted my patients to a friend for six months, and am now reading, attending lectures, &c., for the purpose of graduating. The expense to me, attending this, will not be less than £500. It will, indeed, be a hard case, if I find that the College of Physicians of London and Edinburgh, for the sole purpose of raising funds, are admitting men, without any examination, to be members or licentiates; and that these men shall have the right to call themselves Doctors of Medicine. Further, I am much surprised to hear you advocating the formation of a new class of Medical Practitioners, men who are to be examined by a joint board, appointed by the College of Physicians and Surgeons. For Heaven's sake let us have no more grades in the Profession: we are already too much ridiculed by our brethren on the continent, for our absurd distinctions. Throughout Europe, and I may say, the world, there are but two classes of Medical men recognised,—1st. Doctors of Medicine and Surgery; 2nd. Bachelors and Licentiates of Medicine and Surgery. The first class are styled Doctors; the second simply Monsieur, or Signor. Trusting that this important matter will be settled by the Medical Council at their next meeting in August.

University College, July 18, 1859.

I am, &c. MEDICUS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—According to the New Medical Law, such foreigners only are to be registered who have been practising in this country as Physicians and hold diplomas obtained by examination from an University recognised by the Medical Council. The object of this law evidently is to exclude all foreign practitioners who are not fully qualified, and have not enjoyed a thorough general and Medical education. This law certainly holds good with respect to some countries, as, for instance, France and Austria, where the only fully qualifying diplomas are granted by the respective Universities. But the framers of the new law seem to have overlooked the fact that there are other countries where the University diploma confers only an honorary title, but no right to practise. This is, for instance, the case in Prussia, and in all other German states, where the right of granting the License to practise is exclusively reserved by the respective governments, and is conferred by examination only through the supreme Medical Council.

In Germany no Candidate is admitted to this so-called States' Examination (Staats-Examen), unless he has passed the "Maturity Examination" for Classics, Natural Philosophy, and Modern Languages; and has then studied theory and practice of Medicine at one of the Universities for at least four years. I may add, that these States' Examinations are very rigorous, and last, for instance, in my country, the grand Duchy of Baden, four weeks, viz., two weeks for Medicine, one week for Surgery, and five days for Midwifery.

The Medical Council must be well aware that the possession of these three diplomas is in Germany looked upon as the highest qualification; and yet the Council has not acknowledged my three diplomas, although they entitled me in my country to practise as a Physician, a Surgeon, and an Accoucheur. A University diploma, has likewise been rejected, because it has been obtained "in absentia." But still, I am happy to say, the latter has been granted to me on the ground of my three States' diplomas, as well as of a Dissertation, the contents of which have found their way into several German, Belgian, and English papers. However unjust this decision of the Medical Council appears to me, I would not complain of it, had it not been communicated to me only the 24th April, eight days before the closing of the first year's registration. Of course I hastened at once to London, to pass some examinations, but it was too late for being registered this year.

I fully trust, however, that at the next General Meeting, the Medical Council, acting according to the spirit and not to the letter of the law, will take again into due consideration the just claims for registration of fully qualified foreign practitioners.

I am, &c. EDWARD BRONNER.

3, Park-place, Bradford, Yorkshire, July 18, 1859

COMMUNICATIONS have been received from:—

PROFESSOR SIMPSON; DR. LANKESTER; MR. WALTON; MR. LAWRENCE; DR. WALLER; DR. BALLARD; DR. ROLLESTON; PROFESSOR LAYCOCK; DR. ANSTIE; DR. MARCET; DR. E. SMITH; DR. OGLE; DR. SMYTH; MR. BILLET, Taunton; MESSRS. FOX AND CO.; MR. CRAVEN, Hull; MR. HILL; DR. BRONNER; MR. ANDREWS; MR. STRINGER; MR. ABRAHAM; A DOCTOR; MR. DOYLE; MR. NEGUS; MR. STOKES; MR. DOUGLASS; DR. WALLACE; MR. WHITE; MESSRS. MITCHELL, etc.

APPOINTMENTS FOR THE WEEK.

July 23. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m. King's, 2 p.m.; Charing-Cross, 1 p.m.

25. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.

26. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

27. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopaedic Hospital, 2 p.m.; Middlesex, 12½ p.m.

28. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2½ p.m.

29. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

EXPECTED OPERATIONS.

King's College Hospital.—The following operations will be performed this day (Saturday):—

By Mr. Ferguson—Removal of Breast; Removal of Tumour from Parotid Region; Lithotrity. By Mr. Wood—Wood's Operation for Hernia.

NEPENTHE, OR ANODYNE TINCTURE

(OBTAINED EXCLUSIVELY FROM OPIUM),

PREPARED AT THE LABORATORY OF FERRIS, TOWNSEND, LAMOTTE, & BOORNE,
MANUFACTURING CHEMISTS AND WHOLESALE DRUGGISTS, BRISTOL.

This preparation has now been for many years extensively used by a large number of eminent members of the Medical Profession with the greatest success. It does not produce headache, stupor, giddiness, prostration of strength, constipation, or the usual unpleasant symptoms attending the use of other preparations of opium.

Nepenthe has frequently been found of essential service in cases of Cancer, where every other opiate has failed.

The following Testimonials received from Medical gentlemen in extensive practice will be regarded as satisfactory proof of its efficacy:—

MEDICAL TESTIMONIALS.

"Having prescribed your 'Anodyne Tincture' in many cases, I would strongly recommend its more general adoption. It is especially useful in the wakefulness common after parturition, or other unusual exertion or excitement. It produces a refreshing sleep, and I do not remember any case in which it has caused the objectionable effects of the other opiate preparations.

"8, Wellington-street, London-bridge, August 14, 1856.

"SAML. GRIFFITH, M.D. London, M.R.C.P.

Consulting Physician-Accoucheur to the Farringdon Dispensary,
Physician-Accoucheur to St. Thomas's Hospital, &c."

"Ipswich, March, 1859.

"Gentlemen,—I have great satisfaction in bearing testimony to the value of your 'Nepenthe,' in relieving suffering from disease, and in procuring sleep where ordinary narcotics fail or disagree. For several months I have found it very effectual in relieving a great sufferer when all the ordinary anodynes had ceased to benefit, and although the dose has not been increased for months, the relief is as complete.

"'Nepenthe' is a very valuable addition to our means of relief, and the Profession and the public are greatly your debtors for it.

"I am, Gentlemen, yours obediently,

"EDWD. BECK, M.D. Cantab.
Physician to the East Suffolk Ipswich Hospital."

"Portland-place, Reading, Nov. 21, 1856.

"To Messrs. Ferris & Co.

"Gentlemen,—'Nepenthe' has, for some time, been a favourite narcotic with me, and I infinitely prefer it to any preparation of opium now extant. It has proved a remedy of great value in all cases of Neuralgia, Chronic Rheumatism, Hypochondriacism, and indeed all affections where the use of a sedative is indicated; and in Delirium Tremens it is certainly invaluable, performing its operation upon the system, without leaving those distressing feelings consequent upon the use of opiates in general.

"I remain, Gentlemen, your obedient Servant,

"WILL. WOOD BRADSHAW, M.D. M.R.C.P. & F.R.C.S. Lond. &c. &c. &c."

Extract of a Letter from the late G. W. CAINES, Esq. M.R.C.S.

"Please to send me some 'Nepenthe,' as I have a patient with cancer in the breast, with whom no other preparation of opium agrees. I have tried them all."

"Uffculme (Devon), Feb. 16, 1854.

NEPENTHE may be procured direct from Messrs. FERRIS and CO., 4 and 5, Union-street, Bristol; from respectable Dispensing Chemists throughout the Kingdom; and from the following Agents:—

LONDON:—Mr. Thos. Keating, 79, St. Paul's-churchyard; Messrs. Evans, Lescher, and Evans, 60, Bartholomew-close; Messrs. Savory and Moore, 143, New Bond-street; Messrs. J. Bell and Co., 338, Oxford-st.

M. ANCHESTER:—Mr. James Woolley.

LIVERPOOL:—Messrs. Clay and Abraham; Messrs. Evans, Son, and Co.; Messrs. Clay, Dod, and Case.

BIRMINGHAM:—Messrs. Southall Bros. and Co.

YORK:—Messrs. Butterfield, Clarke and Co.

NORWICH:—Messrs. Smith and Sons.

PLYMOUTH:—Messrs. Balkwill and Co.

EXETER:—Mr. Geo. Cooper; Messrs. A. Evans and Co.

EDINBURGH:—Messrs. Raimes and Co.

As many imitations of Nepenthe have been attempted, the signature of FERRIS and COMPANY is placed over the cork of every bottle of the true preparation; and none purchased without this protection can be depended upon.

DR. DE JONGH'S

(Knight of the Order of Leopold of Belgium)

LIGHT-BROWN COD-LIVER OIL.

CAUTION.

Serious and repeated complaints having been made of a discreditable system pursued by many Chemists and Druggists of intrusively recommending or surreptitiously substituting a pale, yellow, or coarse brown preparation, when Dr. DE JONGH'S Oil is prescribed, the Medical Profession are respectfully and earnestly solicited to afford their assistance in counteracting and repressing a practice alike injurious to their patients and to the fair repute of a remedy now held in such high and general estimation. In all cases where this Oil cannot be procured from a respectable Chemist, application should be made to Dr. DE JONGH'S Agents,

ANSAR, HARFORD, & CO., 77, Strand, London, W.C.

By whom any quantity will be immediately forwarded.

WALTERS' INDIA-RUBBER URINALS.

F. WALTERS having originally invented these Urinals, begs to warn the Profession of the many bad and useless imitations which are now sold, and he would advise them, before purchasing, to look that they are stamped with his name; as, unless that be the case, he cannot guarantee them.

These conveniences are made for those who require them only occasionally, during a long journey, as well as for those invalids who use them always. Mr. WALTERS has much improved them by making them of *Etherised India-Rubber*, which adds very greatly to the strength of the India-Rubber, at the same time that it prevents its sticking together; by this means he is enabled to make them less stiff and harsh than hitherto, and yet to retain all the advantages of that stiffness. There is a patent valve, which prevents the return of the fluid; and they may be worn either sitting, walking, or lying, without the slightest inconvenience, and without being perceived by any one.

WALTERS' CONVENIENCES FOR LADIES will be found particularly useful during pregnancy. They are perfectly soft and flexible, and may be worn with perfect comfort.

All Orders must be accompanied by a Post-office order or reference.—Entrance for Ladies at the private door, where a Female attends.

Struve's Seltzer, Marienbad, Vichy,
KISSINGEN, and other **MINERAL WATERS.**—Under her Majesty's especial Patronage.—**ROYAL GERMAN SPA, BRIGHTON, STRUVE'S PUMP-ROOM and PROMENADES,** offering every facility for a Course of Mineral Waters, as perfect and beneficial as at the natural springs, are NOW OPEN, for the Thirty-fifth Season. A prospectus, with the highest Medical testimonials, may be obtained gratis, at the Pump-room, or from **George Waugh and Co. Chemists to the Queen, 177, Regent-street (west side),** London, and other respectable houses in London and the provincial towns, where orders for Struve's Bottled Mineral Waters continue to be executed.
CAUTION.—The success obtained by Struve's Mineral Waters, owing to their perfect identity with those of the natural springs, has induced several parties to attempt imitations, sold as "**Brighton Seltzer,**" "**Brighton Vichy,**" &c., an analysis of some of which has shown an utter disregard of their true chemical composition. To distinguish Struve's Waters from all others, every bottle has a label and red ink stamp over the cork, each bearing Struve's name, without which name none is genuine, though contained in Struve's old bottles.

The Bitter-Water of Friedrichs Hall
 enjoys deservedly a very high reputation amongst Medical Men on the Continent, and in directing the attention of the Medical Profession in this country to the extraordinary virtues of this water, we can mention here only a few of the chief diseases in which it has been prescribed with the most beneficial results—*viz.*, Diseases of the Stomach and Bowels, especially Indigestion, Loss of Appetite, and habitual Constipation; Enlargement and Indurations of the Liver, with or without Jaundice or Dropsy; Diseases of the Kidney, including Albuminuria, Affections of the Sexual Organs, and the numerous accidents which so many women are subject to at their critical age, and the inconveniences resulting from pregnancy; also Hypertrophy of the Heart, Determination of Blood to the Head and Lungs, Hypochondriasis, and Gout, must be mentioned. One peculiar advantage which this water possesses over most other bitter waters is, that it is given only in small quantities—*viz.*, a wineglassful, either before breakfast or on going to bed; that it may be taken at all seasons, and requires neither a particular diet nor exercise in the open air. Further information, with cases, will be found in Dr. Eisenmann's Monograph of this Water, which may be had gratis at Messrs. A. and R. THWAITES and CO.'s, 147, Regent-street, London, and 57, Upper Sackville-street, Dublin, who have just received a fresh supply of this Bitter-water.

Wines from the Cape of Good Hope.

W. and A. GILBEY'S SOUTH AFRICAN PORT, SHERRY, &c. &c., 20s. per Dozen. First growths only. Two samples for 12 stamps. Wine Importers and Distillers, 357, Oxford-street, London (W.); 31, Upper Sackville-street, Dublin; and 12, St. Andrew-square, Edinburgh. Medical Reports, Price Lists, &c. sent post free.

S. Bowles, late Windsor & Co., Phial

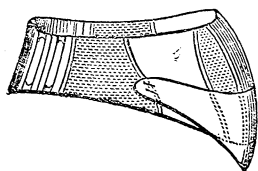

and BOTTLE MERCHANTS, Dealers in Druggists' Sundries, &c., 6, James-street, Covent-garden, W.C. The cheapest house in London for every description of Medical Glass of the best quality. Samples and Prices forwarded free on application.

The Cheapest London House for every

description of the most Improved and best London-made SURGICAL INSTRUMENTS AND APPLIANCES. Best Catheters, 1s. 6d.; Bougies, 1s.; Speculums, 3s. 6d.; Enemas, from 5s. to 15s. J. & E. BRADSHAW, late

Shoolbred and Bradshaw, 34, Jermyn-STREET, begs to call attention to the various improvements in

PATENT ELASTIC STOCKINGS BELTS, KNEE-CAPS, SOCKS, and Ladies' and Gentlemen's SPINE-SUPPORTERS. A new description of BELT invaluable for prevention of Cholera, and the cure of Rheumatism, Lumbago, &c. —N.B. Every description of INDIA-RUBBER BANDAGE, vulcanized on the newest principle.

Directions for measurement sent by post. N.B. A liberal Discount to the Profession.

A female to attend on Ladies.

Mr. Howard, Surgeon-Dentist, 52, FLEET-STREET, has introduced an entirely NEW DESCRIPTION OF ARTIFICIAL TEETH, fixed without Springs, Wires, or Ligatures.

They so perfectly resemble the natural teeth as not to be distinguished from the original by the closest observer; they will NEVER CHANGE COLOUR or DECAY, and will be found very superior to any teeth ever before used. This method does not require the extraction of roots, or any painful operation, and will give support and preserve teeth that are loose, and is guaranteed to restore articulation and mastication; and that Mr. Howard's improvements may be within the reach of the most economical, he has fixed his charges at the lowest scale possible. Decayed Teeth stopped and rendered sound and useful in mastication. 52, Fleet-street. At home from Ten till Five.

SUMMER DIET.

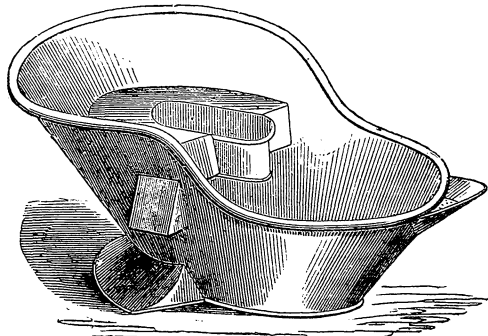

BROWN & POLSON'S PATENT CORN FLOUR.

This is superior to anything of the kind

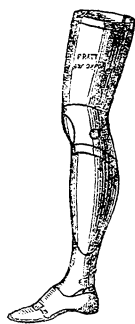

known—LANCET. Obtain it from Family Grocers, or Chemists, who do not substitute inferior articles. It is preferred to the best Arrow Root; for Breakfast boiled simply with milk; Dinner or Supper, in Puddings, warm or cold, Blancmange, Cake, &c., and especially suited to the delicacy of Children and Invalids. Packets, 16 oz. 8d.

Oxley's Patent Multum-in-Parvo Bath.

Sole Makers, GRIFFITHS and BROWETT, 68, BRADFORD-STREET, BIRMINGHAM; and to be had of all respectable Ironmongers.

The convenience of a Bidet, Sponge, Hip, Foot, and Nursery Bath are here combined, which renders it not only the best for general purposes, but indispensable for the Invalid, to whom it may confidently be recommended by members of the Medical Profession as the most comfortable and useful Bath extant.

Pratt's Artificial Leg.

J. PRATT begs to call the attention of the Profession to the following Testimonial, just received:—
"Somerset,

June 20th, 1858.

"DEAR SIR,—It affords me much pleasure in being able to state that the Artificial Leg which you supplied me with is far beyond my best anticipations. From its being so LIGHT IN WEIGHT, and its action in the foot so natural, I can walk, or ride on horseback, with ease and comfort; and few indeed would detect it as being other than natural. It has given me full satisfaction.

I am, dear Sir, yours very truly,

J. W.

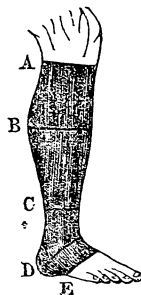

To Mr. J. Pratt,
Surgical Instrument Maker,
420, Oxford-street."

Health, Fresh Air, and Pure Water.

—By Her Majesty's Letters Patent.—CONDY'S FLUID contains NASCENT OXYGEN, *nature's true and only purifying agent*; instantly removes all offensive smells; renders impure water fresh, and the air pure; when diluted for use, is of a beautiful colour, not soiling the finest linen; is harmless, and particularly adapted for toilet use, being both refreshing and exhilarating. The Medical Profession have expressed their unqualified approbation of its merits. One gallon makes 200 gallons adapted for use. The cooling, healing, gently stimulating and invigorating properties of this Fluid render it, when diluted, a lotion possessing peculiar and valuable characteristics, whether for bathing the bodies of invalids, incorporating in poultices, or washing and healing wounds. Patronised by the Board of Health, and most public departments, hospitals, schools, and adopted by the India Council in preference to all other disinfectants. In bottles, 6d. 1s. and 2s.; stronger and purer, 1s. 2s. and 4s.

CONDY'S PATENT HEALTH POWDER also contains NASCENT OXYGEN, is odourless, and destroys all smells; in bottles, 1s. 6d. and 3s., and in casks of 1 cwt. 36s.

Wholesale agents, John Bell and Co., chemists, No. 338, Oxford-st. W.; Butler and Crisp, 5, Cheapside, St. Paul's; Savory and Moore, Bond-street. —Chemical works, Battersea, S.W.

Voullion's Patent Elastic SPIRAL SUPPORTS, "WITHOUT SEAMS OR LACING."

200 Leading Members of the Medical Profession recommend them in preference to all others.

DIRECTIONS FOR MEASUREMENT:—

For STOCKINGS—Circumference round the instep, ankle, calf, and above calf.

For KNEE-CAPS—Circumference below knee, at knee, and above knee.

For THIGH-PIECE—Circumference round top and bottom of thigh.

For ABDOMINAL SUPPORTS—Circumference of body above and below the hips.

Illustrated and Priced Catalogues free. Prices reduced 30 per cent.

MEACHER, Operative Chemist, sole Manufacturer, 105, Crawford-street, Portman-square.

Scammony Manufactured from the

ROOT.—This Pure Resin may be had of all Wholesale Druggists at 28s. per lb.

The Medicinal value of this Scammony was fully explained at a meeting of the Pharmaceutical Society, and reported at length in their journal of March last, from which the following are extracts:—

"From these numerous observations, one hundred and twenty in number, together with many others which have not been tabulated, I am quite convinced that the scammony prepared by the new process from the untapped root is quite equal, as a remedy, to the very best virgin scammony which is met with in commerce, and equal, in fact, to the resin which is extracted from commercial scammony by means of ether; and it possesses this most important advantage over the scammony of commerce, namely, of being entirely free from the frauds which are almost constantly practised upon it in the country where the plant grows, and in which it has hitherto been collected, and, therefore, being perfectly uniform in its physical characters, composition and therapeutic action. There can, therefore, be no objection, but, on the other hand, manifest advantage, in employing it in place of the scammony commonly met with.

"A. B. GARROD, M.D., F.R.S., F.R.C.P.

"Professor of Materia Medica, Therapeutics and Clinical Medicine at University College; Physician to University College Hospital."

"I have endeavoured to ascertain the relative activity of Messrs. M'Andrew's scammony, and of a fine specimen of commercial virgin scammony, by prescribing these drugs alternately in equal doses to the same patient. The results, according to the judgment of myself and others who have assisted me in watching the cases, is that in most instances Messrs. M'Andrew's scammony has proved itself decidedly more active than the virgin scammony. As to pleasantness of operation, or the reverse, there seemed to be no choice between the two specimens.

"That a preparation of scammony should be a little more or a little less active is of comparatively small importance. It is far more important that the drug should have a fixed and uniform composition and activity, so that the prescriber may know, with an approach to certainty, what doses are required to produce a given effect. This advantage of uniform activity Messrs. M'Andrew's scammony seems likely to possess over the scammony which has hitherto been in common use, and which is a drug notoriously of most uncertain composition and power.

GEORGE JOHNSON, M.D., F.R.C.P.

Professor of Materia Medica and Therapeutics in King's College; Physician to King's College Hospital.

MEDICAL AGENCY.

NOTICE OF REMOVAL AND CHANGE OF FIRM.
Mr. Lara (for the last eight years the

sole representative of LANE and LARA, Medical Agents and Arbitrators and Lunatic Asylum Registrars,) begs to inform the Profession that, in consequence of the daily increasing support with which he has been favoured, and for which he tenders his sincerest thanks and acknowledgments, he has taken into PARTNERSHIP Mr. James Maxfield Walters, a gentleman who has had considerable experience in the business. It will, therefore, from and after Christmas, 1858, be carried on, under the Firm of LARA and WALTERS, at 6, PUMP-COURT, Middle Temple, E.C., whither they have removed their Offices from 22, Buckingham-street, Adelphi, in order to provide that larger accommodation which a constant intercourse with a great majority of the entire body of General Practitioners in England has rendered necessary.

Partnerships and Practices sold and valued: Asylums transferred: Arbitrations effected: Assistants provided (if for a permanence without charge to Employers): and every other description of business transacted for the Profession at a fixed and moderate cost. Attendance from 11 till 4.

Hospital for Diseases of the Skin,

25, NEW BRIDGE-STREET, BLACKFRIARS.—800 Patients attend here weekly. The Out-patients are seen every Monday, Wednesday, and Friday, at Four o'clock, p.m. Gentlemen desirous of attending the Practice can learn particulars by applying to the Dispenser, at the Hospital, or to the Surgical Officers, at their residences.

GEORGE BURT, F.R.C.S., Hon. Sec.
ALFRED S. RICHARDS, Secretary.

British Medical Association. — The

TWENTY-SEVENTH ANNUAL MEETING of the BRITISH MEDICAL ASSOCIATION will be held in LIVERPOOL on Wednesday, Thursday and Friday, the 27th, 28th, and 29th days of July, instant.

PRESIDENT.—W. P. ALISON, M.D., F.R.S.E., Edinburgh.

PRESIDENT-ELECT.—JAMES R. W. VOSE, M.D., Liverpool.

WEDNESDAY, 27th, 7 p.m. — First General Meeting of the Association, Address, Report of Council, and other business.

THURSDAY, 28th, 8.30 a.m. — Public Breakfast, —11, a.m. — Address in Medicine, by Dr. E. WATERS, of Chester, Cases and Papers. —AFTERNOON. —Report of Benevolent Fund, Cases and Papers. —EVENING. —Soirée at the Royal Institution, Colquhoun-street.

FRIDAY, 29th, 11 a.m. — Address in Physiology, by A. T. H. WATERS, Esq., Liverpool, Cases and Papers. —6 p.m. — Dinner: Tickets, a Guinea.

It is particularly requested that all Members who propose to read papers will communicate with the General Secretary without delay.

PHILIP H. WILLIAMS, M.D., General Secretary.

Worcester, 1st July, 1859.

Royal Berkshire Hospital, Reading. —

The Situation of HOUSE-SURGEON to the above Institution is now vacant. The number of beds at present available is nearly a hundred, and the salary attached to the office will commence at £60 per annum, with board and lodging. It is necessary that any Gentleman holding it should be unmarried, a Member of one of the Royal Colleges of Surgeons of Great Britain and Ireland, and also of the Apothecaries' Company.

Testimonials as to character and efficiency to be forwarded on or before the 1st day of August, addressed to the Secretary, from whom, in the meantime, any further particulars may be learned.

The Election will be held on Tuesday, the 9th day of August, when those Candidates whose presence is required will receive notice to attend.

N.B.—A personal canvass of the Members of the Board of Management is prohibited.

Reading, July 13, 1859.

Addenbrooke's Hospital, in the Town

of CAMBRIDGE. — HOUSE APOTHECARY. — NOTICE IS HEREBY GIVEN, that a SPECIAL GENERAL COURT of the PRESIDENT and GOVERNORS of the above Institution, will be held in the Board-Room of the said Hospital, at Eleven o'clock in the forenoon of the 5th SEPTEMBER next, for the ELECTION of a GENTLEMAN, to fill the office of House Apothecary, vacant by the resignation of Mr. Edmund Carver. The Gentleman elected will have to reside, and will be boarded in the Institution. The Salary is £86 a-year.

All Candidates must be duly qualified, and must forward Testimonials as to ability and character, sealed up, under cover, to the Secretary, before the 31st of August, and must produce their qualifications to the Court, on the day of Election.

And notice is hereby further given, that in case of a contest, votes will be received by the Court, at the Board-Room, from 12 o'clock at noon, until 5.30 o'clock in the afternoon of the said fifth day of September, when the Election will finally close.

Ladies only can vote by proxy, forms of which, and all particulars, may be had upon application, at the office of the Secretary.

By Rule 24 no Governor can be allowed to vote whose Subscription is unpaid; nor unless he has been a Governor for six months, except he be a benefactor of Twenty Guineas and upwards.

Annual Subscriptions became due on the 29th of September last, and as Subscriptions are paid in advance for the current year, all Governors by yearly subscription of two guineas must pay their Subscriptions up to the 29th September, 1859, together with all arrears, if any, to EDMUND JOHN MORTLOCK, Esquire, Banker, Cambridge, the Treasurer, before their votes can be received.

By order,

FREDERIC BARLOW, Secretary.

St. Andrew's-street, June 30th, 1859.

Retreat for the Intemperate. — A

Married M.D. desires the CHARGE of a LIMITED NUMBER of PATIENTS of the UPPER CLASS, in a delightful Residence in the Highlands of Scotland. Apply to "Medicus," Medical Times and Gazette Office, London

Medical Transfer and Partnership.

30, Bucklersbury, Cheapside.

Mr. Orridge, Medical Transfer Agent,

Referee, and Valuer of Medical Property, may be consulted, at the above Address, by Gentlemen about to receive PARTNERS, or to RELINQUISH or to COMMENCE Practice.

Mr. Orridge is known to many of the Hospital Physicians and Surgeons of London.

He has been concerned professionally for a considerable proportion of the most influential Practitioners (including Partners in many of the leading Medical Firms), to whom he has the satisfaction of being permitted to refer—a privilege that he trusts will be regarded as a proof of the sincerity of his endeavours to conduct these transactions in an honourable and straightforward manner.

Gentlemen desirous of obtaining Mr. Orridge's opinion, or requiring his attendance professionally in any part of England, can obtain terms on application, by (confidentially) transmitting name and address.

Office Hours, from Eleven to Four.

Stourbridge Dispensary.—Wanted, a

HOUSE-SURGEON and SECRETARY. Salary, £120 per annum, with house and coals. Candidates must be Members of the Royal College of Surgeons and Licentiates of the Apothecaries' Company, London. The Gentleman elected will be required to enter into an agreement not to practise within three miles of the town until three years have elapsed after resigning the appointment. Applications and testimonials to be forwarded to Mr. Way, the present House-Surgeon, on or before the 20th day of August. The Election will take place the following Tuesday. Duties commence September 30th.—Stourbridge, July 11, 1859.

Practical Midwifery. — Birmingham

and MIDLAND COUNTIES LYING-IN HOSPITAL and DISPENSARY for the DISEASES of WOMEN and CHILDREN.—There is at the present time a VACANCY for ONE RESIDENT SURGEON in the above Institution. To Gentlemen possessing Medical or Surgical qualifications, and who may be desirous of acquiring a thoroughly practical acquaintance with those important departments of the Profession, previous to engaging in the responsibilities of private practice, this opportunity affords unusual facilities. The Resident Surgeons are three in number, whose duties are to attend all cases, both in and out of the Hospital, under the superintendence of the Honorary Surgeons. The salary is £30 per annum, with board and lodgings. The Gentleman appointed will be expected to hold the situation twelve months. Applications, accompanied with testimonials and diplomas of qualifications, to be addressed to Mr. J. Kennelly, Secretary at the Hospital, on or before Friday, the 29th inst.

Board Room, Broad-street, July 14, 1859.

Medical.—A duly-qualified Surgeon

may hear of an excellent OPENING in a Mining and Agricultural District. Population two to three thousand, and rapidly increasing. No resident Surgeon within five miles. Communications to be addressed to J. S., Messrs. Allbut and Daniel's, Hanley, Staffordshire.

Medical Pupil.—October Session.—

A Gentleman in Practice near one of the Metropolitan Hospitals has accommodation for a HOUSE PUPIL. Every attention will be paid to his home comforts and professional acquirements. Unexceptional references will be required. Address, by letter, B. R., care of Mr. Baker, Instrument-maker, High Holborn, W.C.

Medical.—A Gentleman, in extensive

London Practice, and holding Public Appointments to the extent of £1300 per annum, requires a PARTNER. Principal only to apply, by letter, with real name and address, to Messrs. Pawle, Belfrage, and Asprey, Solicitors, 7, New-inn, London.

To the Medical Profession. — The

Friends of a YOUNG LADY who is afflicted with a CHRONIC NERVOUS AFFECTION, wish to place her under the SPECIAL CARE of a MEDICAL GENTLEMAN, where she could be treated as one of the family. The counties of Lancashire or Cheshire preferred. Address, B. X. X., care of Mr. Houghton, 4, Elliott-street, Liverpool.

For Immediate Disposal, One-half of a

GENERAL PRACTICE, which has averaged for several years past £1000 to £1200 per annum. £300 per annum secured by contracts. Locality, a provincial town, within a few minutes' walk of sea and railway. Valid reasons for withdrawal assignable by the retiring partner. Address to Messrs. Gale, Baker, and Oldfield, Bouverie-street, Fleet-street, London.

To be Sold, at Woolston, in the vicinity

of Southampton, two miles from Netley Abbey, an excellent SEMI-DETACHED GOTHIC RESIDENCE, with every convenience fitted up for a small family. The situation is high, and it commands extensive views of the surrounding neighbourhood. As a country residence it has many advantages, and is in an excellent situation for those who are Invalids, and who wish to enjoy a bracing and salubrious atmosphere. A Medical Gentleman is very much required in this extensive neighbourhood, which is open to a large and extensive Practice. For further particulars, apply to Mr. W. Jurd, Surveyor, 20, Bernard-street, Southampton.

London: Printed by CHARLES REED and BENJAMIN PARDON of 1, 2, and 3, Lovell's-court, Paternoster-row, in the City of London, and published by JOHN CHURCHILL, at the Publishing Office, No. 11, New Burlington-street, in the Parish of St. James, in the City of Westminster.—July 23, 1859.

On the Constitutional Treatment of

FEMALE DISEASES. By EDWARD RIGBY, M.D., etc.

"We know of no other obstetric writer who so strongly insists on the intimate connexion between uterine and constitutional disorders, or who has carried out this principle so consistently and so successfully. On this account we look upon the work as peculiarly valuable, and calculated to do an immensity of good at the present time, by dispelling the one-sided and narrow views so generally prevalent respecting this class of diseases, and placing their pathology and treatment on a sounder and more rational basis."—Dublin Quarterly Journal of Medical Science.

London: Renshaw, 356, Strand.

VOL. XL. No. 1035.—NEW SERIES, No. 474.

Third Edition, revised and enlarged, with Illustrations.

CONTANSEAU'S GUIDE to FRENCH TRANSLATION; a Series of Instructive and Entertaining Pieces, with Notes and Suggestions exhibiting a Comparison of French and English Idioms. Fourth Edition, 3s. 6d.

CONTANSEAU'S compendious FRENCH GRAMMAR; with Foot-Notes, and Exercises on each Part of Speech and on each Rule of Syntax. Third Edition, revised, 4s.

London: Longman, Green, Longman, and Roberts.

Now ready, the Second Edition, in square crown 8vo, with numerous

Maps and Illustrations, price 21s. cloth,

Peaks, Passes, and Glaciers: a Series

of Excursions by Members of the Alpine Club. Edited by JOHN BALL, M.R.I.A., F.L.S., President of the Alpine Club.

"This collection of narratives is of the highest interest. Independently of the personal interest of many of the adventures, the excursions show how much has been left of the actual geography of the Alpine ranges, even in their best-known portions, to be filled up and ascertained by English volunteers who go there for their annual holiday. Mont Blanc itself is not even yet thoroughly explored; but the members of the Alpine Club have contributed to correct its map, and point out where they hope to complete it still further. Even on the spot, the Englishman fresh from his chambers in the Temple or his country curacy, is looked on as the pioneer of new routes and discoverer of new passes by the hunters, guides, and smugglers of the district. The papers are written for the most part by close and trained observers, keenly alive to all the strange experiences and possible surprises of the ice-world, and able to record them with truthfulness and force. Many of the writers are known as well-trained Alpine explorers, and formerly published accounts of scientific and personal interest. A quiet simplicity runs through most of these narratives of remarkable daring, which adds greatly to the pleasure of reading them. Switzerland hardly wants any additional attraction to Englishmen. But we shall be surprised if these papers do not largely increase this summer the number of candidates qualifying themselves for becoming worthy of belonging to the Alpine Club."—Guardian.

The EIGHT SWISS MAPS, accompanied by a Table of the Heights of Mountains, may be had separately, price 3s. 6d.

London: Longman, Green, Longman, and Roberts.

NEW WORK ON THE DOG BY STONEHENGE.

Just published, in square crown 8vo, with about 70 Illustrations engraved on Wood, price 15s. half-bound,

The Dog in Health and Disease:

Comprising the various modes of Breaking and using him for Hunting, Coursing, Shooting, &c.; and including the Points or Characteristics of Toy Dogs. By STONEHENGE, author of the "The Greyhound," &c.

London: Longman, Green, Longman, and Roberts.

GALBRAITH AND HAUGHTON'S NEW SERIES OF SCIENTIFIC MANUALS.

This day is published, in fcp. 8vo, with numerous Woodcut Illustrations, price 2s. sewed,

Manual of Protozoa; with a General

Introduction on the Principles of Zoology. By J. REAY GREENE, B.A., M.R.I.A., Professor of Natural History in the Queen's College, Cork, &c. Being the first of a New Series of Manuals of the Experimental and Natural Sciences; edited by the Rev. J. A. GALBRAITH, M.A., and the Rev. S. HAUGHTON, M.A., F.R.S.

London: Longman, Green, Longman, and Roberts.

NEW EDITION OF SKEY'S OPERATIVE SURGERY.

In crown 8vo, with many Woodcuts, price 12s. 6d. cloth,

The Principles and Practice of

OPERATIVE SURGERY. By FREDERIC C. SKEY, F.R.S., Member of the Council of the Court of Examiners of the Royal College of Surgeons of England, Surgeon to St. Bartholomew's Hospital, &c. &c. Second Edition, revised and enlarged.

"We accept it as the candid record of the experience of one of the foremost amongst us—as the work of a man who has thought deeply and independently, and has honestly endeavoured to make the knife—what, indeed, it ever should be—the last resource of the Surgeon."—The Lancet.

"The independence of thought and research which characterises it gives it a peculiar merit, and justifies our recommending it to every earnest student of his profession."—British and Foreign Medical Review.

"There is much sound and wholesome doctrine in Mr. Skey's work—his reputation as a good Surgeon cannot fail to be advanced by it."—Medical Times and Gazette.

"We are glad to see this Second Edition, and can honestly recommend it as an invaluable guide to operative practice."—Medical Circular.

London: Longmans, Brown, Green, and Longman.

DR. LITTLE ON DEFORMITIES.

In 8vo, with 160 Engravings and Diagrams, 15s. cloth,

On the Nature and Treatment of

CONTRACTIONS and DEFORMITIES. By W. J. LITTLE, M.D. Senior Physician to the London Hospital, Founder of the Royal Orthopædic Hospital, &c.

CONTENTS.

1. Deformities in general. Treatment Operative, Instrumental, and Physiological. Forcible Extension under Chloroform.
2. Contractions from Wounds and Diseases of Joints, Accidents, Rheumatism, &c.
3. Contractions from Spasm, Paralysis, Burns, Habitual Retention in one Position.
4. Deformities from Rickets, Weakness, and Curvatures of Bones.
5. Congenital Distortions and Dislocations, Club-foot, Club-hand, &c.
6. Congenital Malformations, Monstrosities.
7. Distortions of the Spine, from Strumous Disease, Rickets, Lateral Curvature, Spasm, and Paralysis.

Appendix: On Relapsed and Neglected Cases. Index.

"The best treatise on the subject in any language."—The Lancet, the British and Foreign Medico-Chirurgical Review, and the Philadelphia Medical Examiner.

On CLUB-FOOT and ANALOGOUS DISTORTIONS, including their Treatment both with and without Surgical Operation. 8vo. Forty-one Engravings. 12s.

On ANCHYLOSIS or STIFF JOINT: a Practical Treatise on the Contractions and Deformities resulting from Diseases of the Joints. 8vo. Thirty-two Engravings. 7s. 6d.

London: Longman, Brown, Green, and Longmans.

Now ready, price 5s. 6d., or free by post to any part of the United Kingdom, price 6s., Fourth Edition, greatly enlarged and improved,

A Grammatical Introduction to the LONDON PHARMACOPEIA, and a KEY to PHYSICIANS' PRESCRIPTIONS. By F. S. LEACH.

"This little work will be found extremely useful to students who have received but an imperfect classical education."—The Lancet.

Hughes and Butler, Medical Booksellers and Publishers, 15, St. Martin's-le-Grand.

Recreative Science.—The First

NUMBER, published this day, price Eightpence (Illustrated), contains:—Science and the Boy—The Planets, by E. J. London: Simpkin, Marshall, and Co. Edinburgh: Oliver and Boyd.

Dublin: Hodges, Smith, and Co.

Health, Fresh Air, and Pure Water.

—By Her Majesty's Letters Patent.—CONDY'S FLUID contains NASCENT OXYGEN, *nature's true and only purifying agent*; instantly removes all offensive smells; renders impure water fresh, and the air pure; when diluted for use, is of a beautiful colour, not soiling the finest linen; is harmless, and particularly adapted for toilet use, being both refreshing and exhilarating. The Medical Profession have expressed their unqualified approbation of its merits. One gallon makes 200 gallons adapted for use. The cooling, healing, gently stimulating and invigorating properties of this Fluid render it, when diluted, a lotion possessing peculiar and valuable characteristics, whether for bathing the bodies of invalids, incorporating in poultices, or washing and healing wounds. Patronised by the Board of Health, and most public departments, hospitals, schools, and adopted by the India Council in preference to all other disinfectants. In bottles, 6d. 1s. and 2s.; stronger and purer, 1s. 2s. and 4s.

CONDY'S PATENT HEALTH POWDER also contains NASCENT OXYGEN, is odourless, and destroys all smells; in bottles, 1s. 6d. and 3s., and in casks of 1 cwt. 36s.

Wholesale agents, John Bell and Co. chemists, No. 338, Oxford-st. W.; Butler and Crisp, 5, Cheapside, St. Paul's.—Chemical works, Battersea, S.W.

Ports from 30s.; Sherries, 30s.; Madeira, 42s.; Hocks, 40s.; Moselles, 40s.; Sparkling Hocks and Moselles, 48s.; Ditto, St. Peray, 54s.; Ditto, Burgundy, 60s.; Clarets, 28s.; Chablis, 38s.; Cote Rotie, 48s.; Champagne, 44s.; Sauterne, 40s.; Ditto, Yquem, 80s.; Essence of Turtle Punch, 56s.; Old Tom, 11s. 6d. All kinds of Foreign Spirits and Liqueurs. Particular and direct Shipments of Montilla, Vino di Pasto, Amontillado, Oloroso, Xres Viejo, Manzanilla, Longworth's Sparkling and Dry Catawba American Peach Brandy; Monongahela and Bourbon Whisky; and Sole Agent for the Celebrated Yankee Bitters. Bottled Stock for inspection, 6000 dozen. Cash or Reference. As usual, very liberal prices given for genuine Old Bottled Wines. Half-pints of first-class Champagne only.

N.B.—A considerable quantity of the Old Bottled Wines removed to Mr. M.'s Stock from Long's Hotel, North and South American Coffee House, Shugborough Park, and the celebrated Reading Sale.

Blancard's Pills of Unchangeable

IODIDE OF IRON,

Recommended by the Academy of Medicine of Paris,

And authorised by the Medical Council of St. Petersburg, Extensively tried in the Hospitals of France, Belgium, Ireland, Turkey, &c. Favourably noticed at the Universal Exhibition of New York, 1853, and Paris, 1855.

"Of all the modes hitherto proposed of administering iodide of iron in the pure state, I think Mr. Blancard's the best."—Chemistry applied to Therapeutics, by M. Mialhe, Deputy-Professor to the Faculty of Medicine of Paris, Pharmacien to the Emperor, 1856, p. 319.

These Pills stand now very high in the therapeutics of every country, as may be seen by the above quotations, and also by the numerous scientific articles in medical periodicals and works (a).

Being enveloped in a very thin resino-balsamic coating, they present the great advantage of not being liable to any deterioration, of having no taste, of being small, and not distressing the stomach. As they possess the properties both of iodine and iron, they are especially beneficial in chlorotic, scrofulous, tubercular, or cancerous affections, as also in leucorrhœa, amenorrhœa, anæmia, &c. &c., and they furnish the medical man with an excellent means of modifying lymphatic, feeble, and debilitated constitutions. Dose, 2 to 4 pills a day.

N.B.—Impure or altered Iodide of Iron is an unsafe remedy, and may even prove dangerous. Only such bottles as bear an electro-plated seal fixed to the lower part of the cork, and the signature of the inventor placed on a green label, are to be considered as prepared by Mr. Blancard. The public should beware of spurious imitations.

To be had at M. BLANCARD'S, Pharmacien, Rue Bonaparte, No. 40, Paris. General dépôt in England at M. Gabriel Jozeau's, French chemist, 49, Haymarket, London. In Ireland, at Mr. Vities, Stevens's Hospital, Dublin. In the United States, at E. and S. Fougere, Chemists, 30, North William-street, New York. To be obtained retail from the principal Chemists.

ESTABLISHED 1834.

Universal Life Assurance Society,

1, KING WILLIAM-STREET, E.C.

BRANCHES AT CALCUTTA, MADRAS, AND BOMBAY.

Empowered by Special Act of Parliament, 6 William IV. c. 54. For the Assurance of Lives, at Home and Abroad, in the Civil, Military, and Naval Services.

The Funds Invested and the Subscribed Capital exceed £1,180,000.

DIRECTORS.

John Stewart, Esq., Chairman.

Charles Dashwood Bruce, Esq., Deputy-Chairman.

Augustus Bosanquet, Esq.

Ellis Watkin Cunliffe, Esq.

Herbert George Jones, Serjeant-at-Law.

William Kilburn, Esq.

John Farley Leith, Esq.

Francis Macnaghten, Esq.

Major John Arthur Moore.

William Norris Nicholson, Esq.

William Rothery, Esq.

Brodie M'Ghie Wilcox, Esq. M.P.

ADVISORS—Rt. Gardner, Esq.; Rt. Hichens, Esq.; H. W. Ripley, Esq.

BANKERS—The Bank of England, and Messrs. Currie and Co.

SOLICITORS—Messrs. Cotterill and Sons, and Messrs. Parke and Pollock.

PHYSICIAN—Geo. Burrows, M.D., F.R.S., 18, Cavendish-square.

SECRETARY—Michael Elijah Impey, Esq.

After the operations of a Quarter of a Century, the Directors invite, with great confidence, the attention of the Public to the marked success which has attended this Society, and to the strong claims it possesses to the confidence and support of all classes desirous of effecting Assurances on Lives. Combining the advantages of a Mutual and a Proprietary Company, and without attempting a rash competition with other Offices, it has pursued a steady, progressive course, affording all the benefits which, consistently with security to Assurers and Assured, can possibly be given.

The amount of the Society's Funds actually Invested exceeds £730,000. Upwards of £997,380 have been already paid in Claims and Bonuses, and the existing Policies amount to £2,214,928.

The Tables of Rates for Residents in Europe have been prepared upon the most approved principles to ensure moderation and security.

Assurances can be effected with or without a Participation of Profits; on ascending or descending scales; and for a limited number of payments.

The Society advance money on Mortgage; purchase Reversions and Life Interests; and grant Loans on such Securities and on Policies.

An Annual Division of One-fifth of the Profits is made, 75 per cent. of which is appropriated to Policy-holders, and 25 per cent. to the Shareholders; the remaining four-fifths are set apart towards the average of succeeding years. The Assurers can apply their Profits to the immediate Reduction of their Premiums, or as a Bonus to the sum assured.

All Medical Fees and Stamps are paid by the Society.

INDIAN BRANCH.

The Universal was the first Assurance Society that secured to Residents in India fixed rates and the advantages enjoyed by those in Great Britain.

Separate Tables for the Civil and Military Services were originally framed with the utmost care from the Records of the India House, and valuable statistical returns accessible to this Society alone. To test their adaptation to the present time, and to ascertain whether any reduction could be safely made, they have recently undergone a minute and laborious investigation by two eminent London Actuaries, whose Report has established their soundness and accuracy.

Notwithstanding the extraordinary mortality occasioned by the late Mutiny, the Directors were enabled at the last Annual Division of Profits to announce a Reduction of Premiums on all Policies dated prior to 11th May, 1854, of £36 per cent.—a result attributable, in a great measure, to the correctness of the Rates and the judicious management of the Local Committees in India.

The attention of persons proceeding to India, and of residents there, is requested to a peculiar and most important advantage offered by this Society,—that on the return of Assurers to Europe the premiums on their Policies will be reduced to the English scale corresponding with the age when the Assurance was effected, without reference to the state of their health on their return.

Tables of Rates and all further information will be afforded at the Office in London, or by the Agents in India:—

Messrs. BRADDON and Co., Calcutta.

Immediate attention to country orders. No remittance required until the goods are received. Packages free. Goods delivered free within 7 miles. Post-office orders made payable to E. and H. HARRIS and Co., at the Chief Office, London. Bankers: Union Bank of London.

N.B.—Orders sent to either Establishment will have prompt attention.

King's College, London.—Medical

DEPARTMENT.—The WINTER SESSION, 1859-60, will commence on SATURDAY, OCTOBER 1, 1859, on which day all students are expected to attend the Introductory Lecture, at Two o'clock.

The following Courses of Lectures will be given:—

Anatomy—Professor Richard Partridge, F.R.S.
Physiology; General and Morbid Anatomy—Professor Lionel S. Beale, M.B.
Chemistry—Professor W. A. Miller, M.D. F.R.S.
Principles and Practice of Medicine—Professor George Budd, M.D.
Principles and Practice of Surgery—Professor William Fergusson, F.R.S.

KING'S COLLEGE HOSPITAL.

Physicians... { George Budd, M.D. F.R.S.
R. B. Todd, M.D. F.R.S.
George Johnson, M.D.
W. A. Guy, M.B. F.R.S.
Lionel S. Beale, M.B. F.R.S. } With care of In-Patients.
Physician for Diseases of Women and Children and Physician-Accoucheur—Arthur Farre, M.D. F.R.S.
Assistant-Physicians—Charles Murchison, M.D.; Conway Evans, M.B.
Surgeons ... { W. Fergusson, F.R.S.
Richard Partridge, F.R.S.
William Bowman, F.R.S. } With care of In-Patients.
Henry Lee, F.R.C.S. ... With care of Out-Patients.
Assistant-Surgeons—John Wood, F.R.C.S.; John W. Hulke, F.R.C.S.
Surgeon-Dentist—S. Cartwright, jun.

The Hospital is visited daily. Clinical Lectures are given every week, both by the Physicians and by the Surgeons. The Physicians' Assistants and Clinical Clerks, the House-Surgeons and dressers, are selected by examination from the Students of the Hospital.

SCHOLARSHIPS.—New Students will have the privilege exclusively of contending, in October, 1859, for five Warneford Scholarships—viz., two of £25 per annum, for three years, and three of £25 per annum, for two years. The Examination will commence on the 29th of September, in Divinity, Classics (subjects the same as for the Matriculation Examination this year at the University of London), Mathematics, History, and the Modern Languages.

One Scholarship of £40, tenable for two years; one of £30, for one year; and three of £20 each, for one year, will be filled up in April next, the subjects of the Examination being exclusively Medical.

Further particulars may be obtained from J. Harley, Esq., Sub-Dean of the Department; and a detailed Prospectus will be forwarded by application to J. W. Cunningham, Esq., Secretary.

R. W. JELF, D.D., Principal.

The Middlesex Hospital, Session

1859-60.—The Session opens on MONDAY, October 3rd, with an Introductory Address by Mr. HENRY, at Eight o'clock p.m.

The Hospital, from recent enlargements, contains upwards of 300 beds, of which 185 are for Surgical and 120 for Medical cases. The Cancer establishment receives 33 patients. Wards are specially appropriated to cases of Uterine Disease and of Syphilis. 2109 in-patients were admitted during the past year; the number of out-patients during the same period amounted to 16,469.

MEDICAL OFFICERS.—Dr. Stewart, Dr. Goodfellow, Dr. H. Thompson, Dr. Frere, Dr. F. Weber, Dr. Charles Coote, Mr. Shaw, Mr. De Morgan, Mr. Moore, Mr. Henry, Mr. Nunn, Mr. Flower.

Post-mortem Examinations are conducted by Dr. Coote.

LECTURERS.—Clinical Medicine: the Physicians to the Hospital.—Theory and Practice of Medicine: Dr. Stewart and Dr. Goodfellow.—Clinical Surgery: the Surgeons to the Hospital.—Surgery: Mr. Shaw.—Physiology: Mr. De Morgan.—Anatomy: Mr. Moore.—Practical Anatomy: Mr. Nunn and Mr. Flower.—Pathological Anatomy: Mr. Sibley.—Chemistry: Mr. Taylor and Mr. Heisch.—Midwifery: Dr. Frere.—Materia Medica: Dr. H. Thompson.—Medical Jurisprudence: Mr. Henry and Dr. Coote.—Practical Chemistry: Mr. Taylor and Mr. Heisch.—Botany: Mr. Bentley.—Histology: Dr. W. Woodham Webb.—Comparative Anatomy: Mr. Flower.

General Fee for attendance on the Hospital Practice and Lectures required by the College of Surgeons and Apothecaries' Company, £81. This sum may be paid by instalments of £35 at the beginning of the first session, £35 at the beginning of the second session, and £11 at the beginning of the third session. For every additional session, £5.

This fee admits the Students to the Practical Chemistry course, and to all other lectures delivered in the College except Comparative Anatomy.

All general Students are required to perform the duties of Clinical Clerks and of Dressers during each winter and summer session, except the first winter session.

RESIDENT CLINICAL ASSISTANTSHIPS.

For the encouragement of Clinical Study, and for the promotion of Clinical Instruction in the Hospital, the Governors have instituted Three Clinical Assistantships, to be awarded on competition to Students who have completed their education in the School. It will be the duty of the Clinical Assistants to observe and record the cases in the Hospital, and generally, in the absence of the Medical Officers, to carry out the treatment directed by them. They will reside and board in the Hospital for one year free of expense.

Two House Surgeons are elected by competition from among the Students who have completed their curriculum, and reside and board in the Hospital free of expense. Fee, Twenty Guineas.

Prizes and Certificates are also awarded to the Students who have most distinguished themselves, at written periodical Class Examinations, in all the subjects of study embraced in the Session.

The Governors' Prize of Twenty Guineas will be awarded to the Student who, having distinguished himself generally by conduct and acquisitions in the College, shall present the best joint Clinical Reports in Medicine and Surgery.

Parents and Guardians who propose sending Pupils to the Hospital may communicate with the Dean, or with Mr. De Morgan, Treasurer to the College, at the Hospital, daily from One to Three o'clock. Information may also be obtained on application to any of the Lecturers, or to Dr. Corfe, the Resident Medical Officer.

All students on entering will be required to sign an undertaking to conform to the laws relating to the discipline of the Hospital and College.

T. W. NUNN, Dean.

Queen's College, Birmingham.—

FACULTY OF MEDICINE.—The WINTER SESSION will open OCTOBER 3rd, 1859.

Anatomy—Professor Furneaux Jordan, M.R.C.S.
Physiology—Professor Waller, M.D., F.R.S., Physician to the Queen's Hospital.

Surgery—Professor Sands Cox, F.R.S., F.R.C.S., Senior Surgeon to the Queen's Hospital.

Practice of Medicine—Professor W. F. Wade, M.B., B.A., T.C.D., Physician to the General Dispensary.

Chemistry—Professor Bond, M.B., B.A. Lond., F.C.S., Physician to the Queen's Hospital.

Practical Anatomy—Under the superintendence of Professor Jordan and Dr. Walker.

Resident Medical Tutor—T. J. Walker, Esq., M.B. Lond., University Medical Scholar.

Clinical Medicine at the Queen's Hospital by Professors Alexander Fleming, M.D., Augustus Waller, M.D., and Francis Bond, M.B.

Clinical Surgery at the Queen's Hospital by Professors Sands Cox, Langston Parker, J. S. Gamgee, and J. F. West.

The College is situated midway between the Queen's and General Hospitals, and is open to the students of both.

The Junior Department in Medicine is open to students about the age of sixteen, and its studies are specially devoted to preparation for the Preliminary Examinations of the various Universities and Medical Boards, and to the acquisition of a knowledge of the elements of Anatomy, Chemistry, Botany, &c.

The Faculties of Arts, Law, Engineering, Agriculture, and Theology, will also resume at the same period.

For further information and Prospectuses, application may be made to the Honorary Secretary to the Medical Faculty, Dr. Bond, Queen's College.

Wines from the Cape of Good Hope.

W. and A. GILBEY'S SOUTH AFRICAN PORT, SHERRY, &c. &c., 20s. per Dozen. First growths only. Two samples for 12 stamps. Wine Importers and Distillers, 357, Oxford-street, London (W.); 31, Upper Sackville-street, Dublin; and 12, St. Andrew-square, Edinburgh. Medical Reports, Price Lists, &c. sent post free.

WINES FROM SOUTH AFRICA.

Denman, Introducer of the South

AFRICAN PORT, SHERRY, &c. 20s. PER DOZEN, BOTTLES INCLUDED. A PINT SAMPLE OF EACH FOR 24 STAMPS.

Wine in cask forwarded free to any Railway-station in England.

(Extract from the Lancet, July 10, 1858.)

"THE WINES OF SOUTH AFRICA.—We have visited Mr. Denman's stores, selected in all eleven samples of wine, and have subjected them to careful analysis. Our examination has extended to an estimation of their bouquet and flavour, their acidity and sweetness, the amount of wine stone, the strength in alcohol, and particularly to their purity. We have to state, that these wines, though branded to a much less extent than Sherries, are yet, on the average, nearly as strong; that they are pure, wholesome, and perfectly free from adulteration; indeed, considering the low price at which they are sold, their quality is remarkable."

EXCELSIOR BRANDY, Pale or Brown, 15s. per gallon, or 30s. per dozen.

Terms Cash. Country orders must contain a remittance. Cross cheques "Bank of London." Price Lists, with Dr. Hassall's analysis, forwarded on application.

JAMES L. DENMAN, 65, Fenchurch-st., corner of Railway-place, London

TO SURGEONS, APOTHECARIES, AND DRUGGISTS.

Important Saving, by Prepayment,

in the PURCHASE of NEW WHITE ROUND MOULDED VIALS OF THE BEST QUALITY. PELLATT AND Co. submit the following PRICES of VIALS, for PREPAYMENT only:—

1/2 oz., 10 dr., and 1 1/2 oz. per Gross, 6s.	In quantities of not less than
14 dr., and 2 oz. "	7s. Six Gross, assorted to suit the
3 oz. "	8s. convenience of the purchaser,
4 oz. "	10s. delivered to carriers in London.
6 oz. "	15s. No charge for Package.
8 oz. "	18s. Breakage at risk of Pur-
1/2 oz. graduated in 3 doses, "	12s. 6d. chaser.

The above Prices being based upon a calculation which excludes all charges whatever between the Manufacturer and the Consumer, no attention can be paid to any order not accompanied by a remittance in full, made payable in London.—P. and Co. do not supply Green Glass.—Orders and remittances to be addressed,

PELLATT & Co.,
FALCON GLASS WORKS, LONDON.

Struve's Seltzer, Marienbad, Vichy,

KISSINGEN, and other MINERAL WATERS.—Under her Majesty's especial Patronage.—ROYAL GERMAN SPA, BRIGHTON, STRUVE'S PUMP-ROOM and PROMENADES, offering every facility for a Course of Mineral Waters, as perfect and beneficial as at the natural springs, are NOW OPEN, for the Thirty-fifth Season. A prospectus, with the highest Medical testimonials, may be obtained gratis, at the Pump-room, or from George Waugh and Co. Chemists to the Queen, 177, Regent-street (westside), London, and other respectable houses in London and the provincial towns, where orders for Struve's Bottled Mineral Waters continue to be executed.

CAUTION.—The success obtained by Struve's Mineral Waters, owing to their perfect identity with those of the natural springs, has induced several parties to attempt imitations, sold as "Brighton Seltzer," "Brighton Vichy," &c., an analysis of some of which has shown an utter disregard of their true chemical composition. To distinguish Struve's Waters from all others, every bottle has a label and red ink stamp over the cork, each bearing Struve's name, without which name none is genuine, though contained in Struve's old bottles.

CLINICAL LECTURES

ON

THE DISEASES OF WOMEN.

By J. Y. SIMPSON, M.D. F.R.S.E.

Professor of Medicine and Midwifery in the University of Edinburgh.

LECTURE XIX.

ON THE TREATMENT OF PELVIC CELLULITIS.

GENTLEMEN,—The treatment of any case will vary, of course, with the stage at which the disease has arrived when it comes under your observation, and therefore it will be most convenient to consider it under two divisions, as we considered the symptoms of the disease, viz., according as we have to treat it before or after the development of pus. Before speaking of the treatment of pelvic cellulitis

A. BEFORE SUPPURATION HAS BEGUN,

Let me remind you of what I have already told you in regard to the period when this occurs, viz., that when the disease is discovered at the very commencement there is no pus present at all, and abscesses only begin to be formed in ordinary cases about the twelfth or fourteenth day, when the inflammation has attained a certain degree of severity. In puerperal females, indeed, in whom inflammatory processes seem often to run a more rapid course, you may find pus present at an earlier period after the apparent onset of the inflammation; but in most cases you will not be able to detect its presence till the end of the second week. But having recognised a case of pelvic cellulitis early, soon after the patient has had the first shiverings, when she first begins to feel pain, and when the cellular tissue is just beginning to be congested, the first thing that you must do is to have recourse to

1. *The use of Antiphlogistics*, or all those remedies which you would employ in any ordinary case of acute inflammation. Perhaps I could not state the matter better than by saying that you must treat a case of pelvic cellulitis precisely according to the same principles that you would treat a case of iritis, and from this point of view I believe that the first question you will be likely to ask yourselves on seeing a case of pelvic cellulitis would be, Am I to bleed this patient or not? Now I am not going to discuss at present the efficacy or inefficacy of general bleeding as a means of cutting short inflammations, nor to lay down the law as to whether it should be resorted to or not in the treatment of pelvic cellulitis. I leave it to yourselves to decide as to its applicability to any special case that may come before you. But I must take leave to say—although you may perhaps regard me as heterodox for saying so—that I believe I have seen a free venesection made at the commencement of an attack of pelvic cellulitis cut short the disease, and lead to its speedy resolution. It is but rarely, however, that you will find yourselves called upon to have recourse to this measure. There are but few cases, however, of pelvic cellulitis seen in the earliest stage of the disease, in which the local abstraction of blood by means of leeches is not resorted to, and resorted to beneficially. The only question usually is, as to the point from which the blood should be taken; for you have usually the choice of a variety of places to which the leeches may be applied. Some Practitioners are in the habit of applying leeches to the groins in cases of inflammation in the interior of the pelvis; others prefer having them applied to the interior of the vagina, and the surface of the cervix uteri; while others again content themselves with their application to the anus and perineum. I believe you will in most cases find the last, viz. the application of the leeches around the lower end of the bowel, to be the most simple plan, and the most effective. The hæmorrhoidal vessels are freely connected with the vessels that ramify among the pelvic contents and viscera, and by abstracting blood from the former set of vessels you can act on the latter at least as directly as from any other point. And it is very easy to draw blood from this spot, for you have only to apply the requisite number of leeches in an inverted wine-glass over the anus, and hold it there for about ten minutes, and at the end

of that time you will find that most of them have fastened. When it is desired to bleed at the groin, the leeches are made to fix there just as on any other part of the surface of the body; but when leeches are to be applied to the cervix uteri, a special instrument is required. Before speaking of the manner in which they are to be introduced, however, let me remark that you will find some men talking of applying leeches to particular points on the surface of the cervix uteri, according to the special seat of the inflammation. Now, even supposing it were possible in every case to make such a minute and precise application, the process is much too refined, and savours too much of hair-splitting, to be attempted in practice. When we apply leeches to any part of the surface of the body we are not particular to an inch or two as to where they fasten, and we do not regard it always as a matter of very much moment if they fix on a point even somewhat removed from the inflamed locality; and when we wish to apply them to the cervix uteri, all we have to do is to introduce them into the upper part of the vagina and allow them to fasten where they will. To do this, you may use a common uterine speculum passed up to the os uteri, putting the leeches into it, and pushing them up with the staff. But the speculum stretches the parts, and causes unnecessary distress to the patient by its pressure on the inflamed and swollen tissues, so that its use is extremely apt to aggravate the disease. For this reason I usually prefer making use of a narrow bone or ivory tube, such as was first used in this country by Dr. Mackintosh, who was induced to make trial of it on the strong recommendation of a friend who had seen much benefit result from its employment in the hands of some Portuguese Practitioners. It is simply a bone or ivory tube—or it may be made of wood or glass as well—of about three-fourths of an inch in diameter, and furnished with a loosely-fitting piston. The leeches having been put into the tube, and the tube passed up to the roof of the vagina, the piston is pushed forward, and the leeches are driven out into the upper part of the cavity. They fix very speedily upon the surface of the cervix uteri and roof of the vagina, and fill rapidly. By this means you can bleed very freely, for after the leeches have ceased to draw and have fallen out or been removed by the finger, the flow from their bites may be greatly favoured and may be kept up for a considerable time by making the patient sit over a vessel of hot water, for the bleeding usually continues as long as she can sit upright. The application of leeches to the cervix uteri is in this way a most effectual means for the local abstraction of blood in cases of pelvic cellulitis, as well as of inflammation of the uterus itself, for which, perhaps, it is more frequently employed; but it is not without its disadvantages. An eminent London Physician declared to me that he would never again in any instance have recourse to the application of leeches to the cervix uteri, after witnessing the severe spasmodic pain which resulted from their application in a case where one of the leeches was retained for a time, apparently from its having travelled into the interior of the uterus. It is but rarely that such an accident happens, but it does happen occasionally, and is a strong drawback against this mode of leeching in acute uterine disease; but you can readily understand how, when it did occur, the leech as it fills will cause distention of the uterus, and give rise to great pain from the spasmodic contractions which are excited to effect its expulsion, just as we see it in a case of abortion. The trouble attendant in the application of leeches to the cervix uteri is also greater than that attendant on their application to the anus; and hence, in most cases, you will prefer having recourse to the latter. But in any case, let me add, where it might seem to you particularly desirable to have the leeches applied to the cervix uteri, you could easily guard against the danger of any of the leeches finding their way into the cavity of the uterus by filling up the os with a plug of soap or sponge previous to their introduction into the vagina. As to the number of leeches that you are to employ, and the propriety of repeating them or not, these are circumstances which in every individual case must be determined and regulated by the severity and obstinacy of the attack. I need hardly add, under this head of antiphlogistics, that it will be most necessary in every case to enjoin on your patient the most perfect rest, and the use of a strict antiphlogistic diet and regimen. Then, as regards,

2nd, *The Use of Mercury*.—I must leave the question to yourselves to settle how far you will mercurialise your

patients. It is ordinarily laid down, more particularly by English authorities, in regard to the treatment of iritis and of almost every form of acute inflammation, that the administration of mercury should be had recourse to as one of the most essential elements in it; and in the treatment of pelvic cellulitis I used formerly to have recourse to it in almost every case as a regular rule of practice; and I often have recourse to it still in combination with opium, as in two grain doses every two hours of the calomel and opium pill of the Pharmacopœia. But I begin more and more to lose faith in its efficacy, for the disease goes on sometimes unchecked even when the mouth is salivated; and I really do not know that we have any certain proof of its power of producing absorption of inflammatory effusions. Ophthalmologists tell us that they can see these effusions beginning to be absorbed in the eye just as the drug begins to exert its constitutional action; but it is assuredly doubtful whether these phenomena stand in the relation of effect and cause, or whether they are not merely coincidences. I have heard Professor John Thomson repeatedly and strongly state that he had occasion to treat forty cases of syphilitic iritis, and having no faith in the reputed power of mercury in the cure of that disease, he treated them without mercury, and succeeded in effecting a cure in all the cases, excepting two, which occurred in the persons of two medical men who had had the misfortune, in the pursuit of their profession, to get their fingers inoculated with syphilitic poison, and who suffered from iritis along with other secondary affections. These two gentlemen had great faith in the power of mercury, and insisted on having it administered to themselves, and in them alone, out of all the forty cases of iritis, did the disease run an unfavourable course and end in loss of vision. But though there is probably little benefit to be derived from the employment of mercury, there are other medicines which you can prescribe with advantage. Such are,

3rd, *Anodynes*.—The patient, as I have told you, has usually considerable local pain, and complains frequently of severe dysuria, tenesmus, etc.; and to relieve these distressing symptoms you must allow her the free use of opium, in all cases, at least, where the stomach will bear it. I have a belief that the opium exerts some power as a direct antiphlogistic, and at least, when you give it combined with ipecacuanha or antimony, you use as good an antiphlogistic as almost any other you could employ. In addition, you may have recourse, further, to

4th, *The Use of Alteratives and Depurants*; by which I mean, that it will often be advisable for you to administer the alkaline carbonates and hydriodates, according to a practice much in vogue among continental physicians, and which I believe to be a successful practice in many cases of acute cellulitis. The French employ them frequently, and, as they aver, with the happiest results in cases of croup and other acute inflammations. They believe that these alkaline salts have the power of arresting inflammatory action and blotting out its effects.

5th, *External Fomentations, Counter-irritation, etc.*—In addition to the use of these internal remedies, you will find warm fomentations and poultices externally, sometimes soothe greatly in the earlier stages of the disease, and when there is much local pain. I have seen also strong belladonna ointment laid on externally, or a liniment of equal parts of chloroform and olive-oil applied on the iliac or pelvic region, or any pained spot, relieve the patient of local suffering. Let me here add what I should perhaps have already mentioned, that medicated pessaries containing morphia, belladonna, etc., prove sometimes excellent anodynes when introduced twice or thrice a-day into the vagina; and that medicated pessaries of mercurial and iodide of lead ointment form one of the best of local deobstruents, when it is your object to produce the absorption of the effused serum and coagulable lymph, either in acute or subacute forms of the disease of which I am speaking. In the treatment of pelvic cellulitis,—as of iritis and other forms of acute inflammation,—a degree of counter-irritation is often of most essential service. The good effects of the application of counter-irritants in inflammations of internal organs are so well known to you, that it is altogether unnecessary for me to enter into any disquisition on that topic. The only question is, What is the best and most convenient form of counter-irritant that we can in such a case employ? Now, here I must particularly warn you against the use of that most common and con-

venient of counter-irritants—the fly blister, because of the tendency which it has to excite dysuria or to aggravate it when it is already present. At all events, if you will use it, you must take the usual measures to prevent this unfortunate effect. But if you desire to produce a rapid and active counter-irritation, I believe that you cannot do so better than by applying solid nitrate of silver so as to produce vesication. Or you may use a strong tincture of iodine, painted twice a-day over all the lower part of the abdomen. But, finally, with all your other treatment, you must not forget to attend to,

6th, *The Regulation of the Bowels*.—With reference to this point you must remember not to allow the lower bowel to become filled and gorged with feculent matter, so as to be left to press upon the inflamed part, aggravating the pain and annoying the patient. Nor, on the other hand, must you be frequently administering strong medicines, which would purge and excite the action of the intestines and necessitate much motion on the part of the patient. Frequent and violent action of the bowel would act even more injuriously on the progress of the disease than the distension of it with feces, if this be accompanied by perfect rest; but the proper plan is to administer from time to time, at intervals of three or four days, some simple aperient by the mouth, and afterwards to aid its action by a mild enema.

B. AFTER SUPPURATION IS ESTABLISHED.

So much for the treatment of pelvic cellulitis in its earlier stages. But sometimes the disease will go on in spite of the most skilfully-directed treatment, and end in suppuration; and you will occasionally be called on to treat cases in which abscesses have been formed before they come under your care. If you see a patient, for instance, on the sixteenth day after the disease has begun, who presents all the symptoms of hectic fever, whose pulse beats with undiminished rapidity, and in whom the inflammatory swelling has not lessened in size, but only become more soft and yielding, you may make sure that in that patient the disease has ended, or will ere long end, in the formation of pus. The question then arises, How is such a case to be treated? and we reply, You must have recourse to

7th, *The Administration of Febrifuges and Refrigerants*.—Your patient is thirsty, and you will require to give her ice, or a few drops of nitric or phosphoric acid in water for a drink. She is worn down and feverish, with fits of cold succeeded by burning heats; and you will require to administer quinine to counteract the aguish tendency, and to keep up her failing strength. With this view, too, you may be obliged to have recourse to some gentle stimulant, or to the use of an alternation of tonics to support her until the abscess is ripe, and ready for evacuation. In some cases the use of wine, even in considerable quantities, becomes indicated. Again, perspirations sometimes occur, excessive and exhausting; and to moderate them you may have to administer some sulphuric acid along with the quinine, or to give her the phosphate of the alkaloid in dilute phosphoric acid. The next thing to be attended to is,

8th, *The Evacuation of the Abscess*.—But in regard to this point let us endeavour, as a preliminary step, to determine whether a pelvic abscess ought always to be opened or not. I have more than once already told you that when left to itself, the matter has a tendency to find its way to some point on a cutaneous or mucous surface, there to become evacuated. Such spontaneous evacuations take place most frequently into the vagina or the rectum, and these are precisely the places where we particularly desire to see the evacuation occur. But this, unfortunately, is not the invariable rule; and I feel perfectly sure that in any case it is better carefully to watch the progress of the suppuration, and to take it into your own hands to make a proper artificial opening for the discharge of the abscess in a safe and suitable situation, than to leave the guidance of it to nature, and to run the risk of seeing the purulent collection burst in some dangerous or disagreeable locality. By making a prompt and judicious opening into a pelvic abscess, you may even in some cases save your patients' lives. One of the earliest cases of pelvic cellulitis that I saw occurred in a patient whom I watched in the Lying-in Hospital, along with Dr. Ziegler. The inflammation had extended lower down than usual, to the cellular tissue lying between the rectum and the vagina, and had led to the formation of an abscess which had begun to

point towards both of these canals. Such was the state of matters one day when we examined the patient; and we both decided that it was of no use to make an artificial opening, as it seemed certain that the matter must speedily find an exit for itself, either into the canal of the rectum or of the vagina. And, certainly, within four-and-twenty hours from the time when we made our examination the abscess did burst; but we found, to our dismay, that instead of opening on one of these mucous surfaces, to which it pointed so distinctly, the abscess had burst into the peritoneal cavity, where the effused pus had given rise to intense irritation, and lighted up a peritonitis that proved rapidly fatal. But there is usually not by any means so much risk of the abscess opening into the peritoneum, as of its becoming evacuated in some unpropitious situation, such as the bladder, with which it may come to communicate directly; or high up in the rectum or intestinal canal; or the matter may find its way into both bowel and bladder at once; or by some other double opening; and this, as well as all the other unfavourable complications which I have pointed out to you as liable to result from the unguided process of suppuration in the pelvis, and from spontaneous rupture of the abscess, may almost always be easily avoided by early and well-directed artificial evacuation of the pus. I trust that from what I have said, the propriety of surgical interference is sufficiently impressed upon your minds, and that you are now prepared to enter with me upon the consideration of three questions in regard to it, viz. When? Where? and How? is the abscess to be opened?

a. The proper TIME for Artificial Evacuation.—To the first of these three questions, that, namely, which asks *when* a pelvic abscess ought to be opened by the Surgeon, it is impossible for me to furnish a reply that would hold good in every particular case. It is impossible for me to say that on any given day from the commencement of the inflammation, or the hectic fever, an abscess must be so far advanced as to be ready for the knife; for in some patients and under certain conditions the processes of inflammation and suppuration go on more rapidly—in others, again, more slowly. But one piece of general advice I can give you, and that is to withhold your hand so long as there appears to you no risk of the abscess bursting into the peritoneum or opening into the bladder, or in some other situation less favourable than that in which you are prepared to puncture it. It is better not to open it too early, because there is usually more than one collection of pus, and if the case be left to itself for a sufficient length of time, these once separate collections will finally be found to communicate freely with each other, so that by making an opening into one you are able to empty them all, and thus obtain a prospect of a speedy cure. But if you make an opening at too early a period into one of the collections, you succeed in evacuating that loculent alone, and so give room for the enlargement of the other abscesses, which, after a time, and each in succession, may cause distress and call for a renewal of the operation. For this reason I would recommend you to defer the artificial evacuation of a pelvic abscess as long as it seems to you to be safe to allow it to go on unguided, and as long as the severity of the hectic symptoms, or the failing of the patient's strength do not appear to call for more immediate interference. But in any case where you have decided upon giving a vent to the pent-up matter, the next thing you have to do is to choose

b. The proper PLACE for Artificial Evacuation.—If you find it possible in any case to open with sufficient freedom a pelvic abscess at some point on the cutaneous surface, by all means open it there. But it is only in cases where the cellular tissue of the brim or of an iliac fossa is implicated that it will be in your power to do so. Generally pelvic abscesses have a greater tendency to point internally, and to open into some mucous cavity than to make their way towards a cutaneous surface. Internally I have seen pelvic abscesses open in almost every conceivable direction; and, as the result of all my observations, I have no hesitation in saying that the proper place for their artificial evacuation is through the vagina. I have said that abscesses opening into the rectum usually heal very well also; but there is this risk attendant on a communication between the cavity of an abscess and the cavity of the rectum, that faecal matters in some rare cases get into the abscess and either prevent and protract its healing, or light up a fresh inflammation; and when a sinus becomes established high up in the pelvis it is very difficult of access through the rectum. On the other hand, pelvic abscesses

discharging into the vagina usually heal very rapidly; and in those cases where the healing process, from some constitutional peculiarity in the patient goes on more slowly, the opening is still very easily accessible, and in so far is more amenable to treatment. Again, in opening pelvic abscesses artificially, you may inadvertently wound a vessel of sufficient size to give rise to an alarming amount of hæmorrhage; and if the incision has been effected through the rectum, you will find it very difficult indeed to arrest or restrain the bleeding there; whereas, in the case of the vagina, hæmorrhage into it can always be restrained by plugging. It is not often that this accident happens, but we do meet with it sometimes. A year or two ago I attended, along with Doctor James Duncan, a patient with a pelvic abscess which we determined to evacuate through the vagina; and although I used every precaution in doing so, yet I wounded a vessel of considerable size, and we had to keep the vagina plugged for a couple of days to check the bleeding that ensued. You will usually find in selecting the part of the vagina through which to evacuate the abscess, that the best point for the purpose is that spot in the roof of the canal *immediately behind the cervix uteri*, to which I called your special atten-

FIG. 1.

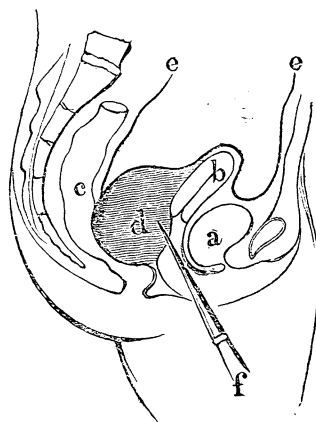

Fig. 1.—Diagram showing the situation of a purulent collection (d) behind the uterus (b), and the point at which it may be punctured through the vagina by means of an instrument (f). a. The bladder. c. The rectum. ee. The ends of the peritoneum.

tion when treating of the pathology of the disease, and where, as I told you, the mucous membrane was supported and protected only by a very thin layer of the pelvic fascia. At this point, then, in the posterior *cul-de-sac* of the roof of the vagina, you will usually find the wall at one point soft and yielding, so that you can press the tip of the finger into it, and here it is that your opening is to be made. It is, I repeat, very easy of access; and as it is, in the great majority of cases, the most dependent point at which an opening could be made, you may hope to evacuate the abscess more effectually by puncturing it here, than by puncturing it at any other point. Having decided, then, in any case that the abscess must be evacuated, and having determined at what point the opening is to be made, you have next to make up your minds as to

c. The proper MEANS for Artificial Evacuation.—For opening pelvic abscesses some have recommended the use of a long curved trocar and canula, such as are used for puncturing the bladder through the rectum in cases of retention of urine, and if the pus be "well digested" and the abscess perfectly mature,—to use the well-known and sufficiently expressive phraseology of the older writers,—such an instrument will usually suffice for its complete evacuation. I saw a case some time ago, along with Dr. Young, where I passed a long trocar and canula of this description along the inner edge of the iliac bone, and so gave vent to an abscess seated very deeply in the iliac fossa. This depth I could not well have reached with a knife; yet in by far the greater number of cases, the knife is by much the preferable instrument. It is not always that the matter is so fluid as to escape freely and full at first through the canula, and then the opening made by it is so small that it readily closes, and thus you are very

apt to have a re-accumulation of the pus. Such a risk you do not encounter when you use a knife for opening the abscess, for with it you can make the opening as free as you will. You may use an ordinary bistoury, in which case you must wrap the whole of the blade round with lint or tape, except the tip of the instrument, so as to guard it and prevent it from wounding any part of the canal. But I believe that you will always succeed best, and operate most successfully with a tenotomy knife. Introduce the forefinger of one hand into the vagina, to guide and guard the point of the tenotomy knife up to the soft and yielding spot, and feel if there is any artery pulsating at the point you propose to puncture, and if so go to one side of this point, pushing in either case the tenotomy knife forward into the abscess with the other hand. On doing this you will usually feel the pus escaping through the opening, but the knife must not be at once withdrawn—not till you have made a slight incision with it to one or other side, wide enough to admit the tip of the forefinger to be pressed through. With the finger forced through enlarge the opening, avoiding the further use of the knife if possible. As you thus enlarge the opening with the finger still more, you will be able to feel with it whether there are further loculations or dissepiments beyond. If all the different loculations have already come to communicate with each other, by enlarging the opening in the manner I have indicated, you ensure a free outlet for all the matter. If you find the pus to be foetid when it escapes, as it sometimes is, then you must bear this further in mind, that that phenomenon is sometimes due to the presence of gangrenous masses in the abscess, and that a perfect cure can never be accomplished until these be completely removed. Break down the walls of these dissepiments or loculations as much as you can before removing the finger. After a free and dependent opening has thus been made into the abscess, there is usually nothing further to be done. To exert pressure through the abdominal parietes, as has sometimes been recommended, is altogether unnecessary, for the abscess empties itself completely without any pressure whatever from above. All that you have to do now is to attend to the patient's general health, which requires to be supported; and to introduce the finger again into the vagina after a day or two, and open up the wound, to prevent its lips from adhering by the first intention, and so lead on again to closure and reproduction of the abscess. By following out these simple rules you will find that in most cases the purulent discharge begins to dry up after a few days, and in about a week the patient begins to recover from all her untoward symptoms, and becomes gradually restored to her former state of health. In most cases, I say, but unfortunately not in all; for in some instances where pelvic abscesses are evacuated either naturally or with the help of art, a sinus is left which keeps on discharging pus, and which renders it necessary for the practitioner to make one or more,

9th, *Counter-openings*.—After an abscess in the broad ligament of the uterus, for example, has been evacuated, suppuration may still go on and spread along towards its external border, and as the matter which is here formed might have difficulty in escaping through a wound in the roof of the vagina, the abscess may go on for years, alternately filling and being discharged, and never healing up at all until another opening has been made in the side of the pelvis. I once saw a very striking illustration of the necessity and value of making a counter-opening, in the case of a patient, the wife of a medical gentleman, whose history showed that several years before she had had an attack of pelvic cellulitis and abscess, which after spontaneously discharging and making a fistula had been allowed to go on for many years, until the hectic fever became so distinct, and the reduction of the patient's health became so great, that two eminent physicians, who had a consultation about her case, came to the conclusion that she was labouring under tubercular disease; and they sent her on a distant voyage in the hope that she might recover in a milder climate. After a year's absence she returned, improved in health, but still with two fistulous openings, one in the rectum, the other high up in the inguinal region, both of them ever and anon discharging quantities of pus. On introducing a long ball probe into the external orifice near the anterior spine of the ilium, and pushing it down along the fistulous track, I could feel it distinctly through the roof of the vagina. At this, the most dependent point in the whole course of the sinus, I made a counter-opening,

through which I pushed the probe, and brought it out at the vagina. The late Dr. Bright was with me at the time, and he afterwards told me he never was in such terror in his life,—for, first, he saw the lady snoring under chloroform, the use of which he had never witnessed before; and then, secondly, he saw that long metal rod sinking away down and down into the depths of the abdomen and pelvis until after my incision it emerged at the vaginal orifice. The result of that operation was most satisfactory, for the matter had now a free outlet for escape; the sinus speedily closed in its entire extent; and the patient recovered betimes her lost health and strength under the kind and able care of my friend Dr. Traill, of Arbroath. Such a case illustrates, in a very impressive manner, the value and importance of making a counter-opening, in the case of a sinus remaining after the evacuation of a pelvic abscess. But you may find cases of pelvic fistulæ of this nature occurring in practice where it may be impossible for you to adopt this plan of treatment. An abscess may have opened spontaneously on some surface, and through the opening from which the matter still escapes you may push a probe without arriving at any other point where a counter-opening would be likely to prove of any service; or in evacuating an abscess with the knife you may have found it impossible to make an opening sufficiently large to admit of the full and free escape of the pus, which continues slowly to be discharged during a lengthened period. When such a state of matters exists, there are two other different modes of treatment which you may adopt. You may have recourse first, for example, to,

10th, *The Injection of Tincture of Iodine*.—Of the value of this measure as a means of diagnosis I have already spoken. Let me now add only one word as to its value as a means of cure. Injection of tincture of iodine in a slightly diluted form into a fistula will almost never produce any bad effects; at least, I have never seen any untoward symptoms result from it, although I have had recourse to it in many cases and many kinds of fistula. Its use, I say, is always safe, and its action is often most satisfactory. The only drawback is, that the injection may require to be repeated again and again, if at first it does not prove successful; and when it becomes necessary thus to have recourse to repeated injections, it is advisable to use a stronger and less diluted preparation. Should the injection of the strongest tincture of iodine fail in effecting a cure of a fistula, you may next have recourse to,

11th, *The Introduction of a Piece of Wire*.—In the beginning of the last winter session I saw a fistula resulting from pelvic cellulitis in the case of a patient where an abscess had been evacuated behind the cervix uteri. Having injected some tincture of iodine into it, and finding little benefit result from its use, I introduced some iron wire into it, and left it lying deep in the cavity of the abscess. In the course of a few days a sufficient degree of inflammatory action was excited to lead to the formation of granulations, and the wire being then removed, the abscess quickly healed and closed up entirely.

12th, *Use of Tonics and Deobstruents*.—Finally, where much effusion remains in the surrounding tissues, your treatment of the case does not end even when the abscess has been healed, and the fistula dried up. But the treatment is now easy and simple, for all you have to do is to endeavour to restore strength to your patient by the well-regulated administration of cod-liver oil, quinine, iron, and other tonics; and where some degree of hardening and induration remains, you must put her upon small doses of iodide of potassium, or, what I think you will find better still, give her five grains of the bromide of potassium three times a-day dissolved in water, or in a vegetable tonic infusion.

And, now, before I have done with this subject, let me fulfil a promise which I made to you when I began it, by reading to you the observations that were made regarding pelvic cellulitis by Archigenes, and which have been preserved to us by Ætius. Remember that Archigenes practised at Rome at the termination of the first, and in the early part of the second century, and that the following account of pelvic cellulitis was written by him within a few years of that distant time when the Emperor Hadrian visited Britain, and commanded here the building of that enormous wall from the Tyne to the Solway, the gigantic remains of which, and of the dilapidated Roman cities raised along its course, form still in Northumberland such striking and startling objects even at the present day.

"OF ABSCESS OF THE UTERUS, FROM ARCHIGENES.

"Abscess in the uterus, as in other parts of the body, results from a previous attack of inflammation. In the first instance, therefore, the symptoms of inflammation will be manifested, and afterwards when the pus begins to be formed the pains are increased, and fever sets in with shiverings, mostly towards evening; a tumour is formed, and a pricking pain is felt; in some cases there is suppression of urine, and in others the evacuation of the fæces is interfered with, or both may be simultaneously affected. But the local pain will indicate the seat of the disease. Then if it cannot be discussed, the suppuration must be artificially promoted. For this purpose poultices of linseed, fennel, barley-meal, boiled figs, mallow root, or turpentine, are to be applied to the lower part of the abdomen and to the loins; or we may even sometimes apply pigeon's dung with oil and honey. The pudenda are to be constantly fomented with a sponge, and vapours are to be introduced into the vagina by means of a reed inserted into the perforated lid of a dish. The patient must be made to sit frequently in baths containing decoctions of those herbs which have a drawing property, such as penny-royal, horehound, laurel, sage, mugwort, dittany, centaury. But if the pain should set in still more violently, poppy-heads boiled in water and bruised must be added to the poultices." Then he goes on to give prescriptions for various medicated pessaries, which may be useful under certain circumstances; and afterwards he proceeds thus: "But when the abscess bursts, if the pus be carried into the bladder, and be excreted with the urine, the patient must drink milk and take cucumber seeds; and poultices such as we have described must be applied, and emollient and odoriferous ointments. But if it make its way into the intestinum rectum, and escape alone, or with the fæces, we must administer a decoction of lentils and pomegranate bark as a clyster. If, on the other hand, it should burst into the pudendal sinus, when the pus is pure, oil of roses, or tetrastemum with fresh butter, and the oil of roses is to be injected, and the parts are to be bathed with a decoction of roses or lentils, or with the juice of ptisan. When a thin and fetid sanies escapes instead, like that from a noma or a corroding ulcer, a less astringent injection must be used, as a decoction of myrtle berries, primroses, lentils, and pomegranate bark. Should the inflammation, however, still persist after the matter is excreted, the use of the poultices and hip-baths above referred to must be persevered with. If the discharges are unequal, the patient must use fomentations and hip-baths of water in which wormwood, horehound, vetches, centaury, or lentils have been boiled. The parts, moreover, must be washed out with juice of ptisan, to which honey and oil of roses have been added; but the os uteri and the anus are to be anointed with a cerate of rose oil or butter, containing a small quantity of the dross of furnaces, antimony, plumbago, or litharge of silver, with some milk from the human female. It may be done also with the juice of lead. But if the matter that escapes be extremely fetid, the pudendal sinus is to be washed out with mead, and the use of it is to be persevered in until the cure is completed."

UNIVERSITY OF DURHAM.—At the Convocation held on the 28th ultimo, the following gentlemen, Licentiates in Medicine, were admitted to the degree of Bachelor in the same Faculty:—John Dickinson, Thomas Thompson Pyle.

CURIOUS DENIAL OF AN ESTABLISHED FACT BY A GREAT AUTHORITY.—"For a long time," M. Trousseau tells the Academy, "I have heard spoken of—I have myself heard—and have believed in a *pleuritic friction sound*; but now daily I lose my confidence in it. I search for it in the patients under my charge, who are attacked with commencing pleurisy, and pleuro pneumonia; I beg my colleagues at the Hôtel Dieu to inform me when they themselves notice its presence in any of their patients; and now, during four years, I have only once heard a true *bruit de frottement*. This is what I find: In chronic catarrh, in pleurisy and pneumonia in its period of resolution, I find, under certain circumstances, the peculiar sound called *bruit de frottement*. In the greatest number of these cases, this *bruit* appears to me to be a sonorous *râle*, which ceases when the patient coughs." M. Trousseau appeals to his colleagues at the Academy; but his colleagues on this point all differ from him.

ORIGINAL COMMUNICATIONS.

FURTHER OBSERVATIONS
ON SO-CALLED VOLTAIC NARCOTISM,
AND ON
CUTANEOUS ABSORPTION.

By A. WALLER, M.D., F.R.S.

Professor of Physiology at Queen's College, and Physician to the Queen's Hospital, Birmingham.

IN the *Medical Times* (February 12, 1859,) Dr. Richardson made known a process for obtaining local anæsthesia that appeared to mark a new epoch in the history of anæsthetics.

To signalise more fully the originality and the importance of this discovery, a special name for it was proposed by its author, and willingly accepted by the Profession, *i.e.* that of voltaic narcotism. The long-sought-for object that had stimulated the ambition of a Galvani, a Davy, and so many illustrious philosophers and physiologists, seemed at length to be realised, for galvanism, that wayward, uncertain, and capricious therapeutic agent, appeared to be tamed for the daily and hourly demands of practical medicine in the alleviation of pain. Voltaic narcotism was presented to us, not as looming in the distance or as accompanied by any doubt or uncertainty, but rather like a Jove-born Minerva, springing into existence perfect in all its parts, and so certain did it appear that it was heralded by the leading articles in two of our chief Medical journals as a great discovery.

According to Dr. Richardson's statement in the *Medical Times* (February 12) voltaic narcotism produced:—

1. Complete insensibility of the integument, rendering operations upon it painless.
2. Insensibility of the deep-seated parts.
3. Insensibility of the parts interposed between the poles (Experiment February 1.)
4. No symptoms or complications calculated to impede cicatrization and recovery.

Voltaic narcotism seemed the more valuable, as it was burdened by no unnecessary theoretical details, as to its rationale, the plain unvarnished facts appeared to have been described, leaving their explanation to others. The only point upon which Dr. Richardson laid stress was that of the all-potent influence of electricity, without which the topical agents, chloroform and aconite, produced no insensibility (a). As a crowning point for the process, it was stated "that within twenty minutes [after amputation of the leg of a dog by Dr. Richardson's process] the animal had eaten two plates of meat and walked about on his three legs with the utmost unconcern." Strongly impressed, in common with many other persons, by the importance of this discovery, I proceeded forthwith critically to examine it, previously to my adoption of it in practice, and the results of my experiments, which were completely opposed to those brought forward by Dr. Richardson, appeared in this Journal on March 19 and May 25, 1859. I found—

1. That insensibility from so-called voltaic narcotism is produced solely by the local absorption of the chloroform and aconite mixture.
 2. That anæsthesia is produced with equal efficacy by the mere topical application of the narcotic mixture.
 3. That the narcotic fluid generally produces inflammation and disorganisation of the skin, and consequently that voltaic narcotism creates unfavourable complications in surgical operations.
 4. That the insensibility is confined to the skin, and does not extend to the deeper-seated parts.
 5. That its application is to be avoided in cut or abraded surfaces, or on the skin of infants where the cutis is very thin.
- I need scarcely say, therefore, that I perused with considerable attention, a second paper (b) by Dr. Richardson, professing to convey the results he obtained during the lapse of four months since his first communication.

The first case alluded to by Dr. Richardson is that of the young woman with a bursa at the wrist, described in his first paper, and which after having entered into various

(a) See *Medical Times*, February 12, 1859.

(b) *Ibid.* June 25.

details, he concluded by stating "did well." We are now informed for the first time that there was for a few days (the number not stated) "some hardness of the skin over the part where the narcotic was applied, also some slight disorganisation of the skin, as if the part had been frost-bitten." I am at a loss to understand why this condition of the skin was not mentioned in the first paper of Dr. Richardson. It is obvious that there must have either been great inattention on his part, or a "suppressio veri" on a point essential to a fair judgment of the case; for our favourable opinion of voltaic narcotism, in the case of a small bursa, so trifling in itself as to be frequently operated upon by patients themselves with scarcely any pain or inconvenience, must be considerably modified, and that the removal of the pain of a simple puncture was dearly bought at the expense of vesication, and partial disorganisation of the skin above it.

The fresh cases now brought forward by Dr. Richardson are six in number: 1. One of whitlow; 2. Another of strangulated hernia; 3. Pain of the arms connected with epilepsy; 4. Tumour of shoulder; 5. Staphyloma of cornea; 6. Section of tendo-Achillis. In all these cases we find that complete insensibility was not once obtained, and that in only one out of the six was there even complete insensibility of the integuments. Furthermore, the impossibility of obtaining insensibility of the deeper seated parts was manifest in every instance.

In case No. 2 of strangulated hernia, there was not even complete insensibility of the skin produced, as it is stated that the patient evinced "passive suffering," which was most marked at the division of the stricture. Case No. 4, where "a tumour, the size of a large orange," was removed, the female had no knowledge of having been "cut," but experienced a sensation like what she called a "wrench."

In both these cases vesication was produced, which in the latter case must have been rather extensive, as Dr. Richardson says that for the removal of the tumour (the size of a large orange) ten inches of cutting surface was required.

The length of time occupied in these manipulations, in case No. 4 lasted one hour, in case No. 1 two hours, and in No. 3, three hours. Dr. Richardson omits all mention of the pain caused by his process, which must have occurred in all these cases. Any one acquainted with the human frame must know that it is impossible to produce vesication and superficial disorganisation of the cutis, without giving rise to a great amount of suffering both before and during cicatrization. Should, however, doubt exist in any person's mind as to this fact, the simple experiment of applying a sponge moistened with the narcotic mixture to the cutis, for a quarter of an hour or upwards will satisfy him.

The following case of varicose veins, operated by Mr. Gamgee, in the presence of Mr. West and other gentlemen connected with the Queen's Hospital, will show how much pain may be uselessly inflicted by voltaic narcotism, which I applied in the manner described by Dr. Richardson. In the first instance two needles were inserted beneath the vein without any anæsthetic. A third was inserted after voltaic narcotism had been applied for fifty-eight minutes, and a fourth was introduced after the skin had been made insensible by Dr. Arnott's process of congelation.

The two first operations need no description. The third was watched, and minutely described at the time. During the whole time of the application of the narcotic mixture the patient felt considerable pain, causing him to wince, and describe his sensations to be of a burning nature. After one minute's application the spot beneath the mixture and positive pole became hot and somewhat red. The burning pain was greatly increased by pressure, and no anæsthesia was ever obtained. In this respect the case resembled that given by Dr. Richardson, where, after three hours' application, no insensibility was produced. The passage of the third needle beneath the vein caused much greater suffering than that of the two first needles where no anæsthetic agent was employed; the skin and subcutaneous tissue being likewise somewhat indurated.

The advantage of Arnott's process was most marked in every particular, it being speedy, simple, and painless; for, after the freezing mixture had been applied for the space of five to ten minutes, the needle was passed beneath the vein without the slightest sensation being produced by its passage, while voltaic narcotism caused a great increase of suffering before, during, and after the operation. I am quite willing

to admit that the effect of voltaic narcotism in the above case was exceptional, though I believe that such exceptions are not infrequent. The different effects in the stage after operation were not less evident. Over the spot where congelation was applied, although the vein was completely obliterated, the sensibility was much decreased, nor was there either tumefaction, pain, or suppuration. Whereas, beneath the skin, where no anæsthetic had been used, there existed around both needles much inflammation and abscesses. Where voltaic narcotism had been applied there was great pain for six or seven days, which pain was considerably increased by the slightest pressure. This pain was unaccompanied by either vesication, tumefaction, or suppuration. The only local action being increased redness and heat, which gradually subsided towards the seventh day, leaving the skin brown, dry, and wrinkled.

The absence of pain and inflammation in the spot where Arnott's process was applied was one of the most remarkable features of this case, and confirms strongly the point contended for by Dr. Arnott, who asserts, as a general rule, that operations by his process are less subject to after inflammation. It was not less interesting to remark that there was a similar absence of inflammation of the cellular tissue after voltaic narcotism, notwithstanding the great amount of pain and vascularisation of the spot. This point is of sufficient interest to need further confirmation by comparative experiments. At present it is not my intention to dwell further on this case, as I understand that Mr. Gamgee intends to present some remarks upon it.

Dr. Richardson, in his paper of February 12, attributed to electricity almost the exclusive power of producing anæsthesia by its action upon the narcotic agents. He based this opinion upon one comparative experiment, where he found that the narcotic mixture produced no insensibility, whereas, on the same person, by the intervention of electricity he produced anæsthesia. Dr. Richardson's mistaken opinion arose from two causes:

1. That he did not act on homologous points on making the experiments.
2. That the narcotic was not applied in the same manner in each experiment.

Any one, on referring to his paper of February 12, will see that his comparative experiments were not made on the same parts, one being on the skin of the wrist and the other on the arm, which last has a thicker cuticle, and its sensibility is less readily affected. He tells us that he renewed the narcotic at the wrist, the part electrified, but does not mention having done so at the non-galvanised spots of the arm. Accordingly, he found only increased redness, but no insensibility on the latter. He was thus led to the erroneous conclusion that electricity accelerates absorption. His error lay in not having sufficiently varied and repeated the experiment, which, had he done, he would have arrived at the same conclusion as myself, *i.e.* that galvanism exerts no accelerating influence on the phenomenon. I find that Mr. Nunneley has even come to the conclusion that electricity lessens absorption, for, in a letter to me he states: "I quite agree with your inferences that the substance, and not voltaic current, is the active power. I have told Dr. Richardson that if the latter have any effect, it in all probability will be to lessen, rather than increase, the power of it." How is it that Dr. Richardson, who cites Mr. Nunneley's excellent article on anæsthesia, does not mention his opinion on the influence of electricity?

In a memoir, recently laid before the Royal Society, I have examined into the action of various agencies which influence cutaneous absorption; and as it will shortly be published, I will only mention here some of the leading results at which I have arrived, and there described.

My principal experiments on absorption have been made by applying to the skin solutions of different alkaloids, as atropia, strychnia, morphia, etc., watching carefully the symptoms of absorption, and noting particularly the effects produced on the pupil. By these means, the influence of age, of circulation, of innervation, etc. may be ascertained and accurately measured. I found a still more powerful influence than either of these on the rate of absorption, exists in the nature of the menstruum, or vehicle of the alkaloid. The menstrua, with which I have experimented, are chloroform, alcohol, water, and turpentine. Chloroform I find to exert the greatest accelerating influence on cutaneous absorp-

tions, of all those yet tried by me. Alcohol, on the contrary, I find to possess the greatest retarding action.

With chloroform, for example, I find that atropia will dilate the pupil after its simple topical application, in the space of from two to four minutes; whereas the same proportion of atropia in alcohol, will produce no influence on the pupil, even after the lapse of thirty minutes and upwards. Water and spirits of turpentine, as vehicles, hold an intermediate place between chloroform and alcohol, or spirits of wine.

Atropia is particularly well adapted to ascertain the exact influence of the various menstria and other agencies on absorption. I have likewise found the same laws to obtain with aconite, morphia, strychnia, and many other alcaloids, and a solution of equal parts of these in chloroform, possess so great an influence on absorption through the skin, that the simple application of some of the former will cause death in a few minutes; whereas an alcoholic solution of the same may be applied from thirty to forty minutes without any effects whatever. Thus, the same agent which is perfectly innocuous in one case, becomes rapidly fatal in another. It was from having inadvertently come across some of the effects of this remarkable action of chloroform, as an accelerator of cutaneous absorption, that Dr. Richardson has been led to draw such erroneous conclusions respecting this so-called process of voltaic-narcotism, which will remain as a remarkable instance in physiology of drawing hasty inferences on the one hand, and on the other of the advantages of eliminating all extraneous causes, and of reducing phenomena to their simplest expression before venturing to explain them.

Finally, I have to remark, that although throughout his last paper, June 25, Dr. Richardson adopts all the objections to the use of voltaic narcotism, which I was the first to signalise four months ago, viz. pain, vesication, and disorganisation of cutis, which appear in his last article, as if newly-discovered by Dr. Richardson, all allusion to my experiments on the subject are studiously avoided. Although I attach little importance to such plagiarisms, I mention them now, as they are so little in accordance with that spirit of "rigid honesty" which Dr. Richardson assures his readers animates him.

Some points of my paper, however, he has not yet adopted, as he still asserts the accelerating action of electricity in the production of anæsthesia, and the existence in some cases, of an interpolary anæsthesia, which he regards as the discovery of a new principle, and I as a complete delusion—as a mere "lusus physiologiæ."

NEW TREATMENT OF HYDROCELE.

By JAMES YOUNG, M.D.

Surgeon, Edinburgh.

SINCE my last communication on the "New Treatment of Hydrocele," which appeared in the *Medical Times and Gazette* of February 26, I have had several opportunities of further investigating the merits of the operation by the iron wire seton; and I feel prepared to recommend the treatment to the Profession as worthy of their careful attention, especially as success has followed in so many cases. This plan of cure may fail; but such has also been the fate of the iodine treatment.

The iron wire seton appears to possess the advantage over the other mode, of not only being more successful, but of effecting a cure in less than half the time. The wire seton may be called a new form of treatment, because the seton employed by Pott, and even the Arabians, was of silk thread; and I have failed hitherto to discover the iron wire seton treatment as employed by anyone previous to the recommendation of Professor Simpson, who has recently given to the world very valid reasons why metallic wire should so far excel silk thread in surgical operations. Within the last few months I have received letters from several Surgeons in England, Ireland, and Scotland, some of whom have tried the operation and found it successful—among others Dr. Quinlan, of Dublin; Mr. Stainthorpe, of Hexham, etc.

I have examined Dr. Curling's treatise on "Diseases of the Testes," and find that mention is there made of the treatment of hydrocele by the silk thread seton, and which was regarded as an improved method of curing hydrocele; but no reference is made by him to the iron wire. It appears to me that one

great desideratum gained by the new treatment of hydrocele over the old, is in one being able to regulate the amount of inflammatory action necessary by the length of time the seton is retained, and which can be removed at any time; while, in the case of the iodine injection, you cannot control the amount of inflammation after the operation is once performed; and as is well known, the action is sometimes so severe that chronic orchitis is the result; and there is at this moment a gentleman under my care for that disease, the result of the iodine injection by a Surgeon in this city two years ago. If we then can so regulate the amount of inflammatory action for the radical cure of hydrocele, so much more likely are we to cure the patient more speedily, than we could do by any method over which we have less control, as in the case of the iodine, and it is just in the point of time that the second benefit results from the new operation.

The time necessary for the cure is six or seven days; and I am certain that in very few cases will the inflammatory action after iodine be subdued, and the parts assume their normal state, in that space of time. I quite believe that a patient having an injection of iodine may walk, or even work, soon after the operation; but the swelling may remain for months in many, if not most instances; whereas, in Case 4 it will be observed that a hydrocele of seven years' standing was completely cured in seven days, and no enlargement of the organ remained.

In arriving at these conclusions I am fortified by several cases on which I have operated since my last paper on the subject, and some of these cases I shall now lay before your readers.

Case 4.—G. G., aged 47, a pensioner, has been for twenty-two years in the public service, and while riding on horseback in London seven years ago he received a bruise of the testicles, and soon after observed the part begin to enlarge and become painful. Leeches were applied while in Woolwich Hospital, where he remained for three weeks. The patient states that he improved somewhat under this treatment, and afterwards wore a truss for six weeks; but the swelling continued unabated till March last. He has had the water frequently removed, but no radical treatment adopted.

On the 3rd of March, 1859, I saw him for the first time, and found him labouring under hydrocele of the left side. I proposed the operation, to which he at once assented. I performed it on the 5th of March, in the usual way, with the curved needle and iron wire seton.

He complained of a little pain, and in the evening a large quantity of water escaped. On the 6th of March there was neither pain or swelling; but on the 7th, a little inflammation, and on the 8th considerably more. I removed the seton in this case on that day (the third from the operation), as the enlargement of the scrotum was sufficient to justify it.

On March 10 the inflammatory action had nearly subsided, and on the 12th he was perfectly well. I saw him a few days since, and he continues quite well.

I may here mention that this patient readily agreed to an inspection of the part before the members of the Medico-Chirurgical Society of Edinburgh at its last meeting.

Case 5.—My next case was that of a mason, from Montrose, aged 67, who, when I saw him, was labouring under a double hydrocele, on both of which I operated at the same time.

He states that his testicles began to enlarge in November, 1858, without any apparent cause. The size of the scrotum gradually increased from that time, and in January, 1859, he was twice tapped by a Surgeon in Montrose without any radical cure having been effected. He came to Edinburgh in March last.

I saw him on the 10th of that month, and operated on the 13th on both sides, and in the usual way. He stated that the operation occasioned him almost no pain. I watched this patient carefully, and removed the wire seton of the right side on the 16th (three days), and the other on the 17th (four days). The inflammatory action rapidly subsided, and he was able to go home cured; and, although I have not seen him, or heard from him since, I requested, before he left town, that he would make me aware if the disease returned.

Since Case 5, I have operated on another patient with equal success. The patient was by trade a smith. The hydrocele was produced by a severe stroke. This patient after being cured, became careless, got intoxicated, and received another

blow, which reproduced the disease a month or two after being cured.

No blame was attributable to the operation in this case, seeing that he continued well and cured till a fresh irritation brought back the disease.

I visited a patient of Dr. Dyer's a week or two since, on whom my friend, Mr. Edwards, operated for hydrocele with the curved needle, and iron wire seton. I saw the man on the third day after the operation, when the wire was removed; and on the sixth day, three days after the wire was removed, the inflammatory action had nearly subsided. The cure has proved most successful. Mr. Edwards thinks this a decided improvement over the old operation, and I expect he will bring the subject under the notice of the Profession at the next meeting of the Medico-Chirurgical Society.

Two reasons why this operation may be considered an improvement, are, 1. Because of the comparative freedom from pain, and 2. Because it effects a cure much more speedily, as is further illustrated by a case operated on in Edinburgh a few weeks since, where the iodine was injected for the cure of the hydrocele. Acute pain continued for four days, from Thursday till the following Monday, and the subsequent enlargement of the scrotum (equal to the pre-existing hydrocele) did not begin to abate for fourteen days.

We are bound in kindness to our patients to adopt the simplest and speediest method of cure in every Surgical operation, and so in this disease. There may be more trouble to the Surgeon in watching the action of the seton, than there is with the tincture of iodine; but there is a great saving of pain and time to the patient, and time is of the utmost importance with most men.

CURE OF HYDROCELE BY INTRODUCTION OF HYDRARG. NITRICO-OXYDUM.

By WILLIAM HEPWORTH RADLEY,
Surgeon to the Great Northern Railway Company, etc.

HAVING tried the above method in two instances, and never having seen it mentioned in any work on Surgery, I venture to present the manner of operating and progress in the two cases. It seems to me to possess, for several reasons, a preference over that by injection, seton, etc. 1st, Its simplicity; 2nd, It does not cause so much pain "immediately" after introduction, as the various remedies employed for injection, the pain coming on more gradually and not being so severe; 3rd, The inflammation excited, although sufficient to produce the equilibrium between the secretion and absorption of the fluid of the tunica vaginalis necessary to make a cure of an hydrocele, still it does not run so high as is very often the case when iodine, port wine, sulphate of zinc, or acetate of lead are employed; 4th, The patient need not be confined to his bed, or even restrained from following his daily occupation. The method of introducing the powder is as follows:—Having extracted all fluid by tapping in the ordinary way, the only precaution that is necessary being to use a moderate-sized trocar,—grease the end of a probe, the blunt end being preferred, and dip it lightly into some of the hydrarg. nitrico-oxydum finely powdered; then introduce through the canula into the sac of the tunica vaginalis; next feel for the end of it through the scrotum; nip the scrotum together, having the probe between the two portions, and withdrawing it, the powder will be left in the cavity. A repetition of the above once or twice will be all that is necessary.

J. G., labourer, aged 65; has had hydrocele for the last twenty years, and has generally required tapping four times a-year.

May 21, 1859.—Tapped him, and drew off thirteen ounces of clear fluid; then by the above process introduced the powder twice. Complained of no pain.

22nd.—States that he experienced a sensation of burning for about an hour after the operation yesterday.

23rd.—Went to his work, which was hoeing wheat.

29th.—Complains that his hydrocele is as big as ever, but has no pain in it; drew off twelve ounces of thick red fluid.

June 5.—His testis is much swollen and hard; can bear it handling without pain, and has continued his work without inconvenience.

12th.—Swelling is now diminishing in size, hardness fast disappearing.

19th.—Has been to the Surgery, and now declares his scrotum to be as natural as it ever was.

J. M., farmer, aged 35, gives a similar history to the above, of twelve years' duration.

June 8, 1859.—Came for the purpose of having it tapped, that it might not, as he said, interfere with superintending his harvest. Having drawn off the fluid, I advised him to have the powder introduced, but had some difficulty in obtaining his acquiescence, as he had had an injection used; it had failed, and having given him so much pain, he said he would rather submit to his hydrocele than undergo the same punishment. However, he consented, and after I had introduced the probe twice, sat talking to me twenty minutes, speculating on the chance of a cure, doubting its efficacy, because as he said it did not pain him near so much as the other did; he then left to walk to his home, some nine miles distant.

10th.—Complained of some considerable amount of pain, which he referred to his walking home, but that the pain was not so severe as to prevent him from going into his hay-field. The scrotum is much swollen and hard, very little pain. Ordered him an ordinary cold lotion, to apply frequently.

13th.—Swelling much abated; has again been into his hay-field.

16th.—Swelling not reduced, but much softer; can now feel testicle at back part.

19th.—Swelling rapidly going, and also hardness.

25th.—I saw the scrotum to-day, and find it to all appearance quite natural.

Red Lion-street, Boston.

THE LONDON

PRACTICE OF MEDICINE AND SURGERY.

ST. BARTHOLOMEW'S HOSPITAL.

TRACHEOTOMY PERFORMED FOR THE REMOVAL OF A TAMARIND-STONE FROM THE TRACHEA.

(Under the care of Mr. SKEY.)

ON July 14, a boy, W. S., aged 5, was brought into St. Bartholomew's Hospital (Lucas Ward), with symptoms of suffocation, consequent, as reported by his mother, on his having "swallowed" a tamarind-stone. The subject of this accident was a strong healthy child. His mother stated that within half-an-hour of the present time, he had been playing with other children, one of whom had shared some tamarinds he had purchased with him; that he had been in perfect health up to that moment, and that he uttered a scream, and appeared on the point of suffocation.

Concluding that the child had one or more of the tamarind-stones in the wind-pipe, the mother held the child up by the legs, hoping to disengage the foreign body. The attempt was not successful, and she ran off with him to the Hospital. When first seen by the House-Surgeon, the boy was sitting up in the father's arms. There was no discoloration or lividity of the skin of the face or lips; but the child had an expression of extreme anxiety, with a hurried respiration. The act of inspiration was stridulous, and he was at intervals attacked with a sudden cough, the sound of which was ringing and metallic, much resembling that of croup, and from its peculiar character was audible at a long distance. During the intervals of the cough the child fell back asleep, from which he was again and again roused by a return of the paroxysm. The presence of the stone could not be felt by the finger pushed down on the glottis. The respiratory sounds on each side of the chest were unchanged, and air entered freely into each lung, and no positive information could be obtained of the position of the offending body. The operation for its removal was performed by Mr. Skey about an hour and a-half from the time of the accident.

The child took chloroform without difficulty. The external incision was somewhat long, and extended from below the cricoid cartilage to the sternum, its length being about one and a-half inch. Some bleeding followed the dissection of the structures, down to the trachea, quite sufficient indeed to preclude the puncture of the air-tube. The trachea being bared, the further progress of the operation was suspended

for a few minutes, at the expiration of which the bleeding had ceased. The trachea was then opened freely, apparently to two-thirds the length of the outer wound. A pair of curved forceps were introduced into the trachea, with which two or three attempts were made to seize the stone; but ineffectually, and they were laid aside. The opening in the trachea was then lengthened by the division of another ring, and two fine hooks being introduced into the opposite cut edges of the tube, the parts were drawn widely asunder, and steadily held

by Mr. Savory. Within a few seconds, the child was seized with cough, and the tamarind-stone was thrown out with force through the opening. It was found to be a stone of the smaller size, and flattened at the sides. The directions given were, that the extremities of the outer wound should be brought together, and that if required, the child should have a mild sedative.

July 15th.—The boy has passed a good night, with a fair allowance of sleep. Skin hot and dry. Respiration, forty per minute. The child inspires through the larynx, but expires partly through the larynx, and partly through the wound. Pulse, 140. Tongue much furred. Over the right side of the chest the cellular tissue is emphysematous. Respiratory sounds, healthy. Ordered, one-twelfth of a grain of tartarised antimony in syrup every two hours.

16th.—Child improved. Skin moist. Respirations, twenty-four per minute. The passage of air through the wound very slight, except during coughing. Omit antimony.

17th.—The boy is sitting up in bed playing with toys. Diet: eggs, milk, beef-tea. Emphysema reduced; wound, healthy. Ordered, liq. cinchonæ π x., ter indies.

20th.—No air passes through the wound. Child convalescent. After the operation Mr. Skey made the following remarks:—

“Tracheotomy is not an operation very easy of performance, and the less so when undertaken on a child by gas-light. It is desirable to dissect in the exact mesial line, not merely to avoid injury to the sterno-thyroid muscles, but to maintain a clear knowledge of the precise locality of our dissection. The operation of tracheotomy, when undertaken for the removal of a foreign body, is essentially different from that performed for the admission of air to the lungs. The required opening in the latter case is small. In the former it must be large, and inasmuch as when it is undertaken for the removal of a foreign body, it is usually performed on the persons of young children in whom the trachea is short. The opening made should involve nearly the whole of the tube, from the cricoid cartilage to the upper border of the sternum. The division of the thyroid isthmus in the child is of no moment.”

Mr. Skey expressed an opinion unfavourable to the employment of forceps of any kind introduced into the windpipe, and said he had never succeeded himself, nor seen the attempt to seize the foreign body succeed in the hands of others, and he greatly preferred to trust to the expiratory efforts of the child, acting through the medium of a large and dilated aperture. Mr. Skey said, the success of an operation of this nature much depends on the co-operation of the assistant. “I have had the advantage of the able assistance of Mr. Savory, who held widely asunder the edges of the divided trachea. In an operation by Mr. Paget last year for the removal of a plum-stone, that duty devolved on me. The length of the opening in the trachea having been increased, the stone was thrown out by the act of coughing, while I was engaged in dilating the wound by means of hooks, and I am indebted to the skilful co-operation of Mr. Savory, whose good management enabled me to complete the operation in the above case.”

HOSPITAL NOTES.

ORCHITIS OF AN UNDESCENDED GLAND.

It not unfrequently happens that when the descent of the testis is delayed until a period of life closely bordering on puberty, inflammation and considerable inconvenience attend its escape through the external ring. We have seen such swellings mistaken for hernia, and a truss applied, to the great aggravation of the boy's suffering. An extreme instance of orchitis, under the condition alluded to, came under notice at Guy's Hospital the other day. A rather puny, thin boy,

aged 12, applied, with a countenance and whole bearing expressive of great discomfort, on account of a swelling in one groin. He was stooping forwards, and evidently moved with the greatest difficulty. On examination, Mr. Bryant, under whose care he was admitted, found that no testis was as yet present in the left side of the scrotum, and that in the left groin, just within the grip of the pillars of the external ring, was a swelling about the size of a bantam's egg. The swelling was excessively tender, and there could be no doubt that it was the undescended testis in a state of inflammation. The boy said that he had had pain in the groin for two weeks, but that the swelling had only commenced three days ago. He was taken into the Hospital and put to bed. Ice was applied, and opium administered, and after a short time the swelling of the gland had subsided.

CHALKY CONCRETIONS FROM A SUPPURATED LYMPHATIC IN THE NECK.

We published some years ago a series of cases in which, during the course of phthisis, chalky concretions had been expectorated. The object of the series was to illustrate and determine the true value and meaning of this peculiar symptom. Our conclusion was, that the expectoration of fragments of chalk indicates that the patient has had tuberculous deposits at some distant period, which have been absorbed, and that now some relapse of pulmonary disorganisation is in progress. We could find no probability in favour of the notion which some writers have expressed, that cretaceous expectoration is a sign of good augury; on the contrary, in all the cases which we cited the patient was worse at the time of its occurrence than had been the case before, and got worse still subsequently. If tubercle is absorbed, its cretaceous remains are impacted in the cicatrised tissue, and never make their appearance in the sputum. A relapse of inflammation is needed to cause their dislodgment, and of such relapse, they are directly symptomatic. The following case has an interesting bearing upon the same question. A girl, aged 14, stout and pale, and of markedly strumous family, has been under Mr. Hutchinson's care at the Metropolitan Free Hospital for six months past on account of a swollen lymphatic under the jaw. Very slowly the gland suppurated, and about a fortnight ago it was opened. A few drops of thin pus having escaped, the opening became choked by a white substance, which required removal by the probe, and which proved to be a nodulated mass of chalk. Four other similar masses, all of them moulded, nodulated, and hard, were subsequently removed. The pus was thin and flaky, such as is usually designated as “strumous.” That these concretions are really the result of absorption of tubercle, and not of that of ordinary pus, there can be but little doubt. The girl had been more or less under Mr. Hutchinson's observation for two years past, having suffered from a very intractable lachrymal fistula; and during this period it is quite certain that the gland had never been materially swollen. With regard to prior years, her relatives were carefully questioned, and they agreed with herself in saying that they had never noticed any swelling in the neck until the present one. It is very probable that a tuberculous lymphatic might have escaped observation, but scarcely possible that a suppurated one should have done so. Apart from its interest as an example of a rare pathological phenomenon, the case is of some importance as strongly supporting the view we took with regard to the parallel one, when the lungs are the organs involved.

AMPUTATION OF THE LEG AFTER RESECTION OF THE ANCLE.

Amongst the cases of interest which have recently been treated in King's College Hospital, is that of a man, aged 26, under Mr. Bowman's care, for whom excision of the astragalus and malleoli had been performed about three years before. The resection operations had been performed by the late Mr. Statham; and had been two in number, the first consisting in the removal of the astragalus, and the second in sawing off the malleoli and gouging the surface of the tibia. Although at first a cure had been hoped, yet the diseased processes had continued in the tibia to such an extent as to prevent any use of the limb. A single sinus remained. When admitted under Mr. Bowman's care, the man wished to have amputation performed, and to this wish Mr. Bowman acceded. On March 26 amputation was performed, Mr.

Teale's method (by rectangular flaps, one short and one long) being adopted. With regard to the amputation we need not say more than that it answered well, and that the man recovered with a good stump. On dissection of the foot the under surface of the tibia was found united to the tarsal bones by firm ligamentous tissue. The astragalus was wholly wanting.

There are of course not a few exceptions to the remark, but we fear that the above case is but too good an example of the usual result after resection of the ankle-joint. For the wrist and ankle, where many bones, and those consisting of porous structure, have to be interfered with, the operation of excision seems but ill-adapted. We have seen some very good results after it, but we have seen still better after treatment by rest and constitutional measures only. The Surgeon's knife and saw, and, above all, his gouge, are but too liable to extend the carious ulceration which they are intended to remove. We have repeatedly seen cases of this class disappoint the Surgeon's hopes after an infinity of care and trouble, and come to amputation at last.

THE PROVINCIAL PRACTICE OF MEDICINE AND SURGERY.

THE HULL INFIRMARY.

EXCISION OF THE KNEE-JOINT—SUBSEQUENT AMPUTATION—DEATH.

(Under the care of Mr. CRAVEN.)

[Reported by Mr. EVANS, House-Surgeon.]

ROBERT C. aged 31, a cachectic-looking man; married; an engine-driver by occupation. Admitted on March 3, with disease of the left knee-joint. He came in with the impression of the necessity for the removal of the limb, and with the wish for it if it were so.

History.—He sustained an injury nearly four years ago, while in his occupation, and subsequently injured the knee a second time. He was in the Infirmary last summer, under the care of Mr. Huntington, for about a month, when Scott's treatment was adopted. There were no sinuses nor open sores at that time. He has since had treatment elsewhere, and his knee has been blistered and cupped, and issues also employed. Has been unable to follow his employment for the last nine months.

Present symptoms.—There is general enlargement of the joint, great pain on striking the sole of the foot; two or three sores above the knee, but not leading to bone, the result of issues. No indications of pulmonary mischief. He was ordered liberal diet, and an opiate every night.

March 12.—There is some inflammation and œdema of the integuments below the knee, and great pain in the part. Cold water dressing to be applied.

R. Mist. salin. effervesc. 4tis horis.

16th.—A consultation was held, and it was considered requisite that relief should be obtained by operation; it was resolved that resection of the joint or amputation of the thigh should be performed, according to the state of parts on examination. A long semicircular incision was made over the front of the joint, the convexity downwards. On reflecting the flap thus made, and the joint being exposed, there was seen pulpy degeneration of the synovial membrane, and ulceration of the cartilages, the bone being exposed and rough in several places. The cartilage which remained was soft and very vascular. The ulceration was of the deep kind. The lower end of the femur was now sawn off to the extent of a full inch or more (a common saw being used at right angles to the shaft), and the sawn surface seemed pretty healthy, scarcely more vascular or softer than natural. The upper end of the tibia was then sawn off in the same manner, to the extent of half-an-inch, and the bone appeared perfectly healthy. The patella presented the same appearances as the rest of the joint, and was removed entire. At this stage of the proceedings a quantity of very fetid pus escaped, appearing to come chiefly from the soft parts below. Two or three vessels only required a ligature, and the wound was closed with iron-wire sutures. Wet lint was applied, and the limb bound down upon a straight splint, with two side ones, and

the part was kept cool by irrigation for the first few days. Half-a-drachm of liq. opii sedat. was given immediately after the operation.

8 p.m.—Has had some sleep and feels comfortable. Pulse 140, tongue moist. The opium is repeated.

17th.—Had a very tolerable night. Pulse 140. Vespere.—Pulse 120.

18th.—Pulse 120, feeble. Not much appetite. Ordered eight ounces of wine daily, and a cinchona draught three times a-day.

20th.—Knee dressed; looking well. No tension or inflammatory appearance about the sutures. Copious discharge from wound.

25th.—An abscess has formed in the calf. Incision made, and free discharge of matter. Ordered a quinine draught three times a-day, and allowed brandy in addition to his wine.

28th.—All the sutures were removed, one or two only having sloughed out. The flap has united by granulation in nearly the whole extent.

April 15.—Wound dressed every two or three days since last report. The thigh has a tendency to rotate outwards. Rather a troublesome cough, with slight mucous expectoration. Ordered ipecacuanha and conium for his cough.

24th.—Can sleep now without his anodyne. The flap of integument over the knee is gradually withdrawing itself from the opposing one, thus exposing a broad semi-circular line of granulations, which are rather soft and flabby. The amount of discharge continues very great. The excoriation from the discharge is greatly relieved by dusting the part with powdered oxide of zinc. Notwithstanding all care, a sore has formed upon the heel.

May 20.—Limb in better position and firmer. General health very fair. Bowels less relaxed, but stools of an unhealthy character. Sleeps well.

27th.—A sore has now formed under the knee, from which there is free discharge. There is no attempt at cicatrisation of the wound made at the time of the operation. There is a collection of matter on the outer side of the thigh, which escapes from an opening near the knee.

June 4.—He remains much the same. There is a tendency to relaxation of the bowels. Leg dressed twice or three times a-week; the discharge continues very abundant, and is thinner and more watery in character.

28th.—The foot has become a good deal inverted, and the least movement of it gives him very great pain at the knee. There appears to be some union of the bones, though not much. Appetite indifferent. The patient expresses an urgent wish to have the limb removed. A consultation was again held, and, all things considered, it was resolved to accede to his request.

29th.—(Three and a-half months after excision.) The patient was brought into the operating theatre under the influence of chloroform. The thigh was amputated in the upper third by the circular method; very little blood was lost. The muscles of the thigh looked dark and unhealthy. No sutures were put in, but the integuments merely brought over the stump by wet lint, and a turn or two of bandage.

R. Liq. opii sed. ʒi xij statim et h. s.

On examining the limb, there was found to be no union of the bones, although they were in apposition, and their surfaces were for the most part covered with soft, pulpy-looking matter.

30th.—He had a fair night. Pulse feeble. Beef-tea, wine, brandy, etc. ad lib.

July 1.—Has vomited once or twice, and does not take much support. Pulse very small and feeble. He evidently will not rally.

2nd.—He died this day about noon.

Remarks.—As the bones were in apposition, and yet union of them did not take place, the failure of it must be attributed to the debilitated and cachectic habit of body which the man possessed; and which the dark, flabby condition of the muscles gave evidence of. It is probable that had amputation been performed in the first instance the man would have recovered; yet at the time of the operation the state of the bones seemed fully to justify the attempt which was made to save the limb.

ELECTION AT THE ACADEMIE DE MÉDECINE.—M. Ambrose Tardieu has been elected into the Section of Hygiene and Legal Medicine, by 62 out of 69 voters present.

THE COLONIAL PRACTICE OF MEDICINE AND SURGERY.

SYDNEY HOSPITAL, NEW SOUTH WALES.

LARGE FIBRO-CELLULAR TUMOUR SITUATED ON NATES.

(Communicated by Mr. ALFRED ROBERTS, Surgeon to the Hospital.)

R. B., aged 29, has always enjoyed good general health, is a native of India, and has been fourteen years in this colony. About twelve years since he received a blow upon left nates, which was followed for some time by a small painless swelling over the seat of injury; this has gradually increased up to the present time, but its progress has been more rapid during the last two or three years. On one occasion he fell from a horse, and struck the tumour upon a stone, by which it was extensively lacerated; the wound, however, healed rapidly. His occupation is that of a shepherd and gardener. He wishes to have the growth removed, which, although painless, is very inconvenient. He appears to possess a sound constitution, a placid temperament, and to be in a good state of health.

Situated over the left nates is a large tumour, pendulous when the patient is in the erect posture, loose and extending at its base. When he lies upon his face it has the feel of a fatty tumour as a whole; but about one-half of the mass is covered by hard tuberculous masses, which apparently pervade the subcutaneous cellular tissue, and to which the skin is firmly adherent; the skin and subcutaneous cellular tissue cannot be raised, or moved upon, more than one-fourth of the morbid growth. Examined, with the patient lying upon his face, the tumour appears to be bounded as follows:—superiorly and externally, it extends on right side to within two and a-half inches of superior and anterior spinous process of ilium; on left side, to within an inch of trochanter major, overlapping and inferiorly occupying, the superior and posterior portion of thigh three inches; on right side it also partially surrounds the sphincter ani, pressing heavily upon the rectum. The circumference of base is thirty-one inches; length of same, twelve inches; breadth, ten inches.

I considered the mass to be steatomatous, but containing an unusual, and very large proportion of dense cellular tissue irregularly distributed; the portion of the base over the sacrum was very adherent to the periosteum, and I anticipated that in all probability the growth sent processes of diseased structure into, and between the neighbouring deep-seated parts.

For these reasons I determined to remove the tumour by an elliptoid incision, saving sufficient covering for the wound from the most healthy portions of the side of the growth, taking away as much of the diseased structure as possible without minute and deep dissection. The patient being placed under the influence of chloroform, the operation was rapidly performed, with scarcely any loss of blood.

The mass removed, weighed upwards of seven pounds, and contained but little healthy fat; it was apparently composed of dense glandular-looking formation, which in some places were of almost cartilaginous hardness; numerous detached glandular-looking masses were found embedded between the fibres of the glutens maxims, some of the more superficial of which were removed, and the flaps brought together. About a thirtieth or twentieth part of the entire morbid deposit was probably left behind, it being hoped that suppuration might so modify it as to check or prevent its further development. The result of this operation was highly satisfactory, sufficient integument was retained to form a covering for the large basic wound, a very small portion of which only sloughed; healthy suppuration and granulation rapidly set in, ending in a quick recovery. When he left the Hospital the cicatrix was healthy, and the portions of morbid tissue which had not been removed, had very much diminished during suppuration, and were very insignificant.

The mass removed appeared to the eye, as above stated, to be composed mainly, and in its most developed parts, of a series of glands connected by loose cellular tissue; but upon tracing one such body, it was found to be a segment of a long, nodulated, and tortuous substance, some of which dissection

showed terminating in blind extremities, while others seemed to have no termination; thus an end of one of these taken at the cut surface of the tumour, could be easily traced into the mass a considerable distance, and again back to the surface. It might be compared in one sense to an entangled mass of nodulated worms. This structure in approaching the skin (to which it was in many places adherent), merged gradually, more or less, into the character of subcutaneous cellular tissue. Microscopic examination proved the greater part of this growth to be of fibro-cellular formation.

The small amount of hæmorrhage during the operation was remarkable; only one vessel of very inconsiderable size required ligature.

VESICAL CALCULUS FORMED UPON A PIECE OF SLATE PENCIL SWALLOWED SIX MONTHS PREVIOUSLY.

(Communicated by Mr. ALFRED ROBERTS.)

T. B., aged 47, admitted into the Hospital, August 9th, 1856, is a sawyer by trade, and resides at Wollongong. Has occasionally drank freely, but has enjoyed good health. Six months ago, while at work, a friend called him to have a glass of spirits, and going into the house for the purpose, he picked up a piece of slate pencil, which by habit he put into his mouth and swallowed with the spirits while engaged in conversation with his companion. He immediately mentioned the circumstance, and was assured by his friend that it did not matter. On the following or second day, when jumping from a piece of timber, he experienced a sudden, sharp, and pricking pain in the right lumbar region, which continued more or less for five weeks (sometimes keeping him in bed for a couple of days, and always preventing him from working), when it ceased, giving place to all the symptoms of vesical calculus in a severe form. Although he firmly adhered to the above account, it appeared so improbable that the pencil should have found its way from the intestine into the bladder, without greater constitutional and local irritation, that I diagnosed a renal calculus passing into the bladder, upon which the large calculus, probably phosphatic, which the sound detected had formed. The man was prepared for lithotomy, which was performed August 18th. The stone was found to be large and very soft, breaking readily between the blades of the forceps. One end having thus come away, I felt to my surprise the cut end of a piece of slate pencil. This I now seized, but it came away from its bed, and I was obliged to remove the calculus piecemeal. The man made a good recovery, and was discharged quite well on September 24th, 1856.

Immediately after the operation, and while he was still partially under the influence of chloroform, I asked him abruptly, what he passed the pencil down his penis for? But he naturally and without hesitation replied that he had swallowed it. I have since written to my friend, Mr. Lambert, who sent me up the case, to make further inquiries as to the truth of his account. He writes me, that he has seen the person (a small farmer and respectable) who was with him at the time, and that he *fully corroborates* his tale.

The piece of pencil is two and a quarter inches long, and of the smooth made kind, called Dutch pencil; it is bluntly pointed at one end, having evidently been used a little after

it had been sharpened; it is quite perfect, each mark of the knife upon it being distinct. The calculus measured from three and a half to four inches, by from one and three quarters to two inches length and width, and is of the fusible or quadruple phosphate variety. The portion saved weighs dry, six drachms, probably three drachms more were lost during the operation. I have left no stone unturned to elucidate the truth in this very interesting case, and can only state that after much hesitation I have arrived at the conclusion, that the pencil was swallowed by mouth, and made its way by inflammation and ulceration into the bladder. What course it took can only be surmised at, but probably it was in some portion of the small intestine at the time he made the jump, the concussion of which threw the foreign body across the intestine, bringing the pointed end opposite the bladder, and pointing as it were to it; but it may be asked, Would the small intestine under the influence of a body

weighing six drachms, suddenly stretch to the length of the pencil—if not, then it most probably became entangled in a fold of mucous membrane, but in this case it must have occurred in the first portion of ilium. These are questions, however, which I presume can only be solved by a post-mortem examination. I enclose half of the pencil, which will subsequently be sent to Guy's Museum.

NOTES AND QUERIES.

He that questioneth much shall learn much.—*Bacon.*

No. 345.—ENGLISH MIDWIVES IN 1602.

My mother, whether by reason she had a little mistaken her time, or that the country thereabouts yielded no better, was necessitated to make use of a midwife whose neck was distorted by some natural or emergent cause, on the one side, as it has been credibly related unto me, so as the very sight of her at first much affrighted my mother, when she saw her come right forward, and get to look over her shoulder; and had there been either a stay of her throes, which now grew strong and quick, or possibility of another midwife, she would upon no terms have admitted of her help. The woman perceiving, was also herself troubled at it, and, whether maliciously or casually I know not, exceedingly bruised my right eye in her assisting at my birth.—*Diary of Sir S. D'Ewes.*

No. 346.—ACCOUCHEMENT OF MADAME DE BOURBON.

"Her labour was so difficult that it was feared it would be necessary to deliver the child by force. The child was, in fact, born dying. To reanimate it, it was placed in linen soaked in spirits of wine. No one knows how, but the spirits took fire. The women all rushed away terrified. The accoucheur, however, assisted well; and the child's life was saved. It is thought he will live." Thus wrote on August 5, 1772, Madame de Defand, of the birth of a child, who in 1804 ended his career in the ditches of Vincennes, as Duc d'Enghien!

No. 347.—A POPULAR REMEDY FOR HERNIA.

The following singular account referring to the ash tree (*Fraxinus Excelsior*) is taken from a book very recently published, called "Our Woodlands, Heaths, and Hedges," by W. S. Coleman:—"This tree has been the object of some curious superstitions, one of which, at least, absurd as it is, is not yet quite obsolete: we allude to the reputed virtue of a split ash-tree in curing ruptured children. The programme of the ceremony by which this supposed power was called into play is as follows:—The stem of a young ash being cleft down the middle, and kept open by wedges, the afflicted child, in a state of nudity, was forced through the opening, the mother standing on one side of the tree and the father on the other. This uncomfortable transit having been twice performed by the astonished and shivering infant, both it and the disrupted tree were respectively swathed up at the same time; and if the wound in the latter healed, and the parts coalesced, as was generally the case, a simultaneous cure was supposed to be effected in the child. It is but a short time ago, that a poor child suffering from the above infirmity was actually subjected to this process somewhere in Warwickshire." H. L. MAYSMOR.

Springfield-lodge, Park-vill. east, Regent's-park.

No. 348.—MURDER OF SIR THOMAS OVERBURY.

From which day (May 19, 1613), for the space of three months and six days, he had several poisons administered unto him in tarts, jellies, physis, and almost in everything he took; so as the stronger his body and constitution were, the more horrible were his torments; having sometimes, upon the taking of only one fascinated potion, threescore stools and vomits, and divers of them mixed with blood. . . . The last poison that was administered unto him was in a glisten, soon after the taking of which he died in horrible torment and agony, upon the 15th September of the same year. The apothecary who administered it was liberally rewarded for his pains, and received twenty pounds, but could not be afterwards heard of. Notwithstanding the giving of these poisons, which had eaten out his entrails within, and caused great boils and sores to break out in his body without, they—intend-

ing to entomb his good name with his miserable carcass—caused it to be bruited about that he died of the French disease, which is commonly gotten by accompanying with evil women, and that the boils and sores on his body produced by that, made his stench after death intolerable."—*Sir S. D'Ewes' Journal.*

[There is something singular in the similarity between the means employed for Sir T. Overbury's destruction, and those resorted to in certain cases of modern date. There can be little doubt from the above description that arsenic was the poison used in this case.—*Ed.*]

No. 349.—CLAY EATERS.

"Humboldt confirms the statement of Gumilla, that the Otomas of South America, during the period of the floods, subsist entirely on a fat and ferruginous clay, of which each man eats daily a pound or more. The well-known botanist and explorer, Martius, informed me that the Indians of the Amazon eat a kind of loam, even when other food is abundant. Molina says the Peruvians frequently eat a sweet smelling clay; and Ehrenberg has analysed the edible clay sold in the markets of Bolivia, which he finds to be a mixture of talc and mica. The inhabitants of Guianamingle clay with their bread; and the negroes in Jamaica are said to eat earth when other food is deficient. According to Labillardière, the inhabitants of New Caledonia appease their hunger with a white friable earth, said by Vanquelin to be composed of magnesia, silica, oxide of iron, and chalk. The same writer asserts that at Java a cake is made of ferruginous clay, which is much sought for by women in their pregnancy. To conclude this list we must add Siam and Kamschatka as countries of clay-eaters."—*Physiology of Common Life.*

No. 350.—CURIOUS OPTICAL PHENOMENON.

M. Babinet has related to the Academy of Sciences details concerning the singular phenomenon which happened in Paris, on the 27th of May last past. Every shadow, it was observed, had a well marked bluish colour. "Ordinarily," said the *spirituel* academician, "this colour of shadows is ascribed to the reflection of the azure of the sky; but such an explanation of the phenomenon could not be admitted on this occasion, because the whole city was covered with a thick fog—the sun at setting looking like an enormous red disc. The light had a very intensely orange-red colour, and the blue coloration of the shadows must be considered as a phenomenon of complimentary vision. Just in a like way the moon always looks blue, when we see her reflected in the water in the streets of Paris. Its colour is in such case complimentary, to the more or less orange-coloured rays, proceeding from the gas-lights."

No. 351.—SURGEONS AND PHYSICIANS 100 YEARS AGO.

The Duchesse de Choiseul gives the following account of the treatment of fracture of the clavicle a hundred years ago. "Yesterday, the Abbé, wishing to show off on horseback, fell from his saddle on his shoulder, and broke his clavicle. The Physicians and the Surgeons assure us that it is the very slightest of fractures, that the danger from it is nothing, that its consequences are without inconvenience, and that the pain is the least that can be for a fracture. His is a simple one. It was remedied immediately, and directly it was arranged all pain at once ceased. After he was 'dressed' and *bled*, he was sent to bed, and has passed a very tranquil night, though he has not slept much. He has no fever, and is indeed so well, that it is thought there will be no necessity to *bleed* him again this evening; notwithstanding that the practice is to bleed extensively in fractures. If all this passes away without fever, it will be very extraordinary; because we are told that fever always comes on on the second or third day. In the meantime the Abbé is very gay, and suffers from nothing but the bandages, which restrain his movements." Surgeon Pevol seems to have treated the case right well, for the Abbé complains of no inconvenience afterwards. About ten days after the accident he writes (being a lady's man and *spirituel*): "I conclude from all these details, that nothing is of greater service for the cure of *ennui* than the breaking of one's collar-bone!"

The physicians of that day were not, however, so happy. "Madame de Pompadour," writes the Duchesse de Choiseul, "has coughed much, and has a strong fever; but we are assured that there is no danger." The Marquise, nevertheless, died phthisical in one month. This was before the days of Laennec.

Medical Times & Gazette.

SATURDAY, JULY 30.

AMENDMENTS ON THE MEDICAL ACT.

A BILL has been introduced by Mr. Whiteside and Lord Naas, and was ordered by the House of Commons to be printed on July 19. It was read a second time last Saturday morning, and was to be considered in committee on Thursday. It is entitled "A Bill to Amend the Medical Act." After reciting that provision is made by "The Medical Act" for the registration of the Medical Profession, that certain disabilities are imposed on members of that Profession who are not registered, and that Licentiates of Medicine and Masters in Surgery of the Universities of the United Kingdom are authorised to be registered under the Medical Act, it is added that no provision is contained therein for the registration of Licentiates in Surgery of such Universities, and proposes to enact, "that the diploma or Licence in Surgery, as heretofore usually granted by any University of the United Kingdom, should be considered a sufficient qualification to practise under the Medical Act, and that every person to whom such diploma or licence has been granted shall be entitled to be registered under the provisions of the recited Act, in like manner, and with the like effect, and subject to the like provisions as are prescribed by the recited Act in respect of the registration of any Master in Surgery of any University in the United Kingdom;" and by Section 2, that the words "or Licentiate in Surgery," shall be added after the words "or Master in Surgery," to the qualifications described in the tenth head of Schedule A of the Medical Act. Various other specific provisions are then inserted, but these it is unnecessary to notice now.

The sole scope of this new Bill is really to create a new class of Practitioners, under the head of *Licentiates in Surgery*. This object it was attempted to accomplish by the Medical Act Amendment Act introduced last session, but the scheme then proved unsuccessful. The Medical Degrees obtained at Oxford and Cambridge are Bachelor of Medicine and Doctor of Medicine; the first being conferred after a study of three years, the latter title after six. What constitutes virtually a Licentiate of Medicine, or Master in Surgery, we do not now profess to say. We understand, however, that a Diploma or Licence in Surgery is given in Ireland to such students who have matriculated in Medicine, and have completed at least one year in Arts. The men thus qualified, it is now proposed, shall have the right and privilege to practise in any part of Her Majesty's dominions.

A petition from the Edinburgh College of Surgeons against this Bill was presented to the House of Commons, on Tuesday, by Mr. Black, and ordered to lie on the table; and Mr. Henry B. Sheridan has given notice of various amendments to be proposed in Committee, which will have the effect, if adopted, of extending the qualification to register and to practise to Licentiates in Midwifery of the Lying-in Hospital

in Dublin. Section 1, if amended, will therefore, in effect, read "That the Diploma or Licence in Surgery, or Midwifery of any University or by the Lying-in Hospital in Dublin shall be considered a sufficient qualification to practise in Surgery or Midwifery."

Not content with this attempt to add another to the list of qualifications entitling the holder to a place on the Medical Register, Lord Robert Cecil gave notice of a motion to admit Licentiates in Dentistry of the College of Surgeons also to the Register. This motion was to have come on on Tuesday night in the House of Commons, but the House was counted out.

These attempts at legislation by isolated sections of the Profession appear to us to be peculiarly objectionable, now that the whole Medical body is united and represented in the Medical Council. It seems extremely improper for any one body, without the concurrence of others, and still more so without their knowledge and full discussion, to attempt to push any measure through Parliament, affecting the interests of the whole Medical body. If it be for the good of the Public and the Profession that the Universities should have the power of granting Licences to practise Surgery, let the power be granted,—but first let us all be convinced that such a change is really desirable. At all events, let the question be fully discussed among ourselves before any single University urge on a measure which once passed may be very difficult to repeal. Then, as to the Licentiates in Dentistry, the feeling in the Profession would be very strong against their admission into the Medical Register. It was a great mistake to admit those Licentiates in Midwifery who have no other Medical qualification: and this admission of Dentists, who are not members of the College, but are only to have a special licence as Dentists, is a still greater mistake.

THE WEEK.

THE recent trials of Watters and Kahn in this country, and that of Vriès mentioned below, seem to show that if persons will only take the pains to put the law in operation, much may be done to stop imposture. The celebrated "Docteur Noir," alias Vriès, entered into an agreement with the Abbé Bocquet, as expressed in the following receipt,—“Received of the Abbé Bocquet the sum of 2000 francs, on account of a sum of 4000 francs, as the covenanted price of the cure of a cancer by which the Abbé is attacked. The second 2000 francs to be paid as soon as the cure is completed. Paris, Dec. 25, 1858—VRIÈS.” The Abbé, who the “Docteur Noir” had thus engaged to cure, was not long in departing this life, and his widow demanded of Vriès the restitution of the 2000 francs paid on account—as, not having satisfied the conditions mentioned in the receipt, he had no right to retain any portion of the money paid upon the faith of such fulfilment. Vriès declined making any restitution, generously, however, foregoing the balance! The tribunal of the Seine has condemned him to make the restitution, and to pay the expenses.

A Mr. Samuel Nunn has been convicted for “having unlawfully, wilfully, and falsely taken and used the name and title of Surgeon, not being duly authorised to take and use the same, against the statute.” The proceedings were taken by the London Medical Association, which has lately so well distinguished itself in the Bennett swindle case. The facts were clearly proved; and Mr. Secker, the magistrate, fined the defendant 40s., and 28s. costs; and also informed him that he must at once remove the description over his door and his window. This is the first conviction which has taken place under the Medical Act; and demonstrates very satisfactorily that the Act is not a mere thing of words, but possesses much virtue and actual power, and may be used thus bene-

ficially in the service of the Profession, and for the good of the public. The fine, it should be observed, was small, because, as Mr. Secker said, this was the first conviction under the new Act. A full report of the case will be found in another column.

The recent movement for strengthening our national defences has brought into prominent notice the present position of the Militia Surgeons. These gentlemen, it will be recollected, receive no regular pay, and are merely remunerated for a short period of the year when their regiments are called out into service; but since the Russian war and the disturbances in India, the Militia regiments have been frequently embodied, and have been called upon to serve even in distant regions. The consequence has been that the Surgeons have been, in many cases, compelled to relinquish their practices in the several localities where they may have been residing, and to accompany their regiments to foreign stations. The hardship thus inflicted upon the Militia Surgeons has been most serious, for these gentlemen have often been obliged to sacrifice a permanent for a temporary position, and have lost a professional connexion which it had cost them many years to form. They, therefore, very reasonably request that they should be placed upon the permanent staff of their respective regiments, and that thus their services should be recognised and remunerated. It is very properly suggested that this important class of practitioners, even in the disembodied state of their regiments, might be employed in many Medical duties of a military nature, such as the examination of recruits for the Army, Navy, Marines, East India forces, and also of prisoners and deserters and in many other similar duties which the present somewhat warlike aspect of affairs may impose upon the Medical Officers of the Army. We hope that the claims of the Militia Surgeons will be duly considered in the proper quarters.

Mr. D. G. Thackeray, a Surgeon, practising at Radford, a suburb of Nottingham, was on the 22nd instant, convicted at the assizes of having caused the death of a woman by *mal praxis*; and was sentenced to twelve months imprisonment. A sentence of this kind is, of necessity, ruin to a Professional man; and, from the report given of the case, we feel bound to say that it is, in our opinion, an extremely unjust and cruel sentence. The woman, it appears, had a very lingering labour with her first child; and Mr. Thackeray attempted to deliver the child by aid of the forceps and failed. Dr. Wilson was eventually called in to attend the woman, who was delivered shortly after his arrival of a stillborn child. She had been in labour from Sunday night to Tuesday night. Upon his arrival Dr. Wilson noticed that a portion of the substance of the wall of the vagina had been lacerated, and it appeared that this must have been caused by the instruments applied by the prisoner. A portion of the wall of the vagina protruded, and this portion appeared to be lifeless. However, Dr. Wilson replaced it, and afterwards treated the lacerated part with chloruret of lime and of soda, in consequence of his perceiving that there was a sloughy discharge. The deceased lived for a short time, and then died of the effects produced by the wound. An attempt was made to show that Mr. Thackeray was intoxicated, but the accusation failed; so that the question came to rest upon the skill of the defendant. It was proved that he had been most attentive and kind to the woman. But it seems to have been shown to the satisfaction of the jury, that the woman's death resulted solely from his improper use of the instruments.

"Medical witnesses for the prosecution admitted on cross-examination that the instruments used by the prisoner are

sometimes properly employed for the purpose for which it was alleged the prisoner had used them, but they were of opinion that if used with ordinary skill and caution such a laceration could not be made, except it were occasioned by some extraordinary and sudden movement of the patient, although some Medical men take the precaution of using padded instruments, and lacerations might sometimes occur in spite of the greatest skill and caution."

Considering that the death did not occur until many days after delivery, and that sloughing of the vagina is a not uncommon occurrence in long-protracted labours; and that death might have followed if no laceration and sloughing had occurred, we can only repeat that we think Mr. Thackeray has been very unjustly punished. We sincerely trust that none of the Medical men concerned in this case gave evidence tending unfairly to bias the jury. In a case of such manifest difficulty, and where it clearly would be impossible to say in how far death resulted simply from the laceration, the defendant ought to have had every benefit of doubt.

The position of the Medical Society, the oldest Medical Society in London, seems to be at present very precarious. It will be remembered that at the last general election, in March, the "*habitués*" of the Council were ejected by a large majority, and a new Council appointed. The result of this movement appeared to be beneficial. The papers read were good; the attendance of members greater. Present difficulties, however, spring out of this general election. There exists a law which provides that no Fellow two months in arrears at the time of the printing of the lists, which is fixed at the latest eight days before the election, is eligible for office. This law, up to the last election, was never enforced. At the last election, however, the discomfited party enforced it; and thus the names of four or five gentlemen who had obtained the majority of the votes were rejected, and a number of their opponents, although the minority, returned. These latter gentlemen, however, after the explanations made at the first ordinary meeting after the election, resigned *en masse*. Whereupon the remaining Council, acting upon another law which authorises them to fill up vacancies between the anniversary elections, re-appointed those gentlemen formerly excluded by the scrutators. The trustees of the real estate, who, by the will of Dr. Lettsom, are neither appointed nor removable by the Society, believing the Council illegally constituted, refused to co-operate or act with it, or to give over to the Treasurer more than a portion of the funds of the Society, being so advised by legal authority. At a session of Council, held May 4, two of these trustees formally protested against the legality of the acts of Council. Subsequently a memorial to the President, also protesting against the course taken, and signed by some fifty Fellows, was sent in. To meet the difficulty the Council summoned a general meeting of the Society, which was held last week. It was clearly proved and admitted by all parties, that the usages and practice of the Society warranted the appointments made, but the whole question hinged upon how far the law upon which the Council acted was or was not controlled by the law above quoted. The oratorical display on both sides was excellent; but the Council was outvoted by 38 against 25. Here matters might have stopped, but that an attempt was made, when most of the members had left the room, to exculpate a former officer of the society under the old *régime*, and whom some Fellows supposed was reflected upon by some ill-chosen words in the financial report. That officer's character stands so high that it would have been folly to assail it, even if desired, which was not in any way shown to be the case. A resolution was carried by which the financial report was withdrawn, and a vote of thanks for past services rendered to that officer by the Society. This vote, although generously moved and seconded by two gentlemen on the Council,

and taken in connexion with the first resolution passed, amounts almost to a vote of censure upon the present Council. This body has not been supported by the independent party in the Society; and the apathy shown in the matter by the majority of Fellows of the Society (only 63 voting out of some 240), may perhaps oblige the Council, in maintenance of its own dignity, to resign *en masse*. If they do, the difficulties will not stop here. The course taken shows to what an extent party feeling exists. Yet there are no laws extant by which a general election can be held, the Society providing only for one general election in March. The Election Committee, which nominates the candidates for office, can only be elected at an ordinary meeting in February. Another, perhaps several, general meetings of the Society must be called—a hazardous proceeding, to say the least, in the state of parties. The present Council cannot reaccept office. If the old *régime* come in again, a large secession of Fellows must be expected; and thus, with diminished receipts, increased expenditure, and perhaps legal expenses to pay, what Council will incur the responsibility? The position should be understood by all, or the oldest Society in London will soon be numbered among the things of the past.

We understand that for some weeks past negotiations have been going forward between the Colleges of Physicians and Surgeons of Edinburgh for the purpose of enabling these bodies, in conformity with Clause XIX. of the Medical Act, to unite or co-operate in conducting the examinations for the qualifications conferred by each. Such an arrangement, of course, requires the sanction of the General Medical Council; but we believe that we are correct in stating that the arrangements between the two contracting parties are now in such a forward state that they will be submitted to the meeting of the Council next week. We understand that the general principle of the arrangement is, that the preliminary examination in literature and science, and also the examinations on those professional subjects which are common to Medicine and Surgery, shall be conducted conjointly by a Board formed of examiners in equal proportions from the two Colleges. The examinations in the practical branches of Medicine and Surgery are to be conducted exclusively by examiners from the College of Physicians, and the examinations in Surgery exclusively by examiners from the College of Surgeons. After passing through the final examinations successfully, the candidate will receive two diplomas, one from each College, so that he may be enabled to register two separate qualifications—"Lic. Roy. Coll. Phys. Ed.," and "Lic. Roy. Coll. Surg. Ed." It were perhaps desirable that some title were allowed to be entered on the register specially to designate persons thus examined, and thus qualified; but the terms of the Medical Act are too precise and definite to allow any other qualifications to be entered on the register than those enumerated in Schedule A to the Act.

Mr. Griffin has laid before the Poor-Law Board the draft of an Act of Parliament on the subject of the remuneration of the Poor-Law Medical Officers. The first section, which defines the class of persons entitled to Medical relief, involves many difficulties, from the fact that there is no uniform system at present of affording relief on the part of the overseers; some granting, and others refusing, orders to the sick poor, according to individual judgment or caprice. The section specially referring to remuneration, is drawn up by Mr. Griffin in accordance with the scheme suggested by Mr. Estcourt, the late President of the Poor-Law Board, except that Mr. Griffin raises the rate of remuneration proposed by that gentleman, from 1s. 6d. to 2s. 6d. per case of sickness. To meet the third indefinite element in Mr. Estcourt's scheme, Mr. Griffin introduces an *acreage* payment for the district

Medical Officers, as one which admits of no doubt or cavil, the number of acres in each parish being already defined; and a *mileage* payment for the Medical Officers of Union Workhouses, although this payment will be applicable to very few persons, as most of the Workhouses are situated within a mile of the residence of the Medical Officers. The payments, at present, of the Union Medical Officers amount to £177,039 4s. 3d. per annum, of which £150,941 3s. 11d. are paid to the district Medical Officers, and £26,098 0s. 4d. to the Medical Officers of Union Houses. The payments proposed in Mr. Griffin's scheme will amount, in the case of the District Medical Officers, to the following sum, viz. for paupers in receipt of relief, on an average taken in January and July, at 1s. 6d. each, £59,345; for each case of illness at 2s. 6d., £136,840, and for acreage, at 1d. per acre, £146,210, making a total of £342,395: and for Union Medical Officers, for paupers in receipt of relief, on an average taken in January and July, £8793; and for each case of illness at 2s. 6d., £33,992, making a total of £42,785; mileage to be added in a few cases. The extra fees at present paid amount to £36,386 6s. 4d. per annum, and it is not probable that there will be much increase under this head. The principal question for consideration will be the amount of money to be paid for each case of sickness attended; and it will probably be necessary to lay down some stringent rules for the guidance of relieving officers, because under a *per case* system of payment, orders would no doubt often be repressed, and the sufferings of the poor might be seriously augmented. By the proposed payments a much larger sum than at present would be expended in Poor-Law Medical relief; and, as it might be necessary to propitiate the Guardians, and avert their opposition, it has been suggested, either that a county-rate should be adopted, if Parliament should be unwilling to defray the expense, or that a part-payment should be continued as at present. It would also be desirable, perhaps, that the amendments on the Vaccination Acts should be introduced into this Bill, although we fear that the amalgamation of the questions of public vaccination with Poor-Law Medical relief might tend to make the practice of vaccination repugnant to the population of the country.

WINDFALL TO MEDICAL CHARITIES.—The Baroness de Sternberg has bequeathed, among a host of other charitable legacies, the following:—To the London Hospital, the Samaritan Society connected therewith, and to the Marine Society, £3000 each. To the Whitehaven Infirmary, £1000 towards forming a fever ward; £300 towards repairing a wing thereto, which was built at her expense; £1000 for a Samaritan Society to the same, and £1000 towards the support of a chaplain to that infirmary; and has bequeathed to the Whitehaven Infirmary the portrait of the late Joseph Steele, her friend and benefactor, with a request that it may be placed in the board-room of that institution. To the Royal Medical Benevolent Fund £1000, and a legacy of £500 to each of the following institutions,—City of London Lying-in Hospital, City-road; Middlesex Hospital (the Cancer Ward); Brompton Consumption Hospital; St. Luke's Hospital; Asylum for Idiots, Redhill; Refuge for the Destitute, Hoxton; Eastern Dispensary, Great Alie-street. The whole of the bequests, whether charitable or otherwise, are to be paid in full, without deducting the legacy duty.

THE STATE OF THE THAMES.—A report from Professor Miller, on the present state of the River Thames, states that, notwithstanding the long drought, in consequence of the use of deodorising agents, the river was not so offensive as it was last year. It also stated that a report had been received from the Surgeon of the Dreadnought hospital-ship, which stated that, although the river was very unpleasant, yet no ill effects had arisen to those on board, either sick or healthy. A report was also referred to from Dr. Guy, the Medical superintendent of Millbank Prison, stating that, although there were 1000 inmates, they had not suffered, in any appreciable degree, from the state of the river.

REVIEWS.

A Treatise on Medical Electricity, Theoretical and Practical.
By J. ALTHAUS, M.D. London: 1859. 8vo. pp. 352.

FOR many years past the application of electricity in the treatment of disease has been conducted by men of such a peculiar scientific stamp that the practice has given rise to ridicule rather than respect, and to opposition rather than favour. It is not until very recently that this important mode of treating diseases has received the attention of men competent to the task; and even these men, with the best intentions as their bases of action, have been obliged to make their attempts as strong men treading a dangerous shore. "I believe every man to be a quack who writes on Medical electricity," said an eminent member of the Profession to us not ten years ago; and we believe that at the time this utterance was made it would have found an echo from almost every mouth. It is certain that such universal expression had a dash of reason to back it. It is equally certain from what we now know of the electric force, that the assertion was unfair, and we had almost said fool-hardy. We arrive at the correct statement of the case by assuming that that which was wanted ten years ago was an improved scientific tone in the writings of authors who treated on electricity and its remedial influences. We wanted a class of men who knew something of the laws of the electrical force; something of physiology; something of pathology; and something of disease. Mere tradesmen, making a machine from a pattern, and then running about with this machine from one sick person to another to administer shocks that would prostrate an elephant, were not the men to advance the science of Medical electricity; but these were the men who then wrote the books and did the business.

We have arrived now at a more fortunate period. The bias formerly existing has been cleared away. Honest labour has swept aside prejudice; and Medical electricity, in its new and improved phase, is becoming a source of interest to all members of our Profession.

For this change of sentiment in this country we are indebted to a few men. We should not be acting fairly did we not award to Dr. Lawrance his due meed of praise as a useful and honest pioneer. We have now the opportunity of paying a further measure of credit to Dr. Althaus, who, in the work in hand, has supplied to the English Profession by far the most elaborate and useful book on the subject upon which it treats extant in our mother tongue. The difficulties which the author had to meet are clearly expressed by him in his preface. We note the whole of his observation on this matter as conveying in very defined sentiment the spirit of the whole book. "Know a preface, know a book" is a critic's common and generally correct axiom.

"That there is at present so little certainty respecting the physiological and therapeutical effects of electricity, is in some measure due to the vast extent of the field that is to be explored, and to the comparatively short time that has elapsed since scientific researches of this kind have been undertaken; also to the intentional falsehoods that have been published, even in the present time, about pretended cures by means of electricity; and especially to the small number of observers who have devoted themselves to the study of these phenomena. We possess a large amount of valuable information and experience concerning the effects of internal remedies upon the system; we know where to procure and how to prepare most drugs; we know how to combine them, and in what cases and in what doses to administer them with advantage. But in respect to electricity we have no such certainty. What form of electricity should be used? in what cases should it be employed? shall we act indiscriminately upon the different tissues, skin, muscles, and nerves, or shall we limit the action of electricity to each one singly? It is easy to understand that we cannot expect beneficial results from the application of electricity, if it is applied by empirical galvanists; if the cases are not well selected; if the apparatus employed does not possess those qualities which are necessary for Medical use; if the dose of electricity given is too large or too small, and if, instead of acting upon the diseased part alone, the whole body or part of the body, is acted upon. If, on the contrary, such mistakes as the above are avoided,

electricity will be found a most valuable therapeutical agent, by means of which many morbid states of the system may be relieved, and even wholly cured.

"It no doubt sometimes happens that in cases which to all appearance are suited for electric treatment, and in which the agent has even been judiciously employed, it nevertheless produces little or no benefit. In fact, electricity is as little infallible as any other remedy we possess. But nobody will doubt the remedial powers of quinine, if it should happen to leave uncured a few cases of ague; and croton-oil will always be reckoned amongst our most efficacious aperients, although it does not invariably relieve constipation.

"There is another important point upon which I feel obliged to dwell: patients are recommended by their Physicians to undergo a course of galvanic treatment in many instances only after every other remedy has been tried without success, and when the disease is of such long standing as to afford but little hope of ultimate recovery. What beneficial results might be obtained in certain affections of the nervous system, if the electric treatment were resorted to in an earlier stage of the complaint, may be conceived from a perusal of the chapter in which the effects of Faradisation in a number of cases of hysterical aphonia are detailed. I shall be especially gratified if I succeed in inducing more frequent recourse to the electric treatment in certain forms of neuralgia, which defy all other therapeutical treatment, and which are wonderfully amenable to electricity.

"Finally, I must allude to the mistake frequently made of employing galvanism alone without any internal remedies. I am quite satisfied that some affections of the nervous system can be cured by electricity alone; but in the majority of cases a simultaneous internal treatment is of the greatest importance, and should not be neglected if we wish to increase the chance of success."

The leading points discussed by Dr. Althaus are as follows:—

1. *Forms of Electricity.*—Under which head are given an epitome of all recent facts relating to the nature of the electrical force, modes of producing electricity, and the substance of what is known regarding animal electricity.

2. *Electro-Physiology.*—In which section is observed the action of electricity in the various organs and structures of the body, including analysis of the experiments of Ritter, Galvani, Humboldt, Marshall Hall, Du Bois Reymond, John Reid, Ziemssen, Richardson, Brown-Séquard, Bernard, the author himself, and various others. We do not, in fact, know any so complete a history of this department of science as the one before us.

3. *Medical Electric Apparatus and its Application.*—This forms the third section, and is equally complete. In this section an important note is made in respect to the volta-electric apparatus fit for Medical use. We quote this entire:—

"A volta-electric apparatus fit for Medical use must furnish two currents, viz. the primary current, or extra-current induced by the action of the spirals of the thick wire upon themselves; and the secondary current, or the current induced in the second wire, which is long and fine. Duchenne has drawn considerable attention to the fact that there is a difference in the physiological action of the extra-current (called by him current of the first order) and of the current induced in the second wire (called by him current of the second order). According to Duchenne the current of the first order acts chiefly on the contractile power of the muscles, while the current of the second order acts chiefly on the sentient nerves; and on the retina when applied by means of moistened conductors to any point of the face or scalp animated by the trigeminal nerve. Duchenne has referred this difference of action to a special elective power in each of the currents, and is borne out in this supposition by M. Bouvier; but I am inclined to adopt the view first put forth by M. Becquerel (a), viz. that the difference in the physiological effects of the two currents is merely due to the difference that exists in their tension. Duchenne's observations are correct, but his explanations are unsatisfactory, as there is no other difference than that which naturally arises from the physical condition of the wires: a current circulating in a short and thick wire possesses less tension than a current circulating in a long and fine wire. Therefore, the extra-current will have a trifling effect on the skin, which offers a great resistance to

(a) *Traité des applications de l'électricité*, etc. Paris, 1857.

the passage of an electric current, and more effect on the contractile power of the muscles, which, in consequence of the large amount of water they contain, are better conductors of electricity; while the current induced in the second wire, which possesses a high tension, will not only powerfully affect the muscles, but also the skin and retina. For the same reason a layer of water is more easily traversed by the current induced in the second wire, than by the extra-current. Messrs. Breton Frères have shown by a simple experiment, in which the arrangement of the wires was modified, that the effect which has been attributed by Duchenne to the current induced in the second wire may be obtained from the extra-current, and *vice versa*. It is, however, important that the same apparatus should furnish both currents, as in some instances a current of very low, and in others of very high, tension is required."

4. *Electricity as a means of Diagnosis* forms the fourth section. It is less complete than some other parts, perhaps, but highly interesting.

5. *Electro-Therapeutics*.—In the fifth section all the practical meaning of the book is embodied; it is, therefore, written with more of detail and illustration.

The book ends with an appendix on atmospheric electricity and lightning.

If we have been sparing in our quotations from Dr. Althaus's work, we have been so from the belief that the book will command general reference. We expect to see it for some time to come the standard English work on Medical electricity. If we have forbore from critical argument, it is because the book is not of argumentative type. It is a book of facts and observations, with as little of theory as can be dreamed of, and as much of information as the printer could compress into the space allowed him.

In closing the book a word is due in regard to its merits as a literary composition. Dr. Althaus, far from Fatherland, writes to us in a tongue new to him, but familiar to us as our own language in its simplest and purest character. Truly some of our Anglo-German authors might, without assumption, teach English composition to many Anglican writers.

Les Climats de Montagne considérés au Point de Vue Médicale.
Par le Docteur H. C. Lombard. Genève, 1858. 8vo, pp. 192.
Seconde Edition, entièrement refondue.

Mountain Climates considered in their Medical Point of View.
By Dr. H. C. Lombard. Geneva: 1858. Second Edition,
entirely remodelled.

OUR readers may remember having met with a notice of the first edition of Dr. Lombard's work on Mountain Climates, in our second volume for 1857. A second and greatly enlarged edition of the book is now before us, conveying much additional and valuable information on a subject which we must confess has been hitherto more or less neglected by the Medical Profession. The efficacy of mountain air in very many diseases is now universally admitted, and proved beyond doubt by the success attending the establishment of sanatoria in high districts, as, for instance, those erected by our government on the Himalaya mountains. We may suggest that a great number of invalids sent to the sea-side to recruit their health after a long illness, or to recover from the fatigue of London business, would derive infinitely more benefit and enjoyment from the romantic scenery of the Highlands or the still more bracing atmosphere of the wild and beautiful Swiss mountains. The present work is written in a correct, easy, and pleasant style, and will be found most useful, not only to the Medical Profession, but also as a travelling companion in the hands of those, who for the sake of their health are in search of a suitable and comfortable residence in a mountain district. The great experience obtained by our author from an extensive Medical practice in the town of Geneva is a warrant of the correctness of the information he imparts in the volume under our consideration.

We observe in Dr. Lombard's book that the climate of a mountain district acts very beneficially on those patients who suffer from disorders of the digestion, care being taken not to overtax the digestive powers by giving way to the temptation created by an increased appetite, of eating more than can be easily digested. In many cases, where the health is affected from a deficiency of the functions of respiration, or in a

t tedious convalescence from a disease which has required an active antiphlogistic treatment, the bracing air of the mountain, full of the fragrant particles of the Alpine fir-trees, will kindle the spark of life into a bright blooming health. The progress of phthisis, when the formation of tubercles has not proceeded beyond a certain point, and when unattended with fever, is not unfrequently checked by a residence on a hill, in a spot carefully sheltered from the cold wind, and exposed to the rays of the sun; this treatment being, however, contra-indicated when the disease is accompanied with fever or a predisposition to hæmorrhage.

The beneficial influence of mountain air is remarkably conspicuous in certain cases of nervous exhaustion from excessive mental exertion, anxiety, and moral depression; the same observation applies to hysteria attended with much muscular weakness. Scrofulous patients will also do well to take up their residence in a mountainous district, choosing a warm place where they can leisurely bask in the sun.

The above remarks show that our author has given due attention to the practical part of his subject. We recommend his book to the Medical Profession, and to all those who are about to set out for an excursion among the Swiss mountains for the sake of health.

PROGRESS OF MEDICAL SCIENCE.

Selections from Foreign Journals.

ON THE ACCIDENTS PRODUCED BY CATHETERISM.

(By M. CHARLES PHILLIPS.)

THESE not unfrequently occur, however carefully and adroitly catheterism may have been performed. Usually, they are not to be predicated, although they are more frequently met with in certain diatheses, and during old chronic affections, which also add much to their gravity and importance. The size of the instrument or nature of the operation do not seem to exert any effect in their production; nor do nervous and pusillanimous subjects seem to be more liable to them; but the seat of the affection appears to have considerable influence, as they much more frequently occur when this is near the neck of the bladder or beyond the bulb. The explanation of the exemption of women from these accidents by the ease with which catheterism is performed on them, seems contradicted by the fact that they sometimes, in men, follow catheterism when performed with the greatest ease, and at others are not produced by the most violent manœuvres.

Passing by those of the accidents which are of a local character, such as hæmorrhage, retention, etc., M. Phillips confines his attention to the *general* accidents, which may be divided into three categories: 1. They are manifested under the form of simple febrile paroxysms, unattended with complications. 2. The febrile accident is complicated by some disease, especially of the urinary organs, and particularly of the kidney. From simple intermittent it becomes a remittent affection, and only temporarily yields to quinine. [In the 3rd, the febrile paroxysms are more or less rapidly followed by the production of phlegmonous inflammations and suppurative arthritides. In the simplest form, the febrile paroxysm much resembles that of ague, except that it is determined by the catheterism, and is less regular in its recurrence. Whether confined to the simple febrile paroxysm complicated with disease of the urinary organs, or accompanied by abscess, the paroxysms may assume the quotidian or double tertian type. The continued remittent type is oftenest met with when there is prior disease or abscess. Under these circumstances, too, the pernicious condition may ensue, or it may at once arise in the aged or enfeebled.]

Simple Febrile Paroxysms.—Sometimes these disappear promptly of their own accord; but at others, they are more persistent, or may even assume the pernicious form. Under all circumstances, however, they yield to the action of quinine.

Febrile Paroxysms complicated with Disease of the Urinary Organs.—When disease of these exists, febrile paroxysms are easily induced, although in the case of their being slight, they may sometimes yield, like the simple ones, to quinine. In other cases the fever is converted into an obstinate continued

remittent. When the disease of the urinary organs is more serious, this type, or the pernicious form of fever, may be at once developed.

Production of Pus in the Joints.—M. Velpeau first described this as one of the accidents supervening upon catheterism. In certain of the patients suffering from disease of the urinary organs, a considerable effusion takes place in one or more of the joints. They rapidly increase in size, and become red, hot, and very painful; and the danger is then very great. The pus which forms is very fluid and very fetid, resembling that of urinary abscess.

Diagnosis and Prognosis.—The really important question to decide is, whether the febrile paroxysm supervening upon catheterism have aroused or revived a nephritis,—of all complications in these cases the one to be most dreaded. Determined in the affirmative, we have then to ascertain how far this complication may have placed the case beyond our aid. If after one or two paroxysms, there being constant renal pain, the skin is found harsh and dry, the pulse rapid and full, and above all if the tongue which is always dry and sometimes cold becomes covered with a blackish coating, the worst issue is to be expected. When the fever is followed by phlegmonous inflammation or arthritis, we may at first confound the disease with an attack of rheumatism, gout, or gonorrhoeal arthritis. The rapid progress of the disease to suppuration helps to elucidate its nature.

Nature of the Disease.—Velpeau advanced the hypothesis that admission of some of the principles of the urine into the blood, owing to defective elimination of these, was the origin of the symptoms witnessed: and the researches of Claude Bernard upon the varying colour of the renal blood seem to confirm this view. The urinary odour of the abscesses, even when remote from the possibility of infiltration, has often been remarked. Phlebitis may also give rise to these accidents; but then either a purulent collection existed already, or the passage of the instrument has given rise to the formation of one, and then the patient dies in consequence of purulent resorption.

Treatment.—Experience has shown that preventive treatment is often quite efficacious, and even when not so, remarkably diminishes the severity of the subsequent attack. It consists in administering quinine for four or five days prior to the catheterism, giving six grains per diem in the young and robust, and double the quantity in the aged and enfeebled. When the intermittent paroxysms are quite simple, expectative treatment usually suffices; but when they persist or assume worse types, large doses of quinine, as fifteen to thirty grains, should be given daily. In the case of disease of the kidney, it must be remembered that the quinine is only a palliative, and that the nephritis calls for our greatest attention.—*Bulletin de Thérapeutique*, tome lv. pp. 203—216.

[Dr. Wolff, in the *Berlin Med. Zeitung*, 1858, No. 42, relates an interesting case, in which the patient was carried off amidst febrile symptoms sixty hours after the introduction of the catheter. Dr. Heyfelder, of St. Petersburg, also reports two cases in the *Deutsche Klinik*, 1857, No. 35, in one of which the patient died in twenty-four, and in the other in forty hours afterwards.]

EXCERPTA MINORA.

Acetate of Lead in Pneumonia.—Dr. Brandes, of Copenhagen, has recently strongly recommended the treatment of certain cases of pneumonia by acetate of lead—not as an exclusive method, however, for other means, as expectation, bleeding, etc. all have their proper indications. Generally, bleeding is to be avoided in enfeebled or anæmic subjects; and in these cases Dr. Brandes gives the acetate, generally uniting it with quinine (aa gr. j. alternis horis), or when the cough is very troublesome, substituting opium for the quinine. In young children it has also been found of advantage, half-a-grain being given as a dose to children from one to eight years of age.—*Presse Belge*, No. 28.

Mastic in Nocturnal Incontinence of Urine.—M. Debout recommends the following formula:—Tears of mastic, ʒviij., simple syrup q.s. to form into 64 pills; or if the child swallows badly, the mass may be divided into 128 pills, or the mastic may be made into an electuary with honey. However this may be, if the child is more than ten years old, it must take the whole quantity in four days, i.e. ʒj. morning and evening, two hours before or after a meal. For younger children the dose is diminished, so as to extend the ʒviij. over six or eight

days. If a cure is not operated by the first batch, a second must be given in the same way, but there is no use in going on further. In more than two-thirds of the cases in which it has been used, the cure has been complete, and that in persons from 18 to 24 years old, who had suffered from the affection from infancy.—*Bull. de Therap.* tom. 57, p. 24.

Skoda's Formula in Scorbutus.—Professor Skoda, of Vienna, employs the following preparation with advantage, associating it also with the other means generally had recourse to: Decoct. of malt with fir sprouts 275, yeast 25, and syrup of orange peel 25 parts; a tablespoonful every two hours.—*Ibid.* p. 25.

Holloway's Pills.—Three Spanish pharmaciens of Valladolid declare the following to be the composition of this quack medicine:—Aloes ʒj., rhubarb gr. xxvi., pepper gr. viij., saffron, sulphate of soda, of each gr. iij. Divide into 144 pills.—*Journal de Chimie*, July, p. 403.

Preparation of Camphor Ointment.—As ordinarily prepared, this keeps badly, altering in consistency. M. van Bartelaer recommends the substitution of simple cerate for lard as an excipient or the employment of the following formula:—Camphor 31, lard 125, and tincture of benzoin 6 parts. Rub the camphor very finely by means of the benzoin; then add the lard, and mix well.—*Ibid.* p. 405.

Tannin in Albuminous Anasarca.—The following are M. Garnier's conclusions:—1. Tannin in the dose of ʒ½ to ʒj. per diem cures anasarca or oedema when passively developed and coinciding with albuminous urine. 2. Its curative action is manifested by the abundant flow of urine, which gradually assumes its normal characters, by transpiration, easy alvine evacuations, recovery of appetite, etc. 3. These signs of its action appear after the second day of its administration. 4. Given in solution in doses of from gr. iij. to gr. viij. at a time, it produces no disturbance of the digestive organs. 5. Its action seems to be primarily exerted on the fluids of the economy, coagulating and plastifying their albuminous principles. Its action on the solids seems to be consecutive, tonic, and astringent.—*Ibid.*, July, p. 445.

GENERAL CORRESPONDENCE.

PHYSICIANS AND DOCTORS.

LETTER FROM MR. HUSSEY.

[To the Editor of the Medical Times and Gazette.]

SIR,—While your correspondents are asking, rather than answering, the question whether Licentiates of the Colleges of Physicians,—admitted to the right “tam docendi quam exercendi scientiam et artem medicam,”—are “Doctors,” be kind enough to allow me to remind them of the case of the Physician at Aberdeen, mentioned in Boswell's “Life of Johnson,” who brought an action against the managers of the Royal Infirmary for publishing his name as a “Doctor of Medicine.”

In the argument drawn by Johnson, he says: “What is implied by the term Doctor is well known. It distinguishes him to whom it is granted as a man who has attained such knowledge of his Profession as qualifies him to instruct others. A Doctor of Laws is a man who can form lawyers by his precepts. A Doctor of Medicine is a man who can teach the art of curing diseases.”

If the Medical Registrar finds a difficulty in following the custom, established by courtesy, of addressing as “Doctors” those Physicians “qui non sunt de corpore Universitatis,” why does he address as “Esquires” all Physicians, Surgeons, Apothecaries and Licentiates indiscriminately, — whether bearing the Queen's commission or not?

I am, &c.

Oxford, July, 1859.

E. L. HUSSEY.

FRENCH AND ENGLISH STUDENTS.

[To the Editor of the Medical Times and Gazette.]

SIR,—The remarks contained in last week's Journal respecting the occasionally strange conduct of French Medical students during operations in the Parisian Hospitals, recalls to

my memory a singular scene actually witnessed at La Charité many years ago, when the narrator was attending that Institution, and which merits record as an excellent illustration of what sometimes occurs among our excitable neighbours.

One day Roux was about to perform lithotomy in the Hospital operating theatre, then quite full, many strangers being present, as likewise his eminent father-in-law Baron Boyer. The favoured spectators admitted within the lower area were, as usually happened on such occasions, crowding round, and poking their heads wherever possible, in order the better to see how the great Surgeon would proceed. Every one was looking attentively; and just as Roux began to make an incision into the perinæum, suddenly projected by an invisible hand, down came a large octavo volume designedly thrown from an upper bench at some other person, but which hit the operator so severely on the cheek that the blow made him stagger, and almost fall prostrate on the floor, unless for the support rendered by those around. Starting up furiously, Roux seized the offending yet innocent book, tore it into pieces, "sacréng and foutreng" in a paroxysm of rage. He next danced upon the scattered fragments, and vehemently demanded who had dared to perpetrate the deed here briefly described. Of course no reply could be heard amid the commotion thus created, and while the uproar continued, which it did for some time, although that is by no means unnatural in French audiences, especially whenever parties are deeply excited. However, tranquillity having been at last restored, the operation was finished with M. Roux's accustomed dexterity, and almost as if nothing untoward had happened to disturb his equanimity. Whether the juvenile delinquent was afterwards found out has escaped the writer's recollection: but the main facts can never be forgotten, and will always constitute one curious reminiscence at least of an English student's life in Paris not long after the battle of Waterloo.

I am, &c.

AN OLD FELLOW.

July 25, 1859.

VITAL CAUSES.

LETTER FROM DR. HEALE.

[To the Editor of the Medical Times and Gazette.]

SIR,—In reference to my treatise on "Vital Causes," which you were good enough to review in your last number, permit me to explain that the salient objects which I had in view were as follows:—

First, I wished to call attention to the fact, that by the combination of oxygen with the blood in the lungs in the act of breathing, a galvanic current is generated, which is conducted by the different circles of blood to all the organs of the body, compelling them to act in unison with each other and with the lungs.

This fact was communicated to the Royal Society, and all the details of numerous very careful experiments, in which Mr. Samuel Lane lent his invaluable assistance, were also given. The paper was only published in abstract; but after having confided the facts and details to the Royal Society, I am precluded from making a republication of them myself. It was contended by some of the Fellows, who were present when my paper was read, that although it was undisputed and indisputable that such a galvanic current could be demonstrated, and that this galvanic current became more powerful or otherwise, precisely in proportion as the vitality of the animal under experiment was increased or diminished, yet the Fellows could not in any degree see how this current could have any influence on the vital operation.

Actual physical demonstration, then, being found of so little moment, it is now my endeavour to show, by pure physiological reasoning, that it is inevitable that there must be such a galvanic current, and that all the vital operations of the body are governed by it, and this is the purport and gist of my work.

My object has also been to apply to physiological reasoning those principles of deduction which Dr. Faraday discovered and demonstrated in reference to inorganic combinations.

My next intention was to bring to the notice of the Profession, certain conclusions which I arrived at after much careful research as to the minute distribution of the blood-vessels in the lungs. A summary of these will be found in my

treatise from page 88 to 104. A paper containing all the details with reference to these investigations, was sent to the Royal Society, but I regret to say this also was only published in abstract—and I am precluded from the same reasons as quoted above from again making use of them. The conclusions, however, are open to the scrutiny of every anatomist in Europe, and my anatomical preparations establish them beyond all controversy.

I am, &c.

JAMES NEWTON HEALE.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 28, 1859.

F. C. SKEY, Esq. President, in the Chair.

A paper by W. ADAMS, Esq., F.R.C.S. was read, on

THE REPARATIVE PROCESS IN HUMAN TENDONS AFTER SUBCUTANEOUS DIVISION FOR THE CURE OF DEFORMITIES,

ILLUSTRATED BY A SERIES OF SPECIMENS AND DRAWINGS FROM FIFTEEN POST-MORTEM EXAMINATIONS.

Specimens of reunited tendons after division were exhibited from ten cases, and also drawings, made by Ford, of the recent appearances in thirteen cases, at periods between four days and three years after the operations. These specimens had been collected by Mr. Adams during the last eight years, and were principally from patients operated upon at the Royal Orthopædic Hospital; but for two specimens he was indebted to Mr. Erichsen and Mr. Curling. After alluding to our at present scanty information on this subject, and describing the recent appearances in fifteen cases, the author gave a general summary of the reparative process, describing—1st. The immediate results of the operation. 2ndly. The commencement and nature of the reparative process. 3rdly. The general appearance and structure of the newly-formed connective tissue, or new tendon. And 4thly. The junction of the new with the old tendon. This was followed by an account of the circumstances which may interfere with the perfection of the reparative process, or entirely prevent it, so that non-union of the divided tendon may result. Complete failure of union had been witnessed by the author only in the posterior tibial tendon, but it appeared that there is considerable risk of such an occurrence whenever tendons are divided in or near to dense tubular sheaths. It was shown that imperfect union might result either from some constitutional defect in the reparative powers of the patient, or from injudicious after-treatment in a variety of ways, but principally from too early and too rapid mechanical extension. The conclusions which the author considered to be established by the above series of cases were arranged under nine different heads. It was stated that tendon is one of the few structures of the body capable of reproduction or regeneration, and that the newly-formed tissue acquires within a few months of its formation the structural characters of the old tendon so perfectly, as that, under the microscope, it is with difficulty distinguishable from it; but it does not acquire through its substance the uniformly opaque, pearly lustre of old tendon; in the mass it retains a greyish translucent appearance, so that the recent section affords an easy method of distinguishing the new from the old tendon. The greatest length of perfectly formed new tendon which the author had seen was two inches and a quarter, and this was in the tendo-Achillis of an adult, a year and a half after it had been divided by Mr. Curling. That the process by which new tendon is formed is essentially similar in animals and in man; that the perfection of the reparative process is in direct proportion to the absence of extravasated blood and inflammatory exudation; and that the sheath of the tendons, when consisting of bone-textured areolar tissue, as in the tendo-Achillis and other tendons surrounded by soft tissues, is of importance—1st. In preserving a connexion between the divided extremities of the tendon. 2ndly. In furnishing the matrix in which the nucleated

blastematos, or proper reparative material, is effused. 3rdly. In giving definition and form to the newly-developed tendinous tissue. That the new tendon always remains as a permanent tissue, and as an integral portion of the tendon, the divided extremities of which it has been formed to reunite. In the specimen exhibited, in which Mr. Adams had divided the tendo-Achillis three years previous to death, an inch and a quarter of new tendon was clearly traceable. The average length of new tendon formed in children to reunite the divided extremities of the tendo-Achillis, Mr. Adams considers to be from half an inch to an inch, and in adults from one to two inches. The author considered the facts adduced in this paper were amply sufficient to disprove the linear-cicatrix theory—the theory at present in vogue, and supported by all his colleagues—which assumes that the newly-formed tendinous structure has a disposition to undergo a process of gradual contraction, such as we see taking place in the cicatrices of the skin after burns, to which it has been compared, and that ultimately it becomes absorbed, the muscular structure at the same time becoming elongated by the force of the contraction of the cicatrix, so as to allow of the re-approximation of the ends of the divided tendon, and the formation of a linear cicatrix. From the present observations it appeared that in the cure of deformities, muscles are elongated by the increased length of their tendons, obtained by means of subcutaneous division, and the development of new tendon formed for the purpose of reuniting the divided extremities of the old tendon. The mechanical and physiological effects of this increased length of the tendons were described; and lastly, the author stated that when recontraction of the foot takes place, and the deformity returns at a distant period after tenotomy, this does not depend upon absorption of the new material, or new tendinous tissue formed previously to unite the divided extremities of the old tendon, but upon structural alterations taking place in the muscular tissue. In three cases of relapsed deformity of the foot examined by the author, the new tendinous tissue formed after the previous operations remained, and could be easily distinguished from the old tendon. These facts were regarded as additional evidence against the linear-cicatrix theory.

A paper by HENRY LEE, Esq., F.R.C.S., was also read,

ON DIFFERENT FORMS OF SYPHILITIC INOCULATION.

The object of this paper was to show that primary syphilis does not always commence in the same way. The "specific pustule," in which all syphilitic diseases were formerly said to originate, is produced by one kind of syphilitic inoculation only, and that form was one which does not give rise to constitutional or secondary symptoms. As nearly all the experiments on syphilisation had been performed so as to produce this pustular variety of the disease, it follows that no fresh constitutional syphilitic disease can be engendered by syphilisation so practised. The kind of syphilitic sore which infects the system commences in a different way, and when not artificially irritated, it gives rise rather to the adhesive than to the suppurative form of inflammation. This form of disease Mr. Lee had shown, in 1856, to be, as a rule, not inoculable upon the person who had it. This view had more recently been confirmed by the researches of French Surgeons. But although not ordinarily inoculable like the suppurating form of the disease, yet it was capable of being rendered inoculable by artificial irritation. The results of the inoculation were, however, then uncertain in their results, producing little local irritation, and capable of being transmitted by successive inoculations a very limited number of times. These observations applied only to inoculations performed upon the individuals who had at the time, or had previously had, infecting sores. The author described one kind of suppurating sore which was surrounded by induration which could not always be distinguished from the induration of the infecting sore. The induration could not, therefore, always be taken as the diagnostic mark of a sore which would infect the patient's system. The character of the secretion, however, gave the information which the induration did not always give. If care were taken to prevent any accidental cause of irritation, the secretion from an infecting sore would soon cease to be purulent, whereas, in the suppurating sore surrounded by induration (the phlegmonoid variety of suppurating sore) the secretion would continue, as in other forms of suppurating sores, puriform to the

last. The number of cases of indurated sores which had been said to have been inoculated by Dr. Sperino and others, led to the conclusion that the two forms of disease now described had not been distinguished from each other. It was now ascertained that the infecting sore could not, as a rule, be inoculated upon the patient having it, whereas the phlegmonoid variety of the suppurating sore was of all kinds the most readily inoculated. When inoculated artificially, it produced a pustule containing well-formed pus within forty-eight hours, and it was occasionally followed by an eruption of a brick-red colour, confined to one part of the body, disappearing spontaneously, and not recurring. This eruption was, therefore, certainly not syphilitic.

The various points in the paper were illustrated by experiments, drawings, and tables of cases.

PARLIAMENTARY INTELLIGENCE.

PUBLIC HEALTH BILL.

This Bill was on the 21st inst. read a second time, and passed through Committee of the House of Lords on the 22nd inst.

MEDICAL ACTS' AMENDMENT BILL.

On the motion for the second reading of this Bill on the 22nd inst.,

Sir E. GROGAN asked the right hon. member for Dublin University to postpone it until Tuesday next. The Bill had only just been delivered, and those persons who were affected by it had had no time properly to consider it.

Mr. WHITESIDE declined, and, after a few words from Mr. CARDWELL and Mr. VANCE,

The House divided,—

For the second reading	115
Against it	14
Majority	101

The Bill was then read a second time.

On the 25th inst. in the House of Commons—

ADULTERATION OF FOOD, ETC., PREVENTION BILL.

This Bill passed through committee *pro forma*, in order that some amendments might be printed.

UNIVERSITY (SCOTLAND) BILL.

This Bill, as amended, was considered and agreed to.

UNIVERSITIES (SCOTLAND) BILL.

This Bill was read a third time and passed.

THE LONDON MEDICAL REGISTRATION ASSOCIATION.

SUCCESSFUL PROSECUTION OF A DENTIST FOR ASSUMING THE TITLE OF "SURGEON."

ON Wednesday, July 20, Dr. Ladd, the honorary secretary of the London Medical Registration Association attended before Mr. Secker at the Lambeth police-court to prosecute an unqualified person, named Samuel Nunn, residing at No. 8, Mount-terrace, Lambeth, for practising and assuming the title of "Surgeon," in contravention of the new Medical Act.

Mr. BOWEN MAX, in opening the proceedings, stated that this information was of great importance, as carrying out the preamble of the new Medical Act, and was instituted by the London Medical Registration Association, an Association which had rendered great service to the public and the Profession in prosecuting and putting to flight the notorious Bennett gang, as well as other infamous impostors. The object of the present proceedings was to carry out that clause in the Medical Act which rendered it a criminal offence for any unqualified Medical Practitioner to assume the title of, or to practise as, Surgeon, etc., for which offence he was liable to a penalty not exceeding £20. The defendant, Mr. Samuel Nunn, is a druggist, carrying on his business at No. 8, Mount-terrace, Lambeth, where it would be shown that he (the defendant) had violated the law, both by assuming the title and also by practising as Surgeon. The defendant had had painted over his door the word "Surgeon," followed by a comma, then his own name, Nunn, followed by "Dentist;" on a large square of glass in the shop-window, "Surgeons'

prescriptions accurately prepared." All these letters were what we should term "giant" letters, with the exception of the "s" and the apostrophe, which followed the word Surgeon; these being so small, he should term them homœopathic. This was done with a view of misleading the public, and making them believe he was qualified to act as a Surgeon, whereas he knew nothing whatever of Surgery.

Dr. THEODORE E. LADD stated that he was Hon. Secretary to the London Medical Registration Association. He had examined the Medical Register, and no such name as Samuel Nunn appeared. (It was here objected that the Medical Register was not evidence in a printed form. Mr. Bowen May drew the magistrate's attention to section 27 of the Act, which laid down that "a copy of the Medical Register for the time being... shall be evidence in all courts, and before all Justices of the Peace, etc.")

Dr. LADD (in continuation) stated that a dentist had no right to prefix the word "Surgeon," unless he was a member of some College of Surgeons. He had seen the writing on the shop front of the defendant: it ran over the shop window, "8, Surgeon," in large letters, followed by a comma; then, "Nunn, Dentist," on shop window; "Surgeon," in conspicuous letters, followed by a very small apostrophe and "s"—and "Prescriptions accurately Prepared;" on the side door a brass plate, "Mr. Nunn, Dentist." He never saw the words, "Surgeons' Prescriptions accurately Prepared" written up anywhere else. The usual mode chemists adopt is to state, "Physicians' Prescriptions accurately Prepared."

JOHN OWENS, carpenter, 24, Pleasant-row, deposed that about two weeks since, he met with an accident, and hurt his arm. He called on Mr. Nunn, seeing the word "Surgeon" over the shop window. He saw the defendant, who said he was Mr. Nunn. He did not say he was a Surgeon. He examined his arm, and made him up a bottle of liniment, which he desired he would rub in. He would not have gone to the defendant if he had known that he was not a qualified Surgeon. He paid one shilling for the liniment and advice.

WILLIAM EDWARD HUMBLE, M.D. Lond., stated that dentists were not entitled to the prefix "Surgeon" unless they were qualified. The defendant had formerly been his assistant. He had no qualification to practise as a Surgeon, nor had he any knowledge of Surgery. Defendant left him about six years ago, at which time he took the chemist's shop.

The SOLICITOR for the defence urged upon the magistrate that his client had carried on his business for some time with the same writing on the shop, and as he was a Surgeon-Dentist, he did not think he had infringed upon the Act of Parliament, and was not therefore liable to the penalties under the Act.

Mr. SECKER said he was of opinion that the defendant had been holding himself out as a Surgeon, and it was quite clear that he had brought himself under the provisions of a very useful Act. He had been, he would not say falsely representing himself, but had untruly been pretending that he was a Surgeon, having his name over the door with the direct title of Surgeon, and passing himself as duly registered, whereas his name was not on the Register previous to the 1st of July; and if he had registered since that time, the onus lay upon him to prove it, which he had not done. Assuming him to be a surgeon-dentist, he could not see how that by operating on a man's arm he would be cured of the toothache. By Section 40 of the Medical Act it is enacted that "Any person who shall wilfully and falsely pretend to be, or take or use the name or title of, a Physician, Surgeon, or any name, title, addition, or description implying that he is registered under this Act, &c., shall, upon a summary conviction for any such offence, pay a sum not exceeding £20." But as the case was the first of the kind that had been proceeded with, and as he presumed it would be the first of such convictions under the Statute, the circumstances were likely to create an unenviable notoriety, he should therefore convict the defendant in the mitigated penalty of 40s., with the costs. At the same time he would advise the defendant to take down the writing from his shop, and not mislead the public; for if brought again before him, as the defendant probably would be if he continued using the same words, he would find that he would not be dealt with so leniently.

MEDICAL NEWS.

ROYAL COLLEGE OF PHYSICIANS.—The following Fellows of the College were elected Censors at the last quarterly Comitia Majora:—

BALY, WILLIAM, M.D. Queen Anne-street.
BARKER, THOMAS ALFRED, M.D. Grosvenor-street.
GULL, WILLIAM WITHEY, M.D. Finsbury-square.
WEBER, FREDERICK, M.D. Green-street, Grosvenor-square.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in Classics and Mathematics on Tuesday and Wednesday, the 19th and 20th inst.

ANDERSON, WILLIAM, jun. Lovaine-crescent.
ANSTAY, A. T. Tiverton.
ARGLES, FRANK, Maidstone.
ARMITAGE, FREDERICK WILLIAM, Finsbury-square.
ASHTON, JOHN H. Upper Barnsbury-street.
BADDELEY, WILLIAM BRATTON, Queen's College, Birmingham.
BAKER, GEORGE BENSON, Blackpool.
BALL, JOHN AUGUSTUS, Shadbrooke.
BARROW, THOMAS SAMUEL, Cobden-villa, Whitehead-grove.
BECKER, J. LEIGH, Accrington.
BIRT, JOSEPH, Leamington.
BLOGG, GEORGE, Ipswich, Suffolk.
BLYTHMAN, CLEMENT, Swinton, York.
BOND, THOMAS, Southampton.
BOULT, EDMUND FARRINGTON, Bath.
BROWN, FREDERICK GORDON, St. Mary Axe.
BURNHAM, EDW. ASPWELL, Adelaide-square, Bedford.
CARTER, RICHARD, Newbury.
CLOTHIER, HENRY, Haslemere, Surrey.
COLLETT, FREDERICK, Worthing, Sussex.
CORNISH, GEORGE BISHOP, Taunton.
COVEY, GEORGE, Basingstoke.
CURRIE, JOHN LEGGE, Bungay, Suffolk.
DALGLEISH, JONATHAN, Newcastle.
DAVIES, RICHARD W. Charles-street, Manchester-square.
DENTON, THOMAS JOHN, Bridlington.
EDDOWES, ARTHUR, Loughborough.
EVANS, EVAN, Llandysal, South Wales.
EVANS, EDWARD CHARLES, Cardiff, South Wales.
FALL, JOSEPH, Micklegate, York.
FLOWER, FREDERICK ISAAC, Codford, St. Peter's.
FOTHERGILL, THOMAS PRINCE, Bedale.
FREEMAN, ROBERT GEORGE, Trafalgar-road.
GREUCCOCK, GEORGE, Falkingham.
HALL, ELI, jun. Spilsby.
HALLET, THOMAS G. P. Langport, Somersetshire.
HANKS, WILLIAM, Smith.
HAWARD, JOHN WARRINGTON, Leicester-square.
HAWTHORN, FREDERICK JOHN, Uttoxeter.
HAXWORTH, WALTER, Leeds.
HINDLE, FREDERICK THOS., Asperne-hill.
HOCKEN, CHARLES EDWARD, Rougemont, Exeter.
HOLMAN, HERMAN B. Crediton.
HOWELL, LLEWELLYN, London.
HUEL, CHARLES WILLIAM, Barnstaple.
IRELAND, JOHN ROAF, Kings Swinford, Stafford.
JACKSON, STEPHEN, Bucklesham.
JACKSON, HENRY GILBERT, Leeds.
JAGOE, ROBERT BROWN, Liskeard.
JOHNSON, THOMAS MASON, Great Ousebourne.
KENYSON, GEORGE ARTHUR, Hooton Pagnel, Doncaster.
KING, JOHN.
KELLY, CHARLES, Market Dressing, Lincolnshire.
KNAPP, WILLIAM FREDERICK, Headington-hill, Oxford.
LAKE, GEORGE ROBERT, London.
LAMB, BARNABAS WALTER, Stourport.
LANGFORD, JOHN WHITTON, Ellesmere.
LEE, WILLIAM, Victoria-terrace, Bideford.
LEIGH, FRANK, Regent's-park, Exeter.
LETHBRIDGE, CHARLES FREDERICK, Kennington.
LIBBEY, HENRY CORNELIUS, Manor-row, Bradford.
LISTER, ALLEN LINDSAY, Doncaster.
LLOYD, NATHANIEL H. Tiverton, Devon.
LLOYD, RIDGEWAY RT. The Folley, Radford-rd. near Coventry.
LOWNDES, JAMES MATTHEW, Barnstaple, Devon.
LOWNE, BENJAMIN T. Bartlett's-buildings.
MALIM, GEORGE WARCEP, Grantham.
MORRIS, HENRY, Petworth, Sussex.
OLIVEY, EDWARD, North Curry.
ORTON, GEORGE HUNT, Naborough.
PITT, CHARLES WIGHTWICK, Malinesbury, Wilts.
PURVIS, JOHN PRIOR, Blackheath.
RIX, RICHARD AVERY, Beccles, Suffolk.
ROGERS, HENRY, Bucks.
ROUTH, SAMUEL, Bride House, Chesterfield.
ROPER, ROBERT GEAR, Goswell-street.
SCANNELL, HENRY, 23, Chapel-street.
SHORLAND, EDWARD P. Westbury, Wilts.
SMITH, WILLIAM HENRY F. Romford.
SMITH, FREDERICK, Ruby-grove, Grimsby.
SNELL, EDNEZER, Plymouth.
STEWART, JOSEPH SEPTIMIUS, Tye-hill, Newcastle-on-Tyne.
TAYLOR, THEODORE THOMAS, Cricklade.
TOMLINSON, DANIEL WEBSTER, Erbstock.
TREVES, WILLIAM KNIGHT, Doychester.
TURNER, JOHN SIDNEY, Seaford, Su sex.
TURNER, RICHARD, King's College

WISE, WILLIAM FOSTER, Spalding, Lincoln.
 WEARNE, VIVIAN, Helstone.
 WHIPPLE, CONNELL, Plymouth.
 WILSON, HENRY, Ulverstone, Lancashire.
 WILLIAMS, EDWARD, North Wales.
 WOODCOCK, JOHN RASTON, Ramsbottom.
 WOODRUFFE, DANIEL, Jun., Ipswich, Suffolk.
 WRAITH, JOHN HARGREAVES, Over Darwen.

The following are the names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, July 21:—

DAY, WILLIAM WHITE, Acton-vale, Clifton.
 FISHER, FREDERIC.
 PAYNE, CHARLES WILLIAM, Hoxne, Suffolk.
 RHOBY, JAMES MORRIS, Chorley, Lancashire.
 TUCK, BUCKMASTER JOSEPH.

The following gentlemen also on the same day passed their first examination:—

GATTON, JOHN H., Brixton-rise.
 GREENHILL, JOSEPH RIDGE, Lewes, Sussex.
 HAWTHORN, HENRY JOHN, Uttoxeter, Stafford.
 JONES, THOMAS, Brecon, South Wales.
 MEADE, HENRY, Bradford, Yorkshire.
 ROGERS, FREDERICK JOHN, Helston, Cornwall.
 SPAUNGER, FREDERICK CHARLES, Gainsborough, Lincolnshire.
 WELCH, FRANCIS HENRY, Stansted, Essex.

APPOINTMENT.

The Queen has been pleased to appoint James William Cusack, Esq. M.D. Fellow of the Royal College of Surgeons of Ireland, to be Surgeon, in Ireland, in Ordinary to her Majesty.

DEATHS.

ISAACSON.—On the 24th inst. at Huntingdon, suddenly, of disease of the heart, Wotton Isaacson, aged 45.

SPRY.—On the 14th inst. at his residence in Truro, Edward John Spry, M.R.C.S., L.S.A., Senior Surgeon to the Royal Cornwall Infirmary, aged 59.

STAFFORD.—On the 20th inst. at Long Bennington, Lincolnshire, William Stafford, aged 52.

VIMQUERRA.—Dr. Vimiquerra has just died, at the age of 85. He made the Russian Campaign under Napoleon; afterwards he went through the Spanish Expedition; and then served in Africa. He was at last made Physician of the Military Hospital of Bastia.

A NEW General Hospital and Dispensary has just been opened in Bridge-street, Manchester, at a cost of £1000.

SEVERAL persons at Darlington, we are informed, narrowly escaped poisoning from the effects of putrid cheese, which they had partaken of.

LOUIS NAPOLEON, in returning from Villafranca, passed through Milan. He then visited the Hospitals, and distributed his Legion of Honour not only to the wounded, but also to several of the Doctors and one of the priests.

LORD CANNING has appointed a committee, consisting of General Birch, Colonel Steward, and Colonel Mackenzie, to investigate the present system of a double staff in India in the Medical department, and suggests a prompt remedy.

CHOLERA IN BOMBAY.—Between the 2nd and 22nd June 683 persons, of whom six were Europeans, fell victims to cholera in Bombay; and at the departure of the last mail this fatal scourge raged with great violence.

It has been widely circulated that an epidemic reigns at Arcachon (to which many English now resort as a bathing quarter). Dr. Hameau asserts that the report is utterly false, and that the sanitary condition of the place is most satisfactory.

QUEEN'S UNIVERSITY IN IRELAND.—At a meeting of the Senate of the Queen's University, held on the 18th inst., the following gentlemen were elected examiners for the ensuing year:—Chemistry—William Barker, M.D. Anatomy and Physiology—Benjamin George M'Dowell, M.D. Zoology and Botany—William H. Harvey, M.D. Medicine—Samuel Gordon, M.A., M.B. Surgery—William Colles, M.B. Materia Medica, Pharmacy, and Medical Jurisprudence—R. Macnamara, F.R.C.S. Midwifery and Diseases of Women and Children—F. Churchill, M.D.

LONDON is not the only town suffering from a stinking river. The inhabitants of Hadlow cry out against the Bourne, "which poisons the atmosphere for a quarter of a mile on each side of the stream." St. George's Basin, Liverpool, also, has been "presented" by the grand jury. "Its pestilential state is worse than anything ever complained of from either the Thames or the Clyde."

An Autopsy on the body of the late King of Sweden was held at Stockholm on the 12th inst., in the presence of the Ministers of State and the High Officers of the Court. A report was drawn up, stating that the death of the King arose from general debility, effusion of blood on the brain, and inaction of the heart.

CIVIL LIST PENSIONS.—The following pensions among others have been granted this year:—James Bowman Lindsay, in consideration of his scientific attainments, £100; Mrs. Amelia Gresley Ball, in consideration of the services of her husband, the late Dr. Ball, the naturalist (in trust to Thomas Hutton, Esq., and Dr. Aquila Smith), £400.

PRESENTATION OF A GOLD CHRONOMETER TO DR. LADD, OF LAMBETH.—On Tuesday, July 26, at the Masonic-hall, Fetter-lane, a number of gentlemen assembled, and presented to Dr. Theodore E. Ladd, "as a token of fraternal affection, and in grateful recognition of his valuable and unwearied exertions in the cause of Royal Arch Masonry, July 26, 1859," a gold chronometer, value 50 guineas.

WE are glad to hear that Mr. Henry Sterry, Surgeon, has been the first to erect a public drinking-fountain on the South side of the Thames. He has presented it to the parish of Bermondsey, and the Southwark Company furnish a constant gratuitous supply of good water. It is cheering to see our brethren leading in a movement so obviously beneficial to the working classes.

FLESH AND FOWL.—It appears that it has been the custom of a poulterer in the neighbourhood of Paris to feed his fowls on meat in a state of putrefaction. The Council of Health has lately investigated the subject, through their officer, Dr. Duchesne, with a view of ascertaining, whether animals thus reared are injurious to the health of those who eat them. The result of the inquiry has been, that the poulterer in question has been forbidden to feed his winged animals on flesh. The food does not appear to injure the health of the animals themselves; and their eggs appear perfectly good, only the shell of them is very thin. The flesh, however, of fowls thus fed, is softer than natural, and readily undergoes putrefaction.

CONCEALED BIRTH AND INFANTICIDE.—Notwithstanding all the preparations which had been made, the hippopotamus, which was born a few days back, died on Friday night. The birth took place in the water. The female by her movements signified a desire to go into the basin, and the moment the door was opened she plunged in, and immediately afterwards she was delivered under water, and the little one instantly came to the surface and began to swim about. On the former occasion the female hippopotamus repulsed her offspring, would never let it suck or come near her, and in pushing it away violently, inflicted a wound which caused its death. This time everything appeared to be going on more favourably. The mother gave nourishment to the young one, and allowed it to lie on her back and neck, according to the habit of those aquatic animals. She also remained constantly in the water, instead of as usual frequently leaving it. For a space of about forty-three hours the two animals never quitted the water. The day before yesterday the little one began to walk in and out of the basin. It fed well, and was visibly growing. During the night, however, the mother was seized with a sudden fit of rage and attacked it. "It is an extraordinary fact," says M. I. G. St. Hilaire, "that the females of those mammiferous animals abandon their young, ill-treat, and even devour them. But it is almost without example that when the mother has adopted the young one and given it suck, it should do so. It is true, however, that there is no animal more irascible and brutal than the hippopotamus." The event having occurred under water and in the night, the keeper was not able to give a very full account of what took place, but the results are but too clear. The mother must have seized the young one by the stomach in her formidable jaws, as five deep marks of her

teeth are visible, and she must also have attacked it with her tusk, which pierced the left breast into the lungs.—*Galignani.*

LADIES' ASSOCIATION FOR THE DIFFUSION OF SANITARY KNOWLEDGE.—This association was formed recently by a few ladies, who believed that in the majority of cases the principal cause of a low physical condition was ignorance of the laws of health. They, therefore, combined to propagate the above important branch of education. The first annual meeting was held on the 21st inst. at Willis's Rooms, the room being crowded with ladies. The Earl of Shaftesbury was in the chair. He said none but women could carry out this great work. Among the numbers of institutions that he was interested in, none gave him so much hope as this small one. He then mentioned the disorders of children and what was proper for their management and education. He was certain that if the few things to which he alluded were watched it would prevent many disorders among children. One hundred thousand deaths had occurred during the year from preventable diseases. The association would prevent a great many of these deaths. He considered mothers' meetings of great importance. He knew of nothing that had been productive of so much good. The Rev. Charles Kingsley then addressed the meeting at some length on behalf of the cause of sanitary reform. He dwelt pathetically on the sad amount of infant mortality which prevailed in England, and expressed his conviction that the finest race of men in Europe ought not to be so wastefully allowed to perish. Mr. Monckton Milnes, who followed, spoke of the illustrious example afforded during the Crimean war by those women who came forward with Miss Nightingale to give an impulse to sanitary reform for our army. He expected results not less beneficial from the ladies who had engaged in this work at home. The Rev. J. Rowsell then moved, and Mr. F. O. Ward seconded, a resolution declaring "That a great part of the premature mortality and disease in this country results from ignorance of the laws of health, and that the efforts of the Ladies' Sanitary Association are deserving of the greatest encouragement." This resolution was adopted; and, after some remarks from Dr. Southwood Smith and Dr. Lankester, the proceedings ended with a vote of thanks to the chairman.

DR. BLACKWELL.—A Correspondent of the *Clinique Européenne* writes thus of this lady:—"Most of your readers already know the name of a doctress, of American importation, Miss E. Blackwell, who for some time was a shining-star among us. At the present moment this female Doctor has great success in London. We have in her the most characteristic personification of Medical bloomerism, of therapeutics in crinoline. Miss Blackwell commenced her studies in Paris and London. She then received the Doctorate in an American College, and New York became the theatre of her practice. She there founded a College for the education of ladies. The impulse given by this innovator was so strong, that at the present moment 200 fair Yankees have resolutely set to work in opposition to men, who have hitherto been exclusively engaged in the practice of medicine. Not contented with her first successes, Miss Blackwell has quitted the New World in order to gratify the Old World with a taste of the blessings she has bestowed upon America. Towards the end of last month, the celebrated Doctress commenced her course of Lectures. In her first lecture, she declared, in terms full of enthusiasm, 'That the true vocation of woman is to heal the sick, or at all events to relieve the suffering; that up to the present time man had usurped the monopoly of this vocation; but that it could no longer be borne that woman should be thus outrageously dispossessed of her natural attributes.' In a firm voice she called upon women to retake what had been so unjustly taken from them. Her discourse was received with enthusiasm."

METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer	29.756 in.
Mean temperature	69.0
Highest point of thermometer	93.0
Lowest point of thermometer	56.7
Mean dew-point temperature	59.4
General direction of wind	S.W.
Whole amount of rain in the week	2.15
Amount of horizontal movement of air in the week	360 miles.

TO CORRESPONDENTS.

We are compelled to defer our notice of the meeting of the British Medical Association at Liverpool until next week.

Horsham.—Occasionally, but, we believe, not frequently.

Mr. Pullin.—The correspondence shall receive the necessary attention.

M.R.C.S.—We cannot say if there will be Local Registers published for Scotland and Ireland.

Dr. Willoughby Arding informs us that he finds the diluted unguentum hydrargyri nitratis a very useful application to cancerous sores.

Mr. Avery.—In 1801 there were in England and Wales 1,579,923 inhabited houses; 1,896,723 houses, and 8,892,536 persons. In 1851 the inhabited houses had increased to 3,278,039; families to 3,712,290; and persons to 17,927,609. In 1801, 4½ persons occupied each house; in 1851 the number of persons occupying each house had increased to upwards of 5.

MR. TODD'S INHALER.

Dr. Kidd has sent us a long letter of five pages in reply to the notes of Mr. Todd and Mr. Ferguson, published last week. But the only portion of the letter directly referring to the point at issue is the following paragraph:—

"I wish further to repeat the substance of my former note, as to my inhaler being almost exactly similar to that figured in your journal of the 9th. I have altered mine four or five times since Mr. Ferguson saw it;

there is still the same mouthpiece, and cylinder, and valves; the cylinder in mine is perforated at the top and capable of being opened at the sides to any extent. The cylinder in the new instrument is shut at the top, that seems the chief difference, but opens at the sides; a piston holds a flat sponge, but in mine I have altered the sponge since Mr. Ferguson put it in."

THE PUFF TESTIMONIAL.

The following advertisement, which has been going the round of the Irish newspapers, has been sent to us with an intimation that Dr. Gore belongs to the College of Surgeons of Ireland, and is a resident magistrate in Limerick. If his name is being used without his authority, he should certainly disclaim the testimonial:—

"Doctor Gore presents his compliments to Mr. Solomons, and begs to thank him for the highly satisfactory manner in which he has adapted Cataract Glasses to Mrs. Hogan, Mrs. Jones, and Edmund Naughton, who had been operated upon for Cataract blindness. In these cases the operation rendered the eyes free from disease and restored vision as completely as was in the power of an operation to effect. The right application of an artificial lens was alone wanting to restore the altered optical relationships of the Eye, and to complete the success attendant upon these operations. Dr. Gore feels great pleasure in being able to say Mr. Solomons has effected that so perfectly that nothing remains to be desired. 79, George's-street, Limerick.—To Mr. E. Solomons, Optician to the Royal Family, 19, Nassau-street (within one door of Dawson-street), Dublin, and 27, Old Bond-street, London."

AIR-PLUGS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As I am held responsible for the correctness of the reports of the proceedings of the Edinburgh Obstetrical Society, I beg to observe that the statements contained in the note signed "Albert Monastier, M.D." and published in your last number, are contrary to fact. Had Dr. Monastier been a member of the Society, he would have seen from the "Billets" issued by me, and dated 9th March and 11th May, that on each of these occasions Dr. Keiller communicated to the Society a paper on the subject referred to. The report of the proceedings, as published in the Edinburgh Medical Journal for the present month, has reference to the first of these dates. I am, &c.

JAMES A. SNEY, M.D.
Secretary to the Edinburgh Obstetrical Society.

42, Queen-street, Edinburgh, July 25, 1859.

HUNTER'S STATUE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—To a certain extent I am glad to see so bold a subscription to the above object, although I have added nothing thereto, since I had fancied that Hunter's name could not be more immortalised by the marble than it has already been in our minds and would be in those to come after us.

Be this as it may, I would with caution and modesty suggest to the committee, that if there be any surplus fund, they might see fit to present it to a fellow-committee of the Royal Medical Benevolent College, Epsom, who would be able to apply it to the additional buildings required in order to extend the great object of its noble-minded founder. Accommodation is there required for an increased number of pensioners as well as foundation scholars, as witness the numbers of rejected decayed candidates and sobbing mothers after their disappointment at the last May election.

In this case, I for one (and no doubt many others) would contribute to the Hunter Fund, although like me they may be doing their utmost to support the College, as subscribers, honorary secretaries, or by sending their sons as exhibitors. And thus a sum might be raised to enable the building committee to add a wing or department to the present edifice, which they would be too happy to designate the Hunter Memorial.

I am, &c.

FRED. MANBY.

July 26, 1859.

THE TITLE OF DOCTOR.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I venture to trespass on your valuable space, because it appears to me that many of those who have written letters on the subject, have gone very far from the real question at issue. That the Licentiates of a British College of Physicians have hitherto ranked as high in the estimation both of the public and the Profession, as Graduates of a University, is at once admitted, and the restrictions which have hitherto been attached to the College Licence, has caused it to be held almost exclusively by eminent members of the Profession; that they should, therefore, receive the title of Doctor by courtesy, was a matter of no moment; but when the Edinburgh College of Physicians chose to license anybody who could raise £25, and virtually there was no restriction whatever, the case became different, and those who had spent an extra year in study, and passed the by no means slight examination of the University of Edinburgh, might with reason complain that they were to be deprived of all the honour they had fairly purchased with time and study, by this wholesale production of self-called Edinburgh Doctors by purchase. It is not fair to argue upon the strength of the former distinguished character of these Colleges. In the year 1859, one of them has chosen to grant Licences without the slightest practical guarantee of fitness; and the new Licentiates must be content to have their case argued on their present and unique condition, not on the merits of their College's former status, and the present status of sister Colleges. I am, &c.

Southampton, July 25, 1859.

REGISTRATION INJUSTICE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—If there is one thing more than another from which I am disposed to shrink, it is from that of obtruding before my Professional brethren, or any other body of men, anything personal to myself; but I feel that I should be wanting in a sense of justice to myself, and of regard for the esteem of the members of my Profession, if I allowed to pass unnoticed a wrong which has been done me by the Registrar appointed under the new Medical Act.

Before the 1st of May, nearly three months before the publication of the Register, within the period advertised by the Registrar as entitling applicants to be included in the first registration, I made my application in the form supplied by the appointed officer; and as directed by the Act of Parliament.

My claims were founded on my diploma from the Royal College of Surgeons, London, on which I had extensively practised as a pure Surgeon for twelve years in this country; and on my degree of M.D. from the University of Pisa, which I had received after four years' residence and attendance on the University courses, and after a public examination by the Professors of the University, before a large audience. On this degree I have practised in Torquay since my return to England in 1848.

In making my claims I filled up the forms sent me by the Registrar; and, to substantiate my statement that my Medical degree was received after public examination, I forwarded to the office my diploma from Pisa, which explicitly and fully expresses this fact. I had thus done everything required by the Medical Act to entitle me to the first registration, and had complied with all the requirements sent me by the Council. I was, therefore, perfectly justified in expecting that my name and qualifications would be included in the first Medical Register. I had no intimation of any doubt on the subject, or of any delay, until, in answer to my inquiries, I was informed by the clerk of the office, after the Register was published, that my Medical degree had not been inserted because the Council had received no return from the University stating that it had been granted after examination—a fact fully stated in the only document they had required of me—a printed document, authenticated by the seal and signatures of the University authorities.

Now, sir, I do not in the least question the right or the propriety of any investigations which the Registrar, or the Council, may think fit to make in order to satisfy themselves of the justice of any claims brought before them; but surely, when an applicant has complied with all the requirements of the Act of Parliament, and has produced all the documents necessary to substantiate his claims, the Council cannot consider it right to inflict upon that applicant the punishment of suspending his registration, and subjecting him to all consequent penalties, merely because the Registrar may have delayed the application for some corroborative testimony, or have sent for it to a country involved in revolution, or at a season when a University may be closed.

The new Medical Act expressly states that every person possessed of one or more of the qualifications described in Schedule A "shall be entitled to be registered on producing to the Registrar the document conferring or evidencing the qualification or qualifications whereof he seeks to be so registered." I am aware that the documents produced must be to the satisfaction of the Council, but this clearly must be a reasonable satisfaction, and whilst any "false or fraudulent representation" is punishable by imprisonment, no right is either expressed or implied in the Act by which a legally qualified applicant, who has complied with all its conditions can be deprived of his claim to be registered, or placed in a false position on the register, or suspended for several months from registration, on account of some fault or delay of the Registrar, or of the authorities to whom application may have been made to authenticate the documents produced. Such, obviously, would be to assume a penal power beyond the powers of the Act, and to make the applicant suffer for the delinquency of the Registrar, or the carelessness of the officer of some unconnected and uninterested institution.

But the object of this letter, sir, is not so much to point out the inequitable, and what appears to me, the illegal course adopted at the registration office, as to explain to my professional brethren that the false position in which I am placed on the Register does not arise from any fault or disqualification of mine, but from the provisions of the Medical Act having been in my case wrongly suspended.

Torquay, July 23, 1859.

I am, &c.

C. B. NANKIVELL.

5. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

ADDITIONAL TESTIMONY ON THE EXTRAORDINARY EFFICACY OF DR. J. COLLIS BROWNE'S

(M.R.C.S.L., Ex-ARMY MEDICAL STAFF)

C H L O R O D Y N E.

(Entered at Stationers' Hall.)

MEDICAL PROPERTIES—Anodyne, Diaphoretic, Sedative, Astringent, Antispasmodic, Diuretic.

From W. R. DAWES, Esq.,
Haddenham.

DEAR SIR,—You should have heard from me sooner respecting the effects of Dr. J. Collis Browne's Chlorodyne, but the fact is, that I have found it so universally applicable as a sedative, that there is great difficulty in making a selection of cases which most strikingly mark its beneficial action without rendering my report inconveniently prolix. I can, however, most truly say, that it is a remedy more generally efficient than any other with which I am acquainted. Its sedative and anodyne effects are not only more speedily produced, but they are also more lasting, and are not followed by exhaustion, or headache, or disturbance of the digestive functions; on the contrary, in many instances its continued use has been followed by exhilaration of spirits and improvement of appetite, especially in the various painful symptoms attending uterine irritation. In hysteria and in dysmenorrhœa, this remedy acts like a charm, as also in nervous headaches and in many cases of cough. In fevers, combined in the early stage with tartarised antimony, it is often of signal service; nor is an increase of dose usually requisite to maintain its beneficial action. In a case of phthisis, the moderate dose of ten minims, taken every night, has sufficed for many months to secure quiet rest, scarcely disturbed by cough, while the omission of it is invariably followed by a restless and coughing night. One fact strikes me as very remarkable—namely, that while the tendency of Chlorodyne to produce constipation is so slight as rarely to require an aperient, it has never failed speedily to stop diarrhoea, or to extinguish attacks of ordinary Cholera. In only two or three instances has it disagreed. The sleep which follows the composing influence of the medicine is peculiarly light and refreshing.

Caution.—Owing to the frequent complaints made by Physicians and General Practitioners of the distress and disappointment caused by the substitution of fraudulent imitations of Dr. J. Collis Browne's Chlorodyne, when prescribed by them for patients, as also vended to them as the genuine (proofs of which are in possession), it is found necessary to adopt the Government Stamp, having the name of Dr. J. Collis Browne's Chlorodyne engraved thereon.

Medical men, Hospitals, and Dispensaries, desirous of obtaining it without stamp, must forward their orders direct, duly authenticated, to the manufactory, when they can be supplied in bulk, a liberal discount being allowed.

Price 3s. per ounce, and in quantity of 10 ounces carriage free.

Sole Agent and Manufacturer—J. T. DAVENPORT, Operative and Pharmaceutical Chemist,
33, GREAT RUSSELL-STREET, BLOOMSBURY-SQUARE, LONDON.

DR. DE JONGH'S
(Knight of the Order of Leopold of Belgium)

LIGHT-BROWN COD-LIVER OIL.

CAUTION.

Serious and repeated complaints having been made of a discreditable system pursued by many Chemists and Druggists of intrusively recommending or surreptitiously substituting a pale, yellow, or coarse brown preparation, when Dr. de Jongh's Oil is prescribed, the Medical Profession are respectfully and earnestly solicited to afford their assistance in counteracting and repressing a practice alike injurious to their patients and to the fair repute of a remedy now held in such high and general estimation. In all cases where this Oil cannot be procured from a respectable Chemist, application should be made to Dr. de Jongh's Agents,

ANSAR, HARFORD, & CO., 77, Strand, London, W.C.

By whom any quantity will be immediately forwarded.

WALTERS' INDIA-RUBBER URINALS.

F. WALTERS having originally invented these Urinals, begs to warn the Profession of the many bad and useless imitations which are now sold, and he would advise them, before purchasing, to look that they are stamped with his name; as, unless that be the case, he cannot guarantee them.

These conveniences are made for those who require them only occasionally, during a long journey, as well as for those invalids who use them always. MR. WALTERS has much improved them by making them of *Etherised India-Rubber*, which adds very greatly to the strength of the India-Rubber, at the same time that it prevents its sticking together; by this means he is enabled to make them less stiff and harsh than hitherto, and yet to retain all the advantages of that stiffness. There is a patent valve, which prevents the return of the fluid; and they may be worn either sitting, walking, or lying, without the slightest inconvenience, and without being perceived by any one.

WALTERS' CONVENIENCES FOR LADIES will be found particularly useful during pregnancy. They are perfectly soft and flexible, and may be worn with perfect comfort.

All Orders must be accompanied by a Post-office order or reference.—Entrance for Ladies at the private door, where a Female attends.

MANUFACTURER OF ELASTIC STOCKINGS, BELTS, &c.

16, MOORGATE STREET, NEAR THE BANK, LONDON. E.C.

PURE SPIRITS FOR THE FACULTY.

S. V. R. 56 o.p., 17s. net Cash.—
This quotation admits of neither credit nor discount, and 1s. per gallon must be added for packages, to be allowed on their return.
HENRY BRETT and CO., Old Furnival's Distillery, Holborn.

Newbery's Cod-Liver Oil Cakes.—

"The gingerbread is extremely light and pleasant, the flavour of the oil being completely covered."—*Medical Times and Gazette*, 12th February, 1859. Packets, 1s. 9d. and 3s. **F. NEWBERY and SONS** (Proprietors of the "**PULVIS JACOBI VER. NEWBERY'S**"), 45, St. Paul's-Churchyard, London. ESTABLISHED A. D. 1746.

Pepsine.—**M. Boudault** begs to state

that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, **Mr. PETER SQUIRE**, her Majesty's Chemist, 277, Oxford-street, London, to whom all applications respecting it must be addressed.

Second Edition of Boudault on "Pepsine," with Remarks by English Physicians. Edited by **W. S. SQUIRE**, Ph. D., published by **J. Churchill**, London, may be also had of the Author, 277, Oxford-street, price Sixpence.

Superphosphate of Iron and Super-
PHOSPHATE OF IRON and LIME. New Remedial Agents introduced to the notice of the Profession at the Meetings of the Medical Society of London, and now extensively employed by the most eminent members of the Medical Profession. The Syrup is the most eligible mode of administering these valuable Remedial Agents. **Mr. GREENISH** will be happy to forward a variety of cases which have been furnished to him, where its success has been most marked, and which will serve to indicate where it may be most advantageously employed.—20, New-street, Dorset-square.

H. Silverlock's Medical Label Ware-

HOUSE, Letter-Press, Copper-plate, and Lithographic Printing Offices, Wardrobe-terrace, Doctors'-commons, London, E.C.

H. SILVERLOCK'S stock of Labels for Dispensing purposes having been recently revised and enlarged, now consists of upwards of 800 different kinds. Yellow and Green Labels for Drug Bottles, Drawers, &c., at per book or dozen: a Book, containing a selection in general use in Surgeries or Dispensaries, 10s. 6d. Priced Catalogues of the above may be had, post free, on application. Printing of every Description at Moderate Prices.

Bastick's more Certain Forms of
REMEDIES. LIQUOR COLCHICINÆ, LIQUOR HYOSCYAMINÆ, LIQUOR SMILACINÆ, &c.

These preparations are manufactured by processes which guarantee that each dose of these liquors contains an uniform quantity of the active constituents of colchicum, hyoscyamus, and sarsaparilla respectively, in their most effective forms.

"We shall be glad to see such solutions of the active principles of our most important drugs placed in the British Pharmacopœia."—*Medical Times*, January 29.

Pharmaceutical Laboratory, 2, Brook-street, Bond-street, London.

W. Twinberrow begs to draw the

attention of the Medical Profession to his **EXTRACT OF INDIAN HEMP**, prepared expressly for him at Calcutta, its peculiar sedative properties being so beneficial where opiates are inadmissible. Also to his **MEDICINAL EXTRACTS**, prepared from the fresh plants (*Hyoscyamus Niger*, *Conium Maculatum*, *Atropo*, *Belladonna*, *Cotyledon Umbilicus*, &c.) Also to his *Liq. Taraxici*, *Liq. Galli Aparinis* (a valuable alternative), *Liq. Parietariae* (diuretic), and *Liq. Beloe* (prepared from the *Ægle Marmelos*, or *Indian Bael*), for dysentery and diarrhoea. **W. T.** has a large supply of **INDIAN BAEL** on hand. 2, Edwards-street, Portman-square.

BOUDAULT'S PEPSINE imported in original bottles. *Ext. Loricis Europ.*

Varicose Veins and Supporting Bands.

—**SURGICAL ELASTIC STOCKINGS AND KNEE CAPS**, pervious, light in texture, and inexpensive, yielding an efficient and unvarying support, without the trouble of lacing. Likewise, a strong low-priced article for Hospitals and the Working-Classes. **ABDOMINAL SUPPORTING BANDS** for both Sexes; those for Ladies' use, before and after accouchement, are admirably adapted for giving adequate support with extreme lightness—a point little attended to in the comparatively clumsy contrivances and fabrics hitherto employed. Instruction for measurement and prices on application, and the articles sent by post from the Manufacturers and Inventors, **POPE and PLANTE**, 4, Waterloo-place, Pall-mall, London, S.W.

The Profession, Trade, and Hospitals, supplied

Williams and Son's Pure Glycerine

SOAP. Analysed by **Dr. Hofmann**, F.R.S., and **Professor Redwood**, Ph.D., strongly recommended by many eminent members of the Medical Profession, and favourably noticed by the following Medical Journals:—

THE LANCET.
THE MEDICAL TIMES AND GAZETTE.
THE BRITISH MEDICAL JOURNAL.
THE MEDICAL CIRCULAR.
EDINBURGH MEDICAL JOURNAL.
THE DUBLIN HOSPITAL GAZETTE.

It is suited to all cases of delicate skin (whether arising from disease or otherwise), and is admirably adapted for nursery use. May be had of all respectable Chemists, Perfumers, &c.

SOAP-WORKS, CLERKENWELL, LONDON, E.C.

Microscopic Glass.—Thin Glass for

Mounting Objects, in squares or circles. Slides 3 in. by 1 in. and Cells of every kind, supplied Wholesale and Retail, by
CLAUDET and HOUGHTON, 89, High Holborn, London.

J. & E. BRADSHAW, late
Shoolbred and Bradshaw,
34, JERMYN-STREET.

begs to call attention to the various improvements in Patent **ELASTIC STOCKINGS, BELTS, KNEE-CAPS, SOCKS**, and **Ladies' and Gentlemen's SPINE SUPPORTERS**. A new description of **BELT**, invaluable for prevention of Cholera and the cure of Rheumatism, Lumbago, &c.

N.B. Every description of **INDIA-RUBBER BANDAGE**, vulcanised on the newest principle. Directions for measurement sent by post. **N.B.** A Liberal Discount to the Profession. A Female to attend on Ladies.

Crosse and Blackwell, Purveyors in

Ordinary to Her Majesty, respectfully invite attention to their **PICKLES, Sauces, Tart Fruits**, and other table delicacies, the whole of which are prepared with the most scrupulous attention to wholesomeness and purity. The practice of colouring pickles and tart-fruits by artificial means has been discontinued, and the whole of their manufactures are so prepared that they are not allowed to come in contact with any deleterious ingredient. A few of the articles most highly recommended are, **Pickles and Tart Fruits** of every description, **Royal Table Sauce**, **Essence of Shrimps**, **Soho Sauce**, **Essence of Anchovies**, **Jams**, **Jellies**, **Orange Marmalade**, **Anchovy and Bloater Pastes**, **Strasbourg** and other **Potted Meats**, and **Calf's-Foot Jellies** of various kinds for table use. **C. and B.** are also sole agents for **M. Soyer's Sauces, Relish, and Aromatic Mustard**; and for **Carstairs' Sir Robert Peel's Sauce**, and **Payne's Royal Osborne Sauce**. The above may be obtained of most respectable Sauce Vendors throughout the United Kingdom; and Wholesale of
CROSSE and BLACKWELL, 21, Soho-square.

Pillischer's Achromatic Microscopes.—

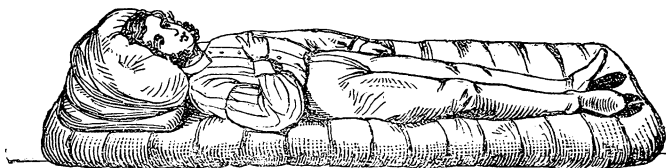

To meet the daily increasing demand for his Microscopes, **M. PILLISCHER** has recently completed extensive alterations in his workshops to enable him to manufacture **MICROSCOPES** and their **Object Glasses** upon a more expeditious and extensive scale. **M. P.** has the pleasure of informing the Profession that he is now able to furnish Microscopes of the very greatest perfection; possessing every modern improvement; and with **Object Glasses** of a quality unsurpassed by any other maker, on the shortest notice, and at very moderate prices.

PILLISCHER'S £7 7s. STUDENTS' MICROSCOPE, for which a prize Medal was awarded to him at Paris Exhibition, 1855, deserves particular notice. It consists of a well-constructed Stand, with coarse and fine adjustments, a capital Stage, with Diaphragm and Large Mirror, one Eye-glass, one and one quarter inch Object Glasses, 16" and 75" Microscope when further completed with the addition of a Second Eye-glass, Condenser for Opaque Objects, Live Box, Stage Forceps, large Glass Stage, and Polarising Apparatus, price £10, forms a most complete and valuable Microscope, and in every respect as useful as a much more expensive one.

A Catalogue post free on application to **M. Pillischer**, Optician, 88, New Bond-street, London, W.

WATER BEDS.—EDMISTON and SON, 5, Charing-Cross, beg to call

the particular attention of the Managers of Hospitals and Dispensaries, and the Medical Profession generally, to the prices and quality of their Hot or Cold Water Beds. The prices hitherto charged being so high as to limit the sale of such articles to the affluent, they are induced to offer them at such prices as will enable the public generally to realise the advantage and comfort to be derived from their use.

WATER BEDS, £3 13s. 6d., £5 5s., and £6 16s. 6d.

Water Pillows and Cushions, 7s. 6d. to 21s. Urinals, from 3s. 6d. to 12s. 6d. Cotton Elastic Stockings, 4s. 3d. Silk, 5s. 3d. Knee Caps, Leggings, Anklelets, &c.

BED SHEETS, ACCOUCHEMENT BELTS, &c.

India-Rubber Chamber Utensils for Lunatic Asylums, 7s. 6d. each, or 75s. per dozen.

WATER BEDS ON HIRE. TERMS, 7s. 6d. PER WEEK.

LONDON: EDMISTON AND SON, 5, CHARING-CROSS, LATE 69, STRAND.

ARTIFICIAL LEGS AND HANDS.

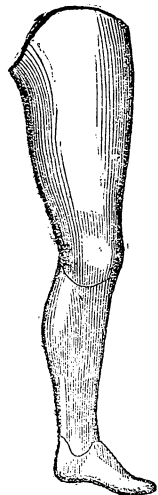

PARIS PRIZE MEDAL, 1855.

GROSSMITH'S NEW ARTIFICIAL LEG,

WITH PATENT ACTION, KNEE AND ANKLE JOINTS,

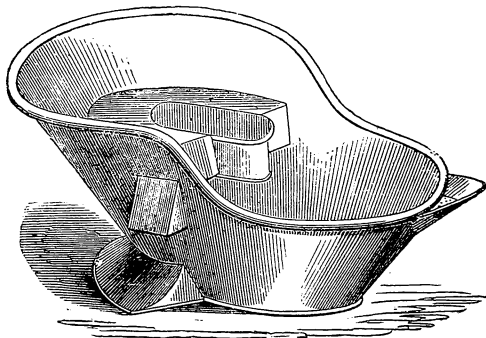

Enables the patient to walk, sit, or ride with ease and comfort, wherever amputated. It is much lighter and less expensive than the old style of cork leg, will last a lifetime, and is the only leg yet invented that Ladies and Children can wear with safety. It was awarded the highest Medal at the recent Paris Exposition, although more than twenty other makers from different nations exhibited. Can be obtained only at Grossmith's Manufactory, 175, Fleet-street, London (Established 1760); of Fannin and Co., Dublin, or at Charrieres, Paris.

*** Artificial Hands and Arms, Fingers, Eyes, Noses, &c., with all the most recent patent improvements.

Oxley's Patent Multum-in-Parvo Bath.

Sole Makers, GRIFFITHS and BROWETT, 68, BRADFORD-STREET, BIRMINGHAM; and to be had of all respectable Ironmongers.

The convenience of a Bidet, Sponge, Hip, Foot, and Nursery Bath are here combined, which renders it not only the best for general purposes, but indispensable for the Invalid, to whom it may confidently be recommended by members of the Medical Profession as the most comfortable and useful Bath extant.

Pratt's Artificial Leg.

J. PRATT begs to call the attention of the Profession to the following Testimonial, just received:—

"Somerset,

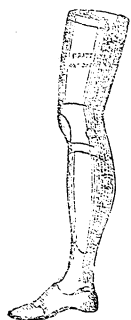

June 20th, 1858.

"DEAR SIR,—It affords me much pleasure in being able to state that the Artificial Leg which you supplied me with is far beyond my best anticipations. From its being so LIGHT in weight, and its action in the foot so natural, I can walk, or ride on horseback, with ease and comfort; and few indeed would detect it as being other than natural. It has given me full satisfaction.

I am, dear Sir, yours very truly,

J. W.

To Mr. J. Pratt,
Surgical Instrument Maker,
420, Oxford-street."

GLENFIELD PATENT STARCH,

USED IN THE ROYAL LAUNDRY,

AND PRONOUNCED BY HER MAJESTY'S LAUNDRESS to be THE FINEST STARCH SHE EVER USED.

Sold by all Chandlers, Grocers, &c. &c.

TRADE MARK.

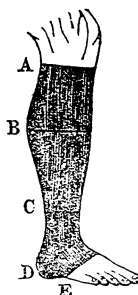

SUMMER DIET.

BROWN & POLSON'S PATENT CORN FLOUR.

This is superior to anything of the kind

known—LANCET. Obtain it from Family Grocers, or Chemists, who do not substitute inferior articles. It is preferred to the best Arrow Root; for Breakfast boiled simply with milk; Dinner or Supper, in Puddings, warm or cold, Blancmange, Cake, &c., and especially suited to the delicacy of Children and Invalids. Packets, 16 oz. 8d.

Voullion's Patent Elastic SPIRAL SUPPORTS, "WITHOUT SEAMS OR LACING."

200 Leading Members of the Medical Profession recommend them in preference to all others.

DIRECTIONS FOR MEASUREMENT:—

For STOCKINGS—Circumference round the instep, ankle, calf, and above calf.

For KNEE-CAPS—Circumference below knee, at knee, and above knee.

For THIGH-PIECE—Circumference round top and bottom of thigh.

For ABDOMINAL SUPPORTS—Circumference of body above and below the hips.

Illustrated and Priced Catalogues free. Prices reduced 30 per cent.

MEACHER, Operative Chemist, sole Manufacturer, 105, Crawford-street, Portman-square.

Scammony Manufactured from the

ROOT.—This Pure Resin may be had of all Wholesale Druggists at 28s. per lb.

The Medicinal value of this Scammony was fully explained at a meeting of the Pharmaceutical Society, and reported at length in their journal of March last, from which the following are extracts:—

"From these numerous observations, one hundred and twenty in number, together with many others which have not been tabulated, I am quite convinced that the scammony prepared by the new process from the untapped root is quite equal, as a remedy, to the very best virgin scammony which is met with in commerce, and equal, in fact, to the resin which is extracted from commercial scammony by means of ether; and it possesses this most important advantage over the scammony of commerce, namely, of being entirely free from the frauds which are almost constantly practised upon it in the country where the plant grows, and in which it has hitherto been collected, and, therefore, being perfectly uniform in its physical characters, composition and therapeutic action. There can, therefore, be no objection, but, on the other hand, manifest advantage, in employing it in place of the scammony commonly met with."

"A. B. GARROD, M.D., F.R.S., F.R.C.P.

"Professor of Materia Medica, Therapeutics and Clinical Medicine at University College; Physician to University College Hospital."

"I have endeavoured to ascertain the relative activity of Messrs. M'Andrew's scammony, and of a fine specimen of commercial virgin scammony, by prescribing these drugs alternately in equal doses to the same patient. The results, according to the judgment of myself and others who have assisted me in watching the cases, is that in most instances Messrs. M'Andrew's scammony has proved itself decidedly more active than the virgin scammony. As to pleasantness of operation, or the reverse, there seemed to be no choice between the two specimens.

"That a preparation of scammony should be a little more or a little less active is of comparatively small importance. It is far more important that the drug should have a fixed and uniform composition and activity, so that the prescriber may know, with an approach to certainty, what doses are required to produce a given effect. This advantage of uniform activity Messrs M'Andrew's scammony seems likely to possess over the scammony which has hitherto been in common use, and which is a drug notoriously of most uncertain composition and power."

"GEORGE JOHNSON, M.D., F.R.C.P.

"Professor of Materia Medica and Therapeutics in King's College; Physician to King's College Hospital."

MEDICAL AGENCY.

NOTICE OF REMOVAL AND CHANGE OF FIRM.

Mr. Lara (for the last eight years the sole representative of LANE and LARA, Medical Agents and Arbitrators and Lunatic Asylum Registrars,) begs to inform the Profession that, in consequence of the daily increasing support with which he has been favoured, and for which he tenders his sincerest thanks and acknowledgments, he has taken into PARTNERSHIP Mr. James Maxfield Walters, a gentleman who has had considerable experience in the business. It will, therefore, from and after Christmas, 1858, be carried on, under the Firm of LARA and WALTERS, at 6, PUMP-COURT, Middle Temple, E.C., whither they have removed their Offices from 22, Buckingham-street, Adelphi, in order to provide that larger accommodation which a constant intercourse with a great majority of the entire body of General Practitioners in England has rendered necessary.

Partnerships and Practices sold and valued: Asylums transferred: Arbitrations effected: Assistants provided (if for a permanence without charge to Employers): and every other description of business transacted for the Profession at a fixed and moderate cost. Attendance from 11 till 4.

Operations.—East India, Army and NAVY EXAMINATIONS.—Mr. CHRISTOPHER HEATH, Demonstrator of Anatomy at the Westminster Hospital (formerly House-Surgeon to King's College Hospital), is prepared to Superintend the Performance of the Operations on the Dead Body. Fee, including an entire subject and the necessary instruments, Six Guineas; or with half a subject, Four Guineas. Apply to Mr. Heath, at the Westminster Hospital.

Samaritan Free Hospital for Women and CHILDREN, 18, EDWARDS-STREET, PORTMAN-SQUARE.—There is a VACANCY for HOUSE-SURGEON at this Hospital. Gentlemen qualified for registration under the Medical Act, desirous of obtaining the appointment, are requested to send in their applications on or before the 1st of August, directed to the Assistant-Secretary, as above. Copies of rules, &c. can be obtained by application at the Hospital.

Stourbridge Dispensary.—Wanted, a

HOUSE-SURGEON and SECRETARY. Salary, £120 per annum, with house and coals. Candidates must be Members of the Royal College of Surgeons and Licentiates of the Apothecaries' Company, London. The Gentleman elected will be required to enter into an agreement not to practise within three miles of the town until three years have elapsed after resigning the appointment. Applications and testimonials to be forwarded to Mr. Way, the present House-Surgeon, on or before the 20th day of August. The Election will take place the following Tuesday. Duties commence September 30th.—Stourbridge, July 11, 1859.

Manchester Royal Infirmary and DISPENSARY. Weekly Board, July 25th, 1859.—WANTED, in consequence of a vacancy about to occur, an Unmarried Gentleman as PHYSICIANS' ASSISTANT to these Charities. Every candidate for the office will be required to produce a diploma from one of the Royal Colleges of Surgeons in London, Edinburgh, or Dublin, and be a Licentiate of the Worshipful Society of Apothecaries, London, or he shall be a Graduate of Medicine of the London University. The gentleman who may be elected will be required to remain in the situation for a term of not less than two years, to reside in the house, and devote the whole of his time to the duties of the office; which duties consist in visiting and prescribing for the home and out patients. Salary, 60 guineas a year, with board and lodging. Letters from candidates, with their diplomas and other testimonials, must be sent (free of charge) on or before Saturday, the 20th August next to the Secretary, at the Royal Infirmary.—By order of the Board.

ROBT. THORPE RADFORD, Secretary.

Addenbrooke's Hospital, in the Town

of CAMBRIDGE.—HOUSE APOTHECARY.—NOTICE IS HEREBY GIVEN, that a SPECIAL GENERAL COURT of the PRESIDENT and GOVERNORS of the above Institution, will be held in the Board-Room of the said Hospital, at Eleven o'clock in the forenoon of the 5th SEPTEMBER next, for the ELECTION of a GENTLEMAN, to fill the office of House Apothecary, vacant by the resignation of Mr. Edmund Carver. The Gentleman elected will have to reside, and will be boarded in the Institution. The Salary is £36 a year. All Candidates must be duly qualified, and must forward Testimonials as to ability and character, sealed up, under cover, to the Secretary, before the 31st of August, and must produce their qualifications to the Court, on the day of Election. And notice is hereby further given, that in case of a contest, votes will be received by the Court, at the Board-Room, from 12 o'clock at noon, until 5.30 o'clock in the afternoon of the said fifth day of September, when the Election will finally close. Ladies only can vote by proxy, forms of which, and all particulars, may be had upon application, at the office of the Secretary. By Rule 24 no Governor can be allowed to vote whose Subscription is unpaid; nor unless he has been a Governor for six months, except he be a benefactor of Twenty Guineas and upwards. Annual Subscriptions became due on the 29th of September last, and as Subscriptions are paid in advance for the current year, all Governors by yearly subscription of two guineas must pay their Subscriptions up to the 29th September, 1859, together with all arrears, if any, to EDMUND JOHN MORTLOCK, Esquire, Banker, Cambridge, the Treasurer, before their votes can be received. By order, FREDERIC BARLOW, Secretary.

St. Andrew's-street, June 30th, 1859.

For Disposal, a Practice, with an

APPOINTMENT, in a Capital Town in one of the Home Counties. Purchase Money, £500. For particulars, address, A. B., 21, Harp-lane, London, E.C.

Medical Transfer and Partnership.

30, Bucklersbury, Cheapside.

Mr. Orridge, Medical Transfer Agent,

Referee, and Valuer of Medical Property, may be consulted, at the above Address, by Gentlemen about to receive PARTNERS, or to RELINQUISH or to COMMENCE Practice.

Mr. Orridge is known to many of the Hospital Physicians and Surgeons of London.

He has been concerned professionally for a considerable proportion of the most influential Practitioners (including Partners in many of the leading Medical Firms), to whom he has the satisfaction of being permitted to refer—a privilege that he trusts will be regarded as a proof of the sincerity of his endeavours to conduct these transactions in an honourable and straightforward manner.

Gentlemen desirous of obtaining Mr. Orridge's opinion, or requiring his attendance professionally in any part of England, can obtain terms on application, by (confidentially) transmitting name and address.

Office Hours, from Eleven to Four.

Mr. James Robinson, Dentist, has

REMOVED from No. 7 to No. 5, GOWER-STREET, Bedford-square, London, where he may be CONSULTED daily from 10 to 4. 5, Gower-street, Bedford-square.

To Surgeons.—For Disposal near

Russell-square, a SMALL GENTLE PRACTICE. A Chemist Retail may be purchased with it if desired. Satisfactory reasons for leaving, and a good introduction given. Particulars of Mr. Humpage, 44, Chancery-lane, W.C.

In-door Assistant Wanted, in a

Provincial Town. A Gentleman possessing the Double Qualification, and duly registered, will be required to assist in Dispensing. Salary, £80 per annum. The most satisfactory references required. Address, Messrs. CORBYN & Co., 300, Holborn, London.

A Practice to be Disposed of, in con-

sequence of ill-health, situated in one of the most populous districts in the North of London. Established twenty years. Capable of great extension. Immediate possession may be had. In-coming about £320. For particulars, apply to A. B., 19, Chapel-street, Pentonville-hill, before eleven or after five.

Wanted, in a Town in the North of

England, an ASSISTANT, to Visit, Dispense Medicines, and attend Midwifery. Apply to X. Y. Z., Medical Times and Gazette Office, London.

Partnership.—Wanted immediately, a

Young Man of gentlemanly bearing, fully qualified, to enter into PARTNERSHIP with an experienced Practitioner, in one of the Suburbs of London, where there is an unusual opening for a good Practice. As the onus of business would for some time devolve on the Junior Partner, no Premium will be required. Address (stating age, real name, &c.), for further particulars, to A. H., Mr. Dryland, 7, Great St. Helen's, Bishopsgate-street.

Carriages, New and Second-hand, of

superior style, sterling quality, and finest finish at reasonable rates, for cash, credit, job, or exchange. Circular of prices on application. Credit given when required. Buyers should take carriages on trial, with power to purchase by yearly payments, and thus prove them.

OFFORD'S PATENT MEDICAL MAN'S BROUGHAM MANUFACTORY, 79, WELLS-STREET, OXFORD-STREET.

Surgical Instruments, and every Im-

plement necessary for Surgeons and Druggists, can be had (warranted best quality and moderate prices), retail as well as wholesale, from the Manufacturer, JAMES ARNOLD, 35, WEST SMITHFIELD, St. Bartholomew's Hospital, London.

Single Circular Truss, 2s. 6d.; double ditto, 5s.; on Salmon's Expired Patent, 4s. 6d.; double ditto, 9s.; on Coles's Expired Patent, 5s.; double ditto, 10s.; Cotton Net Suspensory Trusses, from 10d.; Elastic Stocking Net bandage, 4d. per yard; Case of Tooth Instruments, £1; Case of Cupping Instruments, £2 13s. 6d.; Case of Pocket Instruments, £1; Brass Enema Syringe, complete in mahogany case, 10s. and 12s.; Case of Dissecting Instruments, Ivory Handles, 15s.; best Bleeding Lancets, per dozen, 18s.

POULTICES SUPERSEDED! SPONGIO PILINE.

The Profession are respectfully

informed, that the WANDLE FELT COMPANY having purchased Mr. MARKWICK'S PATENT for the well-known SPONGIO PILINE, for the application of moist heat, in lieu of Poultices and Fomentations, and the IMPERMEABLE PILINE, for Rheumatism, for promoting perspiration, and for the application of stimulating liniments, are now supplying these articles, of superior manufacture, and at greatly reduced prices, at 27, BEDFORDBURY, COVENT-GARDEN, London, and also through the Wholesale and Retail Druggists in town and country.

London: Printed by CHARLES REED and BENJAMIN PARDON of 1, 2, and 3, Lovell's-court, Paternoster-row, in the City of London, and published by JOHN CHURCHILL, at the Publishing Office, No. 11, New Burlington-street, in the Parish of St. James, in the City of Westminster.—July 30, 1859.

Just published, in One Vol. 8vo, price 7s. 6d.
A Treatise on Medical Electricity.

By J. ALTHAUS, M.D.

"There existed a hiatus in British Medical literature on the subject which the present work most worthily fills up. Dr. Althaus' Treatise is complete, accurate, and scientific. . . . The book is written in a clear and even elegant style. Dr. Althaus does not address us with the enthusiasm of a specialist, but with the honest conviction of a man of science; and hence we feel sure that his book will prove acceptable to the Profession, and will serve to diminish the ignorance which prevails upon the employment of electricity in medicine, while it will materially assist in establishing the claims of this agent upon our serious attention."—British and Foreign Med.-Chir. Review.

"Dr. Althaus has supplied to the English Profession by far the most elaborate and useful book on the subject upon which it treats extant in our mother tongue. . . . The book will command general reference. We expect to see it for some time to come the standard English work on Medical Electricity."—Medical Times and Gazette.

Great Saving in the Purchase of New

MEDICAL GLASS BOTTLES and PHIALS at the NORTH LONDON GLASS BOTTLE WORKS, ISAACS and SON (Proprietors).—London Warehouses, 24 and 25, Francis-st., Tottenham-court-road, W.C.
6 and 8 oz., any shape, plain, or graduated } clear { 8s. per gross.
3 and 4 oz., do. ditto } blue tinted { 7s. 6d. do.
1 oz. Moulded Phials } of a very { 4s. 6d. do.
1 oz. ditto } superior { 5s. 6d. do.
1 1/2 oz. ditto } quality. { 6s. 0d. do.
2 oz. ditto } { 7s. 0d. do.

A remittance not required till the goods are received. Packages free. Delivered free within seven miles. Post-office Orders payable to "S. Isaacs and Son," at Tottenham-court-road. Bankers: Unity Bank.

Crosse and Blackwell, Purveyors in

Ordinary to Her Majesty, respectfully invite attention to their PICKLES, Sauces, Tart Fruits, and other table delicacies, the whole of which are prepared with the most scrupulous attention to wholesomeness and purity. The practice of colouring pickles and tart-fruits by artificial means has been discontinued, and the whole of their manufactures are so prepared that they are not allowed to come in contact with any deleterious ingredient. A few of the articles most highly recommended are, Pickles and Tart Fruits of every description, Royal Table Sauce, Essence of Shrimps, Soho Sauce, Essence of Anchovies, Jams, Jellies, Orange Marmalade, Anchovy and Bloaters Pastes, Strassbourg and other Potted Meats, and Calf's-Foot Jellies of various kinds for table use. C. and B. are also sole agents for M. Soyer's Sauces, Relish, and Aromatic Mustard; and for Carstairs' Sir Robert Peel's Sauce, and Payne's Royal Osborne Sauce. The above may be obtained of most respectable Sauce Vendors throughout the United Kingdom; and Wholesale of CROSSE and BLACKWELL, 21, Soho-square.

Struve's Seltzer, Marienbad, Vichy,

KISSINGEN, and other MINERAL WATERS.—Under her Majesty's especial Patronage.—ROYAL GERMAN SPA, BRIGHTON, STRUVE'S PUMP-ROOM and PROMENADES, offering every facility for a Course of Mineral Waters, as perfect and beneficial as at the natural springs, are NOW OPEN, for the Thirty-fifth Season. A prospectus, with the highest Medical testimonials, may be obtained gratis, at the Pump-room, or from George Waugh and Co. Chemists to the Queen, 177, Regent-street (westside), London, and other respectable houses in London and the provincial towns, where orders for Struve's Bottled Mineral Waters continue to be executed.

CAUTION.—The success obtained by Struve's Mineral Waters, owing to their perfect identity with those of the natural springs, has induced several parties to attempt imitations, sold as "Brighton Seltzer," "Brighton Vichy," &c., an analysis of some of which has shown an utter disregard of their true chemical composition. To distinguish Struve's Waters from all others, every bottle has a label and red ink stamp over the cork, each bearing Struve's name, without which name none is genuine, though contained in Struve's old bottles.

Great Reduction in the Prices of New

MEDICAL GLASS BOTTLES and PHIALS, at the Islington Glass Bottle Works, Islington-place, Park-road. London Warehouses, 19, Bread-street-hill, near Thames-street, City, E.C., and 2, Upper Copenhagen-street, Barnsbury-road, Islington. E. and H. HARRIS and CO. Proprietors.

6 & 8 oz., any shape, plain or graduated } clear { 8s. per gross.
3 & 4 oz., do. do. } blue tinted { 7s. 6d. do.
1 oz. white moulded phials } of a very { 4s. 6d. do.
1 oz. do. } superior { 5s. 6d. do.
1 1/2 oz. do. } quality. { 6s. 0d. do.
2 oz. do. } { 7s. 0d. do.

Immediate attention to country orders. No remittance required until the goods are received. Packages free. Goods delivered free within 7 miles. Post-office orders made payable to E. and H. HARRIS and Co., at the Chief Office, London. Bankers: Union Bank of London.

N.B.—Orders sent to either Establishment will have prompt attention.

Health, Fresh Air, and Pure Water.

—By Her Majesty's Letters Patent.—CONDY'S FLUID contains NASCENT OXYGEN, nature's true and only purifying agent; instantly removes all offensive smells; renders impure water fresh, and the air pure; when diluted for use, is of a beautiful colour, not soiling the finest linen; is harmless, and particularly adapted for toilet use, being both refreshing and exhilarating. The Medical Profession have expressed their unqualified approbation of its merits. One gallon makes 200 gallons adapted for use. The cooling, healing, gently stimulating and invigorating properties of this Fluid render it, when diluted, a lotion possessing peculiar and valuable characteristics, whether for bathing the bodies of invalids, incorporating in poultices, or washing and healing wounds. Patronised by the Board of Health, and most public departments, hospitals, schools, and adopted by the India Council in preference to all other disinfectants. In bottles, 6d. 1s. and 2s.; stronger and purer, 1s. 2s. and 4s.

CONDY'S PATENT HEALTH POWDER also contains NASCENT OXYGEN, is odourless, and destroys all smells; in bottles, 1s. 6d. and 3s., and in casks of 1 cwt. 36s.

Wholesale agents, John Bell and Co. chemists, No. 338, Oxford-st. W.; Butler and Crisp, 5, Cheapside, St. Paul's.—Chemical works, Battersea, S.W.

Scammony Manufactured from the ROOT.—This Pure Resin may be had of all Wholesale Druggists at 2s. per lb.

The Medicinal value of this Scammony was fully explained at a meeting of the Pharmaceutical Society, and reported at length in their journal of March last, from which the following are extracts:—

"From these numerous observations, one hundred and twenty in number, together with many others which have not been tabulated, I am quite convinced that the scammony prepared by the new process from the untapped root is quite equal, as a remedy, to the very best virgin scammony which is met with in commerce, and equal, in fact, to the resin which is extracted from commercial scammony by means of ether; and it possesses this most important advantage over the scammony of commerce, namely, of being entirely free from the frauds which are almost constantly practised upon it in the country where the plant grows, and in which it has hitherto been collected, and, therefore, being perfectly uniform in its physical characters, composition and therapeutic action. There can, therefore, be no objection, but, on the other hand, manifest advantage, in employing it in place of the scammony commonly met with.

"A. B. GARROD, M.D., F.R.S., F.R.C.P.

"Professor of Materia Medica, Therapeutics and Clinical Medicine at University College; Physician to University College Hospital."

"I have endeavoured to ascertain the relative activity of Messrs. M'Andrew's scammony, and of a fine specimen of commercial virgin scammony, by prescribing these drugs alternately in equal doses to the same patient. The results, according to the judgment of myself and others who have assisted me in watching the cases, is that in most instances Messrs. M'Andrew's scammony has proved itself decidedly more active than the virgin scammony. As to pleasantness of operation, or the reverse, there seemed to be no choice between the two specimens.

"That a preparation of scammony should be a little more or a little less active is of comparatively small importance. It is far more important that the drug should have a fixed and uniform composition and activity, so that the prescriber may know, with an approach to certainty, what doses are required to produce a given effect. This advantage of uniform activity Messrs M'Andrew's scammony seems likely to possess over the scammony which has hitherto been in common use, and which is a drug notoriously of most uncertain composition and power.

"GEORGE JOHNSON, M.D., F.R.C.P.

"Professor of Materia Medica and Therapeutics in King's College; Physician to King's College Hospital."

WINES FROM SOUTH AFRICA.

Denman, Introducer of the South

AFRICAN PORT, SHERRY, &c. 20s. PER DOZEN, BOTTLES INCLUDED.

A PINT SAMPLE OF EACH FOR 24 STAMPS.

J. & E. BRADSHAW, late

Shoolbred and Bradshaw, 34, Jermyn-STREET, begs to call attention to the various improvements in

PATENT ELASTIC STOCKINGS, BELTS, KNEE-CAPS, SOCKS, and Ladies' and Gentlemen's SPINE-SUPPORTERS. A new description of BELT invaluable for prevention of Cholera, and the cure of Rheumatism, Lumbago, &c. —N.B. Every description of INDIA-RUBBER BANDAGE, vulcanized on the newest principle.

Directions for measurement sent by post. N.B. A liberal Discount to the Profession.

A female to attend on Ladies.

Mr. Howard, Surgeon-Dentist, 52, FLEET-STREET, has introduced an entirely NEW DESCRIPTION OF ARTIFICIAL TEETH, fixed without Springs, Wires, or Ligatures. They so perfectly resemble the natural teeth as not to be distinguished from the original by the closest observer; they will NEVER CHANGE COLOUR or DECAY, and will be found very superior to any teeth ever before used. This method does not require the extraction of roots, or any painful operation, and will give support and preserve teeth that are loose, and is guaranteed to restore articulation and mastication; and that Mr. Howard's improvements may be within the reach of the most economical, he has fixed his charges at the lowest scale possible. Decayed Teeth stopped and rendered sound and useful in mastication. 52, Fleet-street. At home from Ten till Five.

Varicose Veins and Supporting Bands.

—SURGICAL ELASTIC STOCKINGS AND KNEE CAPS, previous, light in texture, and inexpensive, yielding an efficient and unvarying support, without the trouble of lacing. Likewise, a strong low-priced article for Hospitals and the Working-Classes. ABDOMINAL SUPPORTING BANDS for both Sexes; those for Ladies' use, before and after accouchement, are admirably adapted for giving adequate support with extreme lightness—a point little attended to in the comparatively clumsy contrivances and fabrics hitherto employed. Instruction for measurement and prices on application, and the articles sent by post from the Manufacturers and Inventors, POPE and PLANTE, 4, Waterloo-place, Pall-mall, London, S.W.

The Profession, Trade, and Hospitals, supplied.

King's College, London.—Medical

DEPARTMENT.—The WINTER SESSION, 1859-60, will commence on SATURDAY, OCTOBER 1, 1859, on which day all students are expected to attend the Introductory Lecture, at Two o'clock.

The following Courses of Lectures will be given:—

Anatomy—Professor Richard Partridge, F.R.S.
Physiology; General and Morbid Anatomy—Professor Lionel S. Beale, M.B.
Chemistry—Professor W. A. Miller, M.D. F.R.S.
Principles and Practice of Medicine—Professor George Budd, M.D.
Principles and Practice of Surgery—Professor William Fergusson, F.R.S.

KING'S COLLEGE HOSPITAL.

George Budd, M.D. F.R.S. } With care of In-Patients.
R. B. Todd, M.D. F.R.S. }
George Johnson, M.D. }
W. A. Guy, M.B. F.R.S. } With care of Out-Patients.
Lionel S. Beale, M.B. F.R.S. }
Physician for Diseases of Women and Children and Physician-Accoucheur—Arthur Farre, M.D. F.R.S.
Assistant-Physicians—Charles Murchison, M.D.; Conway Evans, M.B.
Surgeons ... { W. Fergusson, F.R.S. } With care of In-Patients.
Richard Partridge, F.R.S. }
William Bowman, F.R.S. }
Henry Lee, F.R.C.S. ... } With care of Out-Patients.
Assistant-Surgeons—John Wood, F.R.C.S.; John W. Hulke, F.R.C.S.
Surgeon-Dentist—S. Cartwright, jun.

The Hospital is visited daily. Clinical Lectures are given every week, both by the Physicians and by the Surgeons. The Physicians' Assistants and Clinical Clerks, the House-Surgeons and dressers, are selected by examination from the Students of the Hospital.

SCHOLARSHIPS.—New Students will have the privilege exclusively of contending, in October, 1859, for five Warneford Scholarships—viz., two of £25 per annum, for three years, and three of £25 per annum, for two years. The Examination will commence on the 29th of September, in Divinity, Classics (subjects the same as for the Matriculation Examination this year at the University of London), Mathematics, History, and the Modern Languages.

One Scholarship of £40, tenable for two years; one of £30, for one year; and three of £20 each, for one year, will be filled up in April next, the subjects of the Examination being exclusively Medical.

Further particulars may be obtained from J. Harley, Esq., Sub-Dean of the Department; and a detailed Prospectus will be forwarded by application to J. W. Cunningham, Esq., Secretary.

R. W. JELF, D.D., Principal.

NO LIVE STOCK ON BOARD SHIP.

Joints of Beef and Mutton, also Poultry,

are now Preserved by HAND'S PATENT. That they will keep quite fresh in an uncooked state in all climates, and when eaten cannot be known from fresh-killed food, cooked meat need not now be taken.

For prices or samples apply to Mr. HESKETH S. DAVIS, 24, Leadenhall-street, London, E.C.

"PULVIS JACOBI VER. NEWBERRY'S."

Diphtheria, Fevers, Hooping Cough,

&c.—We beg to caution the Profession against imitations of this invaluable Medicine, for so many years prescribed as "Pulvis Jacobi Ver.," but to which it is now necessary to add the name "NEWBERRY'S," to secure prescribers against the SUBSTITUTION of articles advertised as James' Powder, BUT WHICH HAVE NOTHING IN CHARACTER, DOSE, OR EFFECT, with the original article, which has been prepared at 45, St. Paul's churchyard, continuously since its introduction in 1746.

Price: 1 oz. bottles, 11s.; ½ oz. do. 4s. 6d., with the usual allowance to the Profession. (Signed) F. NEWBERRY & SONS.

Williams and Son's Pure Glycerine

SOAP. Analysed by Dr. Hofmann, F.R.S., and Professor Redwood, Ph.D., strongly recommended by many eminent members of the Medical Profession, and favourably noticed by the following Medical Journals:—

THE LANCET.
THE MEDICAL TIMES AND GAZETTE.
THE BRITISH MEDICAL JOURNAL.
THE MEDICAL CIRCULAR.
EDINBURGH MEDICAL JOURNAL.
THE DUBLIN HOSPITAL GAZETTE.

It is suited to all cases of delicate skin (whether arising from disease or otherwise), and is admirably adapted for nursery use. May be had of all respectable Chemists, Perfumers, &c.

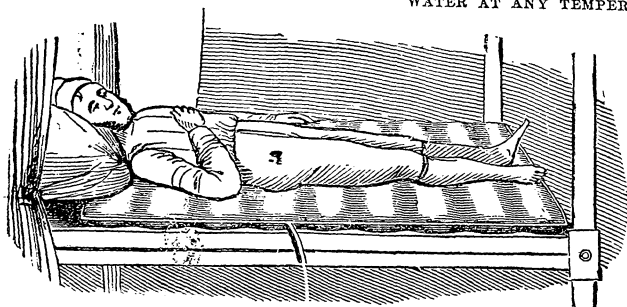

SOAP-WORKS, CLERKENWELL, LONDON, E.C.

The Bitter-Water of Friedrichs Hall

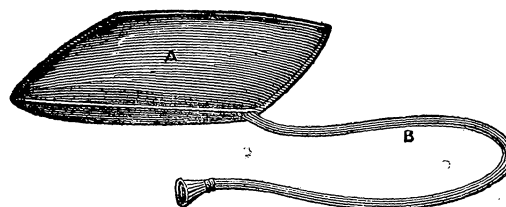

enjoys deservedly a very high reputation amongst Medical Men on the Continent, and in directing the attention of the Medical Profession in this country to the extraordinary virtues of this water, we can mention here only a few of the chief diseases in which it has been prescribed with the most beneficial results—viz., Diseases of the Stomach and Bowels, especially Indigestion, Loss of Appetite, and habitual Constipation; Enlargement and Indurations of the Liver, with or without Jaundice or Dropsy; Diseases of the Kidney, including Albuminuria. Affections of the Sexual Organs, and the numerous accidents which so many women are subject to at their critical age, and the inconveniences resulting from pregnancy; also Hypertrophy of the Heart, Determination of Blood to the Head and Lungs, Hypochondriasis, and Gout, must be mentioned. One peculiar advantage which this water possesses over most other bitter waters is, that it is given only in small quantities—viz., a wineglassful, either before breakfast or on going to bed; that it may be taken at all seasons, and requires neither a particular diet nor exercise in the open air. Further information, with cases, will be found in Dr. Eisemann's Monograph of this Water, which may be had gratis at Messrs. A. and R. THWAITES and CO.'s, 147, Regent-street, London, and 57, Upper Sackville-street, Dublin, who have just received a fresh supply of this Bitter-water.

HOOPER'S HYDROSTATIC BEDS, OR MATTRESSES AND CUSHIONS, FOR PLACING ON AN ORDINARY BEDSTEAD.

WATER AT ANY TEMPERATURE MAY BE USED.

HOOPER'S FULL-LENGTH MATTRESS OR HYDROSTATIC BED,
For Bedsores, Cancer, Coldness of the Body, Consumptive Cases, Diseased
Joints, Dropsy, Fevers, Fractures, Gout, Gun-shot wounds.

HOOPER'S CUSHION FOR GENERAL PURPOSES.

ANY SHAPED CUSHION CAN BE OBTAINED,

For Inflammation of the Bowels, Lassitude, Paralysis, Rheuma-
tism, Spinal Affections, Sloughing Sores, Ulcerated Cartilages,
and all Invalids.

HOOPER'S PATENT INVALID BED-LIFT.

THE OBJECT of this INVENTION is to enable the Patient to be raised in any position above the Bed, so as to allow the Medical Attendant, or Nurse, to get at any part of the body that may be requisite; and also that the Bed may be re-made, the chamber utensil used, and removed with facility.

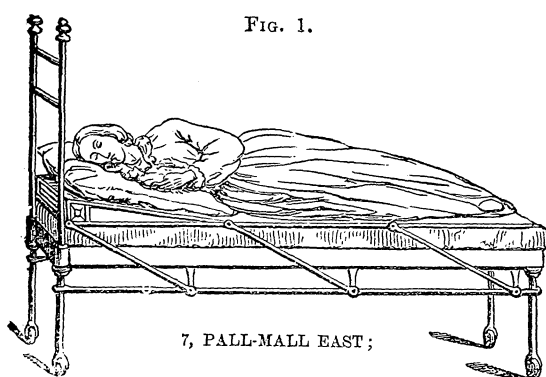

FIG. 1.

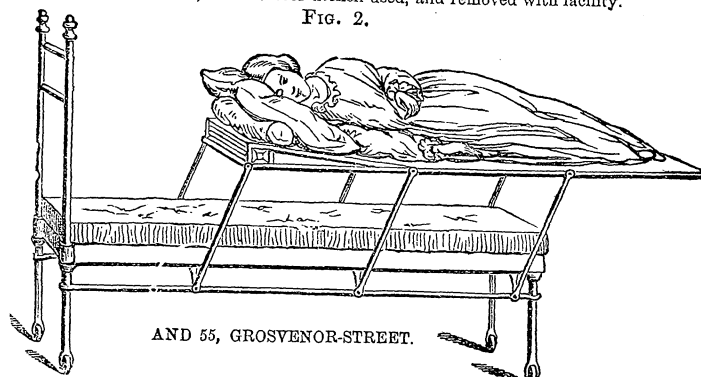

FIG. 2.

7, PALL-MALL EAST;

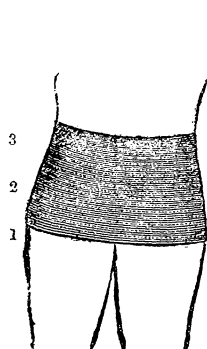

AND 55, GROSVENOR-STREET.

Fig. 1 represents a patient on the Patent Lift Bedstead, the
Lifting Apparatus not being in use.

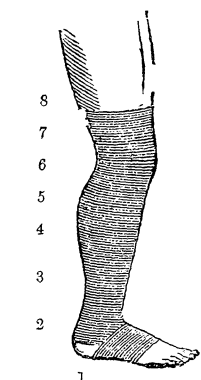

Fig. 2 represents the patient raised up from the ordinary level of the Bed by
means of the Lift, so as to enable the Medical Attendant, or Nurse, to perform
any of the offices before-named.

HOOPER'S SPIRAL ELASTIC SUPPORTERS.

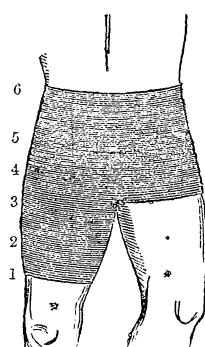

The Figures 1, 2, 3, &c. show the points at which the measures should be taken; the
length should also be stated.

ABDOMINAL UPPTORTER.

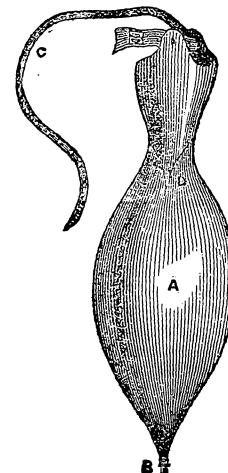

STOCKING ABOVE THE KNEE.

ABDOMINAL SUPPORTER AND
THIGH-PIECE.

HOOPER'S URINALS, WITH VALVE TO PREVENT LEAKAGE,

Constructed of a light porous material, unique in giving continuous and permanent
pressure, can be accurately adjusted, and readily drawn over the parts requiring their
use.

For Invalids, or Railway Travellers; whether Sitting,
Reclining, or Walking; they are not affected by boiling
water, and may, therefore, be easily kept clean.

WATERPROOF SHEETING, FOR PROTECTING BEDDING,

At a great Reduction in Price. It is soft and inodorous, and not acted on by Urine, Acids or Alkalis, and may be washed as
Family Linen.

EXTRACT OF REPORTS from the Medical Department of the Three Presidencies of the Hon. East India Com-
pany; also Reports and Letters from numerous Members of the Medical Profession free by post.

ORIGINAL COMMUNICATIONS.

GLAUCOMA; ITS SYMPTOMS, DIAGNOSIS, AND SURGICAL TREATMENT.

By J. W. HULKE, F.R.C.S.

Assistant-Surgeon to King's College Hospital, and to the Royal London Ophthalmic Hospital.

RATHER more than one year ago, I endeavoured, by an article in this journal, to draw attention to the Surgical treatment of glaucoma by the excision of a portion of the iris (iridectomy), after the manner first suggested and practised by Dr. A. von Graefe, Professor of Ophthalmology in Berlin. At that time the operation had been already fairly tried in the Royal London Ophthalmic Hospital, by Mr. Bowman and Mr. Critchett, and also in private practice, and the results were such as could not fail to convince any unprejudiced mind of the immense value of the proceeding. One might have thought that a measure which so surely offers relief in this most intractable disease, would have been gladly welcomed and generally adopted, had not the annals of medicine shown with what reluctance new truths and discoveries have always been received. It was not to be expected that iridectomy would prove an exception to this general rule; and the past year has shown that during this time it has not gained many new advocates beyond those walls where it was first tried. The number of persons hopelessly blind, but whose sight might have been preserved by iridectomy, is my strong apology for again urging the adoption of this measure in glaucoma; and but for this I should have waited patiently for the recognition of a truth which some years hence will, I believe, be universally admitted.

The extreme differences of opinion respecting the value of iridectomy in glaucoma, expressed by those who have personally tried the operation, have no doubt arisen from the indefinite nature of the cases which have been classed under this denomination, a greenish colour of the pupil having been taken as the distinctive character. The value of any operation in a given class of cases can only be correctly estimated when the character of the cases has been previously fixed and determined; and this has been done for glaucoma by Dr. A. von Graefe, who has so fully and accurately defined its symptoms, that he has left little to subsequent observers but to confirm his statements. He, in common with all Surgeons, recognises two forms of this disease, the chronic, and the acute, which differ in degree but not in kind; between these extremes there is a large proportion of intermediate cases.

Symptoms, Premonitory Period.—In seventy-five per cent. or more both of chronic and acute cases, the more obvious outbreak is preceded by a premonitory period (prodroma), which may be extended over a space of several months, or weeks, or be limited to a few days only; the symptoms are in some cases so slight as hardly to excite attention, and this especially amongst the lower classes, who pay but little heed to trifling ailments. These premonitory symptoms are occasional dimness, with pain in the eyeball, and sometimes headache. They are at first transient, often happen towards evening, and occur at long intervals. Afterwards accessions become more and more frequent, till, at length, the dimness is persistent and the pain chronic; but still with remissions and exacerbations. The subconjunctival veins begin to enlarge and become varicose; the pupil is rather dilated and sluggish, and the globe feels hard. Meanwhile the field of vision has undergone a remarkable contraction, progressing from the periphery towards the centre. Patients still see objects placed directly before them fairly; but cannot see things which lie on one side.

Active Stage of Chronic Glaucoma.—In chronic glaucoma the premonitory merges gradually into the active period. The ciliary region is congested, the radicles of the varicose subconjunctival veins encircle the cornea with arches. The aqueous humour becomes serous, the pupil muddy, and adhesions form between it and the lens. The size of the anterior chamber diminishes, the iris being pushed forwards towards the cornea partly by the lens, and partly by the collection of serum behind it. The cornea loses its lustre, resembles a piece of glass which has been breathed on; its epithelial layer is raised in minute vesicles, and its sensibility

Vol. XL. No. 1036.—NEW SERIES, No. 475.

much impaired. The sclerotic has a dirty leaden hue and staphylomata form, generally just behind the insertions of the tendons of the recti muscles. The globe is now very hard, and sight is limited to bare perception of light or wholly abolished. We must be careful not to be misled on this last point, because luminous spectra often happen long after all sight is lost, and we may be unintentionally deceived by patients reluctant to believe themselves blind.

Acute Glaucoma.—The acute differs from the chronic form mainly by its terrible intensity; it is preceded by the same train of premonitory symptoms; but the outbreak is often so sudden and so violent that the earlier warnings are forgotten in the present storm. The attack often takes place at night. The patient wakes with violent throbbing pain in the eye, intolerable headache and sickness, and rapid blindness ensues. The pupil is widely dilated, fixed, and the globe very red. Patients have not unfrequently ascribed their blindness to a violent attack of bilious headache. After some hours, perhaps, a remission of the symptoms occurs; the pain abates, sight partially returns, and the patient is full of joy at his improvement; but his hopes are soon shattered by a fresh paroxysm. It was only a temporary improvement, and fresh accessions sooner or later bring about total blindness.

Ophthalmoscopic Signs.—The ophthalmoscopic signs of glaucoma are, excavation of the entrance of the optic nerve, the presence of visible pulsation in the retinal vessels, and often hæmorrhagic extravasations into the retinal tissue and vitreous humour. Excavation of the entrance of the optic nerve is indicated by a peculiar bluish tint, and by a very remarkable arrangement of the vessels which are abruptly bent, or seem suddenly to disappear at the margin beyond which they cannot be followed to the centre of the entrance; this is particularly the case with the veins. When the tension of the globe is much increased a visible pulsation in the retinal vessels takes place, and if not present spontaneously a very slight pressure upon the globe with the finger will produce it instantly. The excavation of the optic nerve comes on gradually with the increasing tension of the globe. This part offers less resistance than the tougher sclerotic, and yielding before the excessive intraocular pressure is bulged outwards; a wasting of the nervous fibrils accompanies this important change. From this it will appear that in glaucoma the excavation of the optic nerve is due to two causes, one mechanical, the other vital, pressure and wasting,—the second consequent on the first. Now it has been very recently denied that this change in the shape of the entrance of the optic nerve in glaucoma is ever due to pressure, it being alleged that a degree of pressure which could push the entrance of the optic nerve outwards must necessarily also push the lens and iris forwards, and that extreme excavation of the optic nerve has been observed in cases in which excessive tension does not exist, and in which there is no history of its ever having been present, in which also the anterior chamber preserves its natural dimensions. Such cases do occasionally occur, they were actually described by Graefe in a Memoir on Glaucoma addressed to the French Institute, 1857, and in the "Archiv für Ophthalmologie," Bd. iii. Abth. ii., under the designation of "Amaurosis with excavation of the optic nerve." The morbid anatomy of these cases has been investigated by Heinrich Mueller, and I have myself dissected the hollowed optic nerve-entrances of eyes which certainly at the time of their removal, during life, were not over-tense, and in which over-pressure had probably never been present. In these cases the tubules of the optic nerve have more or less completely disappeared; the surface of the hollow is formed by the membrana limitans (hyaloid membrane) resting upon the connective tissue of the lamina cribrosa and that of the framework, derived from the inner layer of the sheath of the nerve, which separates and supports the bundles of nerve-tubes and which is normally continued upwards as a delicate nucleated fibrous tissue, even through the lamina cribrosa to the hyaloid membrane. This, then, is excavation of the entrance of the optic nerve from wasting and disappearance of its tubules, a change which has occurred without the agency of pressure, but it does not legitimately follow from this that the hollowing out of the entrance of the optic nerve in glaucoma, in which a similar atrophy also occurs, is also independent of pressure. Wasting of a tissue may be induced in several ways, and constant pressure is a most efficient

cause before which the hardest and softest tissues alike disappear.

But over-tension is the leading feature of glaucoma, and it seems only natural to consider the hollowing and wasting of the optic nerve as one of its effects. To these signs, excavation of the optic nerve-entrance, and visible pulsation of the retinal vessels, a third is often added, especially in acute glaucoma. Minute echymoses, points of capillary hæmorrhage appear in the retinal tissue by the rupture of the over-distended capillaries. Often the membrana limitans gives way, and small filmy bloodclots form in the vitreous humour, which becomes tinged with the hæmatine, and in specimens which I have dissected the stain extended to the lens, which had a yellow colour by transmitted light though during life was greenish. Later in the disease the vitreous humour becomes clouded, and the lens and cornea opaque, and the ophthalmoscope can no longer be used.

Prognosis.—The prognosis is allowed by all to be a most unfavourable one. Blindness is the natural termination, and the pain often persists long after sight has been entirely lost,—pain too sometimes of the most wearing kind.

Treatment.—Every candid person must confess that all known Medical treatment fails to cure glaucoma, because it fails to permanently relieve the over-tension of the globe. General antiphlogistic measures are inapplicable, because the subjects are feeble, and local depletion by cupping or leeches affords only very slight and very transient relief. Those who trust to measures of this kind let their patients drift into blindness. But practice has put it beyond doubt that the removal of a portion of the iris of an over-tense eye does permanently lessen the excessive tension, and, therefore, does cure glaucoma. The fact is not to be denied though a satisfactory explanation of its *modus operandi* may be still wanting. For the details of the operation itself, I must refer to a paper in *Medical Times and Gazette*, March 27, 1858. I have nothing more to add to what I then said, except that I believe an ordinary Beer's extraction knife to be a safer instrument for incising the cornea, than the lance-shaped knife of Jaeger, with which, as its point is directed inwards towards the centre of the anterior chamber, and therefore towards the vertex of the lens, there is greater danger of wounding this structure. In about two hundred operations performed with Beer's knife, which in making the corneal wound, only skirts the margin of the anterior chamber, the lens has, I believe, only been injured in three or four cases. In two cases the suspensory ligament gave way, vitreous humour was lost, hæmorrhage into the globe took place, and the eyes suppurated. The immediate effect of the operation is to lessen the tension of the globe; the wound heals in a couple of days, during which the aqueous humour drains away, but when union is quite complete, and the integrity of the anterior chamber is restored, the globe still continues naturally soft. The most complete results are obtained in acute cases, when the improvement of sight is very rapid and striking, and the cessation of pain equally so when the operation has been early performed. In chronic cases the improvement of the sight is gradual, extending over some months; its degree depends on the progress which the structural changes in the retina and optic nerve had made previous to the operation, and in these cases they advance *pari passu* with the growing pressure; but even where the sight is not improved, the operation generally arrests the disease and preserves what sight the patient had at the time of operation. In chronic glaucoma, too, the pain does not always cease at once, but sometimes subsides gradually, just as in tic douloureux it frequently persists for several days after division of the affected nerve.

Alleged objections.—Those who oppose iridectomy in glaucoma do so on the alleged grounds (1) of its futility; (2) of the danger to be apprehended from operating on an eye in a state of intense congestion; (3) of the difficulty of so delicate an operation; for which they would substitute paracentesis of the cornea or sclerotic. These objections are of small value, because they are not founded on practice, from which alone true inferences can be drawn. I will take them seriatim.

1. Facts abundantly prove, that iridectomy does cure this disease. I have been told that patients who had been operated on in the Royal London Ophthalmic Hospital have been afterwards seen at other Hospitals perfectly blind; and, indeed, it would be surprising if this were not the case,

because the operation has been frequently done simply to relieve pain at a time when no restoration of sight could be looked for and no expectation had been held out.

In a few exceptional, very advanced cases of chronic glaucoma, the over-tension of the globe has returned after the operation, and the pain has not been relieved. In these cases the tissues of the globe are so unsound, its vascular system is so completely deranged, and the excitement of the ciliary branches of the fifth nerve has become so habitual, that no measure short of extirpation will afford complete and permanent relief.

2. Practice shows that iridectomy is the most efficient measure with which we are at present acquainted for reducing the intense internal congestion, which is present in acute glaucoma.

3. The difficulties of the operation are not insurmountable; they may be overcome with a little care. They were pointed out in the paper (a) to which I have already referred, and directions were, at the same time, given by which they may be avoided. Less extensive removal of the iris is insufficient; its whole breadth must be taken away so as to expose the edge of the lens and the suspensory ligament. Paracentesis of the cornea affords but an incomplete and transient relief; and it is futile to tap the sclerotic, because the vitreous humour is too firm to flow out, even through a considerable wound.

Lastly, It has been and still is urged that the operation has been very indiscriminately performed. This allegation does not affect the operation itself, but insinuates a want of discrimination on the part of the operator. I would state it in another way—the operation has been experimentally tried in a number of cases, which though not true glaucoma, showed an affinity with it; or where there were local signs of a relative excess of pressure, as in staphylomata of the sclerotic and cornea; and lastly in a few cases of acute phthisis bulbi, where the rapid wasting of the vitreous humour shown by the softness and collapse of the globe indicated a sudden arrest of nutrition.

The results confirmatory of Graefe's statements have proved, that in recurrent iritis and choroido-iritis, where there are numerous synechiæ, the tendency to fresh accessions is lessened and destroyed by iridectomy; that considerable staphylomata subside under its influence; and that soft and collapsing globes become plump and acquire a natural tension. Who then will assert that in these cases the operation has been indiscriminately performed? How can the value and scope of any remedy be ascertained except by a series of experiments? Without these progress would stand still and therapeutics become a stationary art.

ON THE RADICAL CURE OF HERNIA:

WITH AN ACCOUNT OF AN IMPROVED INSTRUMENT, AND NOTES OF FORTY CASES.

By REDFERN DAVIES,

Surgeon to the Birmingham Workhouse Infirmary.

IN cases of scrotal and femoral hernia where the tissues are relaxed and the rings of large size—say, capable of admitting easily two, three, or even more fingers—considerable difficulty and disappointment is experienced in endeavouring to effect a cure by the first operation; and it has occasionally happened to others, and to myself, to be obliged to repeat the process.

From a practical acquaintance with the subject on the living, and repeated trials and experiments upon the bodies of the dead who have been affected with hernia, I have been led to believe that the cause of such failures is not attributable to any fault in the theory of Wutzer's method, but to a defect in his instrument, and upon the following grounds submit to the decision of practical test that they will be obviated by the adoption of the accompanying mechanical improvements in the instrument.

Upon examining a case of scrotal rupture in which the operation for the radical cure has failed (supposing, of course, that it has been properly managed, together with the proper after treatment), the rings and canal will be found to be obliterated probably for some three-fourths of its extent, or there may

(a) *Medical Times and Gazette*, March 27, 1858.

only remain an aperture which will with difficulty admit a crowquill; and thus, though the patient may be greatly benefitted, and with the aid of a truss resume his duties, a radical cure has not been effected.

That portion of the canal and rings which have been blocked up is invariably that which is nearest the abdominal walls. "The gut slips down behind the plug" are the terms in which both Surgeons and patients express the mishap which has occurred, and the reasons for this, I believe, are as follows:—

The anterior or superior layer of the invaginated integument is subjected to not only the pressure of the wooden plug to keep it in apposition with the opposed surface of the rings and canal, but also to the direct pressure of the compressor. The compressor exerts its influence exclusively upon the parts included between it and the upper surface of the said wooden plug, and in no wise affects the posterior parts, viz., the posterior layer of invaginated integument and posterior surface of canal and ring, whose only chance of being kept in apposition depends upon the accuracy with which the plug fits the canal, etc., as a whole.

The floor of the canal, etc., especially where the tissues are lax, as generally occurs in cases of old and large ruptures, does not present in the same manner an opposing resistance to the wooden plug as does the compressor, and thus should the two former be not very accurately adapted the one to the other, adhesion cannot even be expected to occur.

The mouth, or internal opening of the canal, is funnel-shaped, with the posterior surface the more sloped. Consequently, if there be any weak point, it will be there, and it is sure to receive all the shocks of the gut during the process of cure.

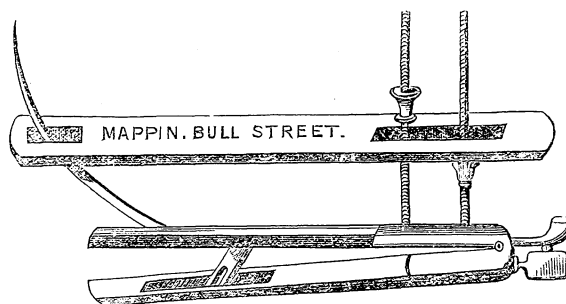

Besides it is evident that a cylinder, even closely applied to the rest of the extent of the canal, cannot fill up its funnel-shaped mouth; but must leave an interspace, which will be on the posterior surface.

And, again, it is not always practicable to introduce to a sufficient extent a solid plug, which would best fit the internal ring, by reason of the resistance of the other structures to its passage, besides entailing an endless variety of such plugs.

By the adoption, however, of the principle I now propose, viz. a plug, whose lower half is capable of expanding, these difficulties are severally overcome.

A glance at the diagram will render its application at once evident: it will be seen that by turning the handle and thus causing the lower half of the plug to expand, that the pressure upon the parts included between the upper portion of

the plug and the compressor, is left in exactly the same condition and relations as in the usual instrument, but that a

force is exerted upon the posterior portions of the invaginated integument, canal and rings, which it gently, but firmly, retains in complete apposition one with the other.

By reason of the greatest point in its expansion being at the extremity of the instrument, and gradually tapering, two objects are accomplished; first, the funnel-shaped mouth, and the internal opening, is filled with a plug, whose sides are inclined towards its own—the invaginated integument being, as it were, modelled upon it; and, secondly, the rest of the canal is at the same time subjected to no undue pressure.

The principle adopted by Mr. Spencer Wells is likewise made available, viz. having the transverse diameter of the instrument very much greater than the antero-posterior, whereby the shape of the ring is altered, it being converted into a mere chink, and thus affording an additional security against descent of the gut; and so leaving as small as possible an amount of space between the opposed surfaces of the *doigt de gant* to fill up when the instrument is removed. A thin India-rubber finger-stall caps the end of the instrument, preventing any soft parts getting between the blades.

By reference to the accompanying table of cases, forty in number, which embraces the three varieties of oblique, ventral, and femoral hernia, occurring in ages varying from one year to sixty-five, and in both sexes, it will be seen that thirty-seven are cured, five requiring the operation to be repeated, and two complete failures (in one of which small-pox appeared on the day after removal of instrument). In this list, however, the more recent cases I have operated upon are not included. They will appear at a subsequent period.

No. of Case.	Variety.	Sex and Age.	Duration and size of Hernia.	Condition of Parts.	Operation.	Length of plug invaginated.	Duration of Instrument.	Results, etc.
1	Oblique inguinal.	Male, 24	3 years; goose egg.	Firm; ring admits one finger.	Wutzer's.	1 6-8ths of an inch.	9 days.	Successful.
2	Ditto.	Male, 24	3 years; pigeon's egg.	Firm; ring admits one finger.	Ditto.	1 4-8ths of an inch.	8 days.	Successful. This man was ruptured on both sides.
3	Ditto.	Male, 1½	Congenital; pigeon's egg.	Very fat; ring admits tip of little finger.	Ditto.	6-8ths of an inch.	5 days.	Successful. The instrument produced remarkably little discomfort.
4	Ditto.	Male, 63	30 years; man's fist.	Relaxed and canal short; ring admits one finger.	Ditto.	1 6-8ths of an inch.	8 days.	Successful.
5	Ditto.	Male, 30	10 years; coconut.	In good condition; ring admits three fingers.	Ditto.	2 inches.	7 days.	Successful in part. When coughing violently the gut descends behind the plug by an aperture the size of a crowquill.
	Ditto.	Same case.	..	Ring admits a crowquill.	Ditto.	1 4-8ths of an inch.	7 days.	Successful.
6	Ditto.	Male, 65	10 years; goose egg.	Relaxed; ring admits one finger.	Ditto.	2 inches.	8 days.	Successful.
7	Ditto.	Male, 20	2 years; hen's egg.	Firm; ring admits two fingers.	Ditto.	1 6-8ths of an inch.	8 days.	Successful.
8	Ditto.	Male, 1	Congenital; pigeon's egg.	Firm; ring admits tip of little finger.	Ditto.	1 inch.	5 days.	Successful.
9	Ditto.	Male, 34	4 years; goose's egg.	Relaxed; ring admits two fingers.	Ditto.	2 2-8ths of an inch.	7 days.	Successful. This patient suffered from retention of urine (without stricture) for two days after application of instrument.
10	Ditto.	Male, 45	10 years; hen's egg.	Firm; ring admits one finger.	Ditto.	1 2-8ths of an inch.	7 days.	Successful.
11	Ditto.	Male, 10	Congenital; hen's egg.	Firm; ring admits one finger.	Ditto.	1 4-8ths of an inch.	4 days.	Successful.
12	Ditto.	Male, 40	14 years; coconut.	Relaxed; ring admits three fingers.	Ditto.	2 4-8ths of an inch.	8 days.	Successful in part; gut descends behind plug. No truss, etc. previously at all restrained the rupture.
	Ditto.	Same case.	Pigeon's egg.	Plug well defined; ring admits little finger.	Ditto.	1 4-8ths of an inch.	7 days.	Successful.
13	Ditto.	Male, 7	Congenital; foetal head.	Relaxed; rings admit two fingers.	Ditto.	1 4-8ths of an inch.	7 days.	Failure. The day after the instrument was removed he was seized with small-pox; no bandage could be applied, and the gut still comes down.

No. of Case.	Variety.	Sex and Age.	Duration and Size of Hernia.	Condition of Parts.	Operation.	Length of plug invaginated.	Duration of Instrument.	Results, etc.
14	Oblique inguinal.	Male, 58	15 year's; goose's egg.	Relaxed; ring admits two fingers.	Wutzer's.	2 inches.	8 days.	Successful.
15	Ditto.	Male, 61	15 years; goose's egg.	Firm; ring admits one finger and a-half.	Ditto.	1 6-8ths of an inch.	8 days.	Successful.
16	Ditto.	Male, 31	6 years; hen's egg.	Firm; ring admits one finger and a-half.	Ditto.	1 4 8ths of an inch.	7 days.	Successful.
17	Ditto.	Male, 48	6 years; hen's egg.	Firm; ring admits two fingers.	Ditto.	1 6-8ths of an inch.	7 days.	Successful.
18	Ditto.	Male, 22	9 years; goose's egg.	Relaxed; ring admits two fingers and a-half.	Ditto.	2 inches.	8 days.	Successful in part; gut gives an impulse without descending into scrotum, which it is feared it will do.
		Same case.	Does not descend into scrotum.	Ring size of a crow-quill.	By a process of invagination by wires.	1 4-8ths of an inch.	6 days.	Successful.
19	Ditto.	Male, 58	20 years; foetal head.	Relaxed; ring admits one finger and a-half.	Wutzer's.	2 inches.	8 days.	Successful.
20	Ditto.	Male, 17	2 years; hen's egg.	Firm; ring admits one finger.	Ditto.	1 4-8ths of an inch.	7 days.	Successful.
21	Ditto.	Male, 21	3 years; goose's egg.	Firm; ring admits two fingers.	Ditto.	1 6-8ths of an inch.	7 days.	Successful.
22	Ditto.	Male, 31	6 months; pigeon's egg.	Firm; ring admits little finger.	By a process of invagination by wires.	1 4-8ths of an inch.	6 days.	Successful.
23	Ditto.	Male, 14	Congenital; hen's egg.	Relaxed; ring admits two fingers.	Wutzer's.	2 inches.	8 days.	Successful.
24	Ditto.	Male, 59	25 years; pigeon's egg.	Relaxed; ring admits one finger; very tender, and testicle atrophied.	Ditto.	1 inch.	7 days.	Successful.
25	Ditto.	Male, 19	2 years; hen's egg.	Firm; ring admits one finger and a-half.	Ditto.	1 4-8ths of an inch.	7 days.	Successful.
26	Ditto.	Male, 59	20 years; foetal head.	Relaxed; ring admits three fingers.	Ditto.	2 inches.	8 days.	Successful in part; gut descends a little behind.
		Same case.	..	Plug clearly felt; ring admits little finger.	Ditto.	1 4-8ths of an inch.	7 days.	Successful.
27	Ditto.	Male, 51	8 years; goose's egg.	Firm; ring admits two fingers.	Ditto.	2 inches.	7 days.	Successful.
28	Ditto.	Male, 35	3 years; hen's egg.	Firm; ring admits one finger.	Ditto.	1 4-8ths of an inch.	7 days.	Successful.
29	Ditto.	Male, 53	10 years; goose's egg.	Relaxed; ring admits two fingers.	Ditto.	2 inches.	8 days.	Successful.
30	Ditto.	Male, 49	3 years; hen's egg.	Firm; ring admits two fingers.	Ditto.	1 6-8ths of an inch.	7 days.	Successful.
31	Ditto.	Female, 9	4 years; pigeon's egg.	Firm; ring would admit a No. 12 catheter.	Ditto.	1 inch.	8 days.	Successful at the time; but from what cause not known gut has again descended.
32	Femoral.	Male, 20	2 years; pigeon's egg.	Firm; femoral ring admits little finger.	Invagination by means of wire.	..	7 days.	Successful. Vide <i>Medical Times and Gazette</i> , Feb. 12, 1859.
33	Ditto.	Female, 4	years; pigeon's egg.	Firm; ring admits little finger.	Same process.	..	6 days.	Successful.
34	Ditto.	Female, 32	3 years; orange.	Firm; ring admits a man's thumb.	Same process.	Successful.
35	Ditto.	Female, 51	20 years; man's head.	Ring admits three fingers; tissues relaxed.	Invagination by plug.	2 1/2 inches.	8 days.	Successful.
36	Ditto.	Female, 50	20 years; man's head.	Ring admits four fingers; tissues relaxed.	Ditto.	2 6-8ths of an inch.	8 days.	Successful in part; to be operated upon again.
37	Ventral.	Male, 26	4 years; pigeon's egg.	Average; ring admits one finger.	By a wire process (vide <i>Med. Times</i> , Feb. 12.)	..	8 days.	Successful.
38	Ditto.	Male, 55	8 years; pigeon's egg.	Relaxed; ring admits one finger.	Ditto.	..	7 days.	Successful.
39	Ditto.	Male, 60	20 years; hen's egg.	Relaxed; ring admits one finger.	Wood's subcutaneous.	..	7 days.	Successful.
40	Ditto.	Female, 18	3 years; walnut.	Firm; ring admits little finger.	Wood's.	..	5 days.	Successful.

REMARKS ON STRICTURE OF THE RECTUM.

By ARMSTRONG TODD, A.B., M.B., M.R.C.S.L.
Surgeon to the Marylebone Dispensary.

THE great difficulty which I have experienced in treating stricture of the rectum has arisen from the annoyance and irritability patients experience when the ordinary bougies are used. This seems to be caused by the anus and sphincter ani muscle being kept extended to the same degree as the bowel and stricture are themselves. The skin and muscle of the anus are much more sensitive than the rectum, and their calibre, even when stretched to the full extent, is much smaller than that of the bowel, therefore a bougie large enough to extend the rectum to its proper size cannot be borne by the anus.

The causes of stricture may be considered to be,—Firstly, a submucous deposit, resulting from inflammation, which becomes of a fibrous character, having a great tendency to

contract. It forms a ring round the mucous membrane, so that any contraction of it must lessen the calibre of the rectum. Secondly, stricture may arise from cicatrization of ulcers; and, Thirdly, from cancerous or other deposits. Over this latter form Surgery has little control. Dilatation in such cases cannot be expected to prove beneficial. In the first two forms, however, I believe perfect cure may be accomplished if proper extension be employed, and if it be continued for a sufficient length of time.

In the first form of stricture the effused lymph, although it appears to have become hard and resisting, yields pretty readily to continued and persevering pressure, and under this treatment it can be caused to absorb, so that a small-sized bougie is in a short time succeeded by a larger one, this again by a still larger, and so on until one of considerable diameter is admitted; but dilatation here becomes limited by the sensitive character of the anus, and the total absorption of the stricture is therefore not effected. If such be the case, although the patient may derive considerable benefit for a time, the contractile propensity of the stricture is, on the discontinuance of the bougies, permitted to proceed, and the

bowel again becomes narrowed. The second form, viz., that produced by cicatrices after ulceration, also yields to the pressure of dilatation; in fact, all contractions of cicatrices, even those resulting from burns, yield to extension made by mechanical contrivances. This has been fully shown by my friend, Mr. Tamplin, who has successfully used this treatment at the Orthopædic Hospital in cases of contracted cicatrices.

In this form of stricture the obstruction does not alone proceed from the cicatrization; there co-exists always some plastic effusion resulting from the inflammation, which taking the fibrous character, I believe, performs a very great, if not the chief part in obstructing the bowel. Thus it is that after ulceration one finds a stricture of considerable tightness, which from simple attention to the general health occasionally becomes resolved without any mechanical treatment whatever. In such cases the effused lymph is reabsorbed before it has taken on that fibrous character which requires dilatation. It is, therefore, unnecessary to interfere with this form of stricture in its early stage, and such practice is frequently injudicious, as any attempt at dilatation may rekindle inflammation. Dilatation, then, seems to be the only means we possess of causing the obliteration of stricture of the rectum; but in order to make sufficient pressure by extension so as to produce complete absorption, it becomes necessary to construct an instrument, which will admit of the rectum being stretched to its full extent, while the anus and sphincter are allowed to remain in their natural contracted state. In all cases dilatation requires to be conducted in a judicious and gradual manner, and, therefore, in the construction of any instrument for dilating purposes this requirement necessitates strict attention.

I subjoin a woodcut of an instrument which has been made from my directions, by Mr. Ferguson, of Giltspur-street.

I have drawn it in a partially extended position, so as to show its action more perfectly. It consists of two blades of finely-polished steel, forming, when closed, a small-sized oval bougie. These blades are about three inches and-a-half long, rounded above and below, and made to separate from and approach each other in a parallel direction, by mechanism contained within. Beneath these is a round stem, quarter of an inch in thickness, upon which the anus and sphincter are allowed to contract. The parallel movement of the blades is effected by four slight bars of steel, placed in pairs—one pair crossing each other above, the other below, united at their intersection by a pivot. The extremities of each pair, at the centre of the blades, are connected together and to the centre of the blades by means of hinges, their distal extremities being permitted to traverse a groove within the blades. The stem before spoken of is hollow, and is continued above, within the blades, into a fork, the extremity of which is attached to the pivot connecting the intersections of the superior crossbars. Through this hollow stem passes a rod, which also ends above in a fork, attached in a similar manner to the pivot through the intersection of the inferior crossbars. The other extremity of this rod is a screw, on which is a graduated scale; to this a thumb-nut is fitted, having a rim on its upper part, which revolves in a groove in the extremity of the outer or hollow stem.

The effect of this mechanism is, that when the nut is turned from right to left, the inner rod is pushed up, and the intersections of the crossbars are made to approximate, the horizontal diagonal of the central quadrangle becomes, therefore, elongated, and thus the blades are separated. A contrary movement of the nut draws down the rod, and brings the blades together. The screw is made so fine, that dilatation can be effected by an exceedingly gradual movement.

This instrument may be found useful in other surgical operations. In dilatation of the vagina, in Lloyd's operation for lithotomy, it would be found advantageous; also in the cure of fissure of the anus by extension. In this affection it

would permit of unctuous applications, or those of solutions of nitrate of silver; or even it might facilitate the division of the fibres of the sphincter. And if the internal mechanism could be made fine enough, it might become applicable to stricture of the urethra, when its parallel expansion would be found very advantageous.

I used this instrument in the case of a lady who had suffered for a very long period from inflammation of the rectum and fistulæ. After the latter had been operated upon, and all became perfectly healed, a stricture, which co-existed with the fistulæ, engaged my attention. Two months having been spent under treatment by bougies, the anus would only admit of one five-eighths of an inch in diameter. On the introduction of the above instrument, almost immediately, by cautious and gradual extension, the stricture was dilated to an inch and-an-eighth, without the least pain or unpleasantness to the patient. She also stated that she could retain the instrument as long as I wished, as it caused no inconvenience whatever.

I may mention a case which came under my care, where the excessive tightness of the stricture compelled me to use a rather rude instrument to dilate it. The result, however, was so decidedly satisfactory, that were I called to a similar case, I should certainly adopt the same course. The instrument I used was a common pair of glove-stretchers. Mrs. W. suffered from inflammation about the anus and rectum, for a period of twelve months. A feeling of delicacy prevented her from applying for surgical aid all this time; but her health becoming considerably impaired, I was at length called to see her. I found a small abscess close to the anus, almost in a bursting condition. This I freely opened, and on further examination I discovered four other fistulæ; having passed the finger into the rectum, I perceived a stricture situated about two-and-a-half inches above the anus, so tight that the point of the forefinger could not penetrate it. The impaired state of the patient's health obliged me immediately to operate upon all the fistulæ, and leave the stricture for after treatment. The operations healed well, and her health became improved, and some weeks having passed over, I commenced the treatment of the stricture by bougies; but I found that although I could pass a small bougie, the anus was so sensitive that it could not be retained even for a few minutes. As she could not be persuaded to continue the treatment, the stricture in time became so tight that a prostatic catheter could not be introduced; and the symptoms assumed so urgent a character, that I felt compelled to divide the stricture with the knife. In order to do this, I constructed a speculum of moderately strong sheet-lead, slit down one side; this I introduced up to the stricture, upon a round wooden plug. The plug being withdrawn, I pressed out the lead with my fingers, so as to dilate the rectum and anus as much as possible; and thus the stricture was fully exposed. I then divided it in three places by submucous sections. This operation, together with the use of bougies, which now could be better borne, gave the patient considerable relief, and she became able to pass the fæces with perfect ease. The largest bougie she could bear was three-quarters of an inch in diameter; this she introduced herself daily for some time after my attendance ceased; but finding herself much relieved, she discontinued the treatment, and in twelve months after the stricture became as bad, if not worse, than ever. On being again called upon, I found that a No. 12 catheter could not be passed through, even with considerable force. Defecation was exceedingly painful and difficult, the fæces coming away like narrow pieces of tape. I now provided, from a common draper's shop, a pair of glove-stretchers. I inserted a short peg into the flat surface of one of the limbs close to the point, and made a corresponding hole in the other, so as to prevent their overlapping each other during introduction into the stricture. Finding the point too thick to be admitted, I was obliged to fine it down considerably. I found this a very efficacious contrivance, for having manipulated with the hand for about ten minutes, as one sees a shopman do when stretching the fingers of a new glove, the stricture became greatly relaxed. I then placed over the handles of the stretchers a number of India-rubber rings, so as to keep up gradual extension, adding a ring now and again, according as the patient could bear them. By this treatment in about an hour I was able to pass my forefinger through the stricture, and the urgent symptoms of the patient were of course relieved.

My change of residence prevented me from following up this case, but she became able to use the stretchers herself, and, I believe, derived great benefit from them.

In this case, in one part of its career, under pressing circumstances, I divided the stricture by three submucous sections, as stated above. This operation has not, I believe, been previously performed. My reason for adopting this mode of proceeding was, that I imagined from the contractile nature of the fibrous structure, each segment would shrink, leaving a space between them; and that with the after employment of efficient dilatation they would become so small as not to interfere with the passage. In the above case I was unable to proceed with the dilatation, as the moment she experienced an ordinary amount of relief she refused further treatment; but from the amount of relief given in so short a time, I believe that under similar circumstances the Surgeon will find this operation facilitate the distention of the stricture, if gentle and continued extension be his after treatment. The submucous division is not so difficult as might be supposed when the lead speculum above detailed is previously introduced. The knife which I used was a small sharp-pointed curved bistoury, which I have frequently employed in operations for strabismus.

16, Old Burlington-street.

CASE OF MELASMA SUPRA-RENALE, OR ADDISON'S DISEASE.

By G. MACKENZIE BACON.

THE following case is of some interest as an illustration of supra-renal disease, according in almost every particular with the instances adduced as types of the disease, in the monograph of the eminent Physician with whose name it is so closely associated. Since the publication of that work several cases have been recorded in which there has been disease of the capsules (and to some extent) without the peculiar bronzing of the skin; but in the present instance the various symptoms seem to have presented themselves in the most orthodox manner, and to have rendered the diagnosis a matter of comparative certainty. It might seem needless to insist on the value of any contribution to pathology, however small, if carefully conducted; but in the case of organs whose functions and morbid changes are involved in almost equal obscurity, such observations acquire a special claim, as it is to pathology alone that we can look for any solid addition to our knowledge on the subject, either by verification or correction of a previous suspicion. The success which has rewarded the researches of one active investigator, should surely, then, be enough to stimulate each to add his mite to the fund of facts, with the certainty that such efforts will, in time, bring a definite increase to our knowledge.

Subjoined are the details of the case, to which I have but to add that I was called to see the patient for the first time a few hours only before his death, and was led to diagnose Addison's disease from the symptoms noted.

John F., aged 15, a well-made lad, of average size, had always had good health till the present illness, which commenced about seven months ago with loss of appetite, nausea, and gradual diminution of strength without any apparent cause. Cachectic sores soon appeared on his thighs and legs, which healed but slowly, and he began to complain of giddiness and pain in the head. These symptoms continued for many weeks, at times being so far mitigated as to induce the boy to attempt a return to his work, which was that of a plasterer; but two or three such attempts only resulted in failure, and on one occasion he fainted on the road, and was brought home by a fellow-labourer. He had medical advice from two or three sources, and was supposed to be much benefited at one time after a long course of treatment. It is worthy of note that his appearance was attributed by his Medical attendants, as well as by his friends, to jaundice; with a view to cure which the latter performed several superstitious rites with great assiduity, one of which consisted in the daily evaporation of a portion of his urine. As soon as a month after his first attack his complexion, from being quite fair, was noticed to have become darker, and his face was of a dirty yellow colour. This increased in intensity

as the end of life approached. During the last week he vomited constantly all he took, and was much troubled with hiccough, became gradually weaker, and died quietly and rather unexpectedly. During the last two days he had anæsthesia of feet and partly of legs, with pain in toes and fingers.

Post-mortem eighteen hours after death.—Rigor mortis well marked. Almost the entire surface of the body, with the exception of the upper portion of the chest, which was of an ordinary flesh colour, was of a dusky olive hue. The face, hands, and legs, were the darkest; but the back, outside of thighs and buttocks, were of a most decided tawny colour; on the face there were patches of a brown colour, and on the front of both knees, and along the course of the spine in the dorsal region were others of two or three inches in extent of a very dark brown. The scrotum was much discoloured, almost black, a change of comparatively recent date, and the penis also but to a less degree. The boy had quite the appearance of a mulatto. The conjunctivæ were quite white and pearly. There was no opportunity of examining the urine, but the amount secreted for the last few days was but small. Body not much wasted. The left supra-renal capsule was rather larger than usual and much altered in character, the distinctions between the various portions quite obliterated. The stroma was pale and flabby, and in it were numerous patches of a firm light yellowish material, having the look of strumous deposits, one nearly as large as a hazel nut. The right capsule was about its normal size, and studded with yellow spots similar to those in its fellow, but not so large—the deposits being evidently of the same nature, but of longer duration and undergoing degeneration. The mesenteric glands were enlarged, but not to any great size. There existed some fine pleuritic adhesions on the right side, but the pulmonary tissue of both lungs was positively healthy, and neither in the kidneys nor elsewhere was there any trace of disease.

The lad's father died of phthisis pulmonalis, as had also other relatives.

The early age at which the disease occurred in this case is worthy of notice.

Norwich.

ELEPHANTIASIS OF THE SCROTUM—OPERATION AND RESULT—WITH REMARKS.

By HAYNES WALTON, F.R.C.S.

Surgeon to St. Mary's and to the Central London Ophthalmic Hospitals.

ELEPHANTIASIS of the scrotum is so rarely seen in this country, and so few operations have been done for it here, that I venture to bring this short and strictly practical communication before the Profession.

In the early part of the year 1847, a gentleman, 29 years old, who had just arrived from the tropics, called on me with enlargement of the whole scrotum, which was doughy, inelastic, and slightly fissured in three or four places. Although the epithelium was much thickened, the general sensibility was not impaired.

The testes were at the upper part of the tumour. The left seemed healthy; the right was a little enlarged and hardened, the effects of a radical cure for hydrocele, that had been accomplished some years ago. The skin at the root of the penis was slightly affected.

The superficial femoral glands on the left side were a little enlarged, and there was a puffiness of the skin in this region. The right groin was quite healthy. Only two years and a-half had the disease been noticed. There were occasional sub-acute inflammatory attacks that seemed to be the growing periods, as the progress was marked on these occasions only.

I recommended an operation. As a matter of course, several opinions were taken, and, so far as I could learn, they did not coincide with my own; and as some of the Surgeons were twice my age, and men of great reputation, it was not to be wondered at that my patient and his friends rejected my advice. Treatment was tried, but the disease progressed, as I learned some years after. Having been overruled by authority, I naturally looked well into the recorded cases of operation for this complaint, and having found that the dangers

were those of hæmorrhage and shock, I determined, if I ever met with any example equally fitting, according to my views, for an operation,—and especially in so early a state, when the causes to be dreaded in a late operation were almost, if not entirely, out of reckoning,—I would operate.

On the 3rd of September last year, a still more favourable case came under my treatment, inasmuch as there was no glandular enlargement, and no puffiness in the skin of either groin.

Mr. C., aged 41, an athletic government quarantine officer, from Barbadoes, arrived in London to seek advice, and was sent to me. His scrotum was about eight or nine pounds' weight. The skin was rough and indurated, and it was redder than in the other instance, but there was the characteristic firm and solid swelling. There was no pain, and no inconvenience beyond that caused by bulk. The integument of the penis was similarly affected. Just four years ago inflammation appeared at the lower part of the scrotum, and, subsiding, left some hardness. Every year there had been several similar attacks, and each had added to the enlargement. Medicines and topical applications had failed in the hands of different practitioners, and it would be a waste of time to enumerate them. The last use of tincture of iodine caused so much suffering, and excited so much inflammation, that no further treatment was allowed, and Mr. C. determined to visit England, in the hope that he might get relieved by surgical operation. I fully explained to my patient that an operation was not devoid of risk; and he assured me that he was prepared to chance an unsuccessful result, rather than submit to the inevitable fate of steady increase of the disease. I also told him that there was just the possibility of my being obliged to remove the testes, to which he assented if I saw need. Under these circumstances, therefore, I determined to operate, and that at once.

The very evident vascularity of the part, added to the known tendency to hæmorrhage, and the difficulty that is generally experienced in checking it, from the rapidity with which the blood flows from scores of apertures, necessarily made me cautious and thoughtful, and I resolved on a plan which served the double purpose of effectually preventing the possibility of untoward bleeding, and enabled me to get the testes completely out of the way, while I was unrestrained in any operative detail.

With the kind assistance of Mr. Henry Smith, of Caroline-street, Mr. Freeman and Mr. Buncombe, of Mile End, I proceeded, on the 30th of September, to operate. Chloroform was used.

The scrotum was raised and pressed on for a few minutes, so as to empty it of as much blood as possible, and then with a long needle, of the sort used by upholsterers, threaded with strong twine, I tied it in small segments close to the trunk, first pushing up the testes, so that they were quite above all that I intended to remove, an act that demanded carefulness, from the indistinctness of these organs. Having had some experience in producing strangulation of a part, I well knew that to be effectual much tightness was needed, and this caution was the more necessary, as I intended to cut close to the nooses, when, without such provision, the divided surfaces would quickly retract away from them. I removed then as much of the scrotum as I could possibly get away. As each strangulated part was liberated, the vessels were secured, and altogether twenty-two ligatures were used. Some of the vessels were larger than I expected, and a few veins bled so freely, that I tied them. The testes fell down to an incredible length, owing to the very great elongation of the spermatic cords. They were healthy, except that the tunica vaginalis of each was much infiltrated. The after-treatment, including the immediate manner of dealing with the wound, had been duly considered, and I had determined that it would be better to amputate as much of the disease as was possible, and to trust to healing by granulation, rather than to attempt to cover the testes by any of the diseased structure. But I changed my plan, and made an attempt, I should rather say an experiment, that succeeded. I pushed up the testes, and forcibly drew together the divided surfaces, and applied sutures. This caused much strain, more than I thought justifiable from preconceived ideas. I then dissected away the thickened integument from the penis. Some prostration followed the operation, and wine and brandy were freely given. There was no secondary hæmorrhage. Contrary to all expectation, the whole wound healed by first

intention, all but an inch and a-half in front, and that failed, I believe, because I removed the sutures from it too soon. I suspected the existence of clots, and I sought in vain for them. But there was not much gaping, so little that no part of the testes was seen. Ultimate closure was readily effected by granulation. The penis also healed over quickly.

Respecting the pathology, it is evident that sub-acute diffuse inflammation of the integuments produced the organic changes.

The morbid anatomy of elephantiasis has long been made out, and a careful examination enabled me to verify the statement of other observers. When the mass was placed in a basin, the bulk was reduced more than half by the exudation of serum. The epidermis was much thickened, but the true skin particularly so. The connective tissue between the scrotum and testis was greatly hypertrophied and intersected with large areolæ. My patient took leave of me, just six weeks after the operation, quite well. The penis was drawn to the right side and rather constricted in the circumference.

I have much pleasure in closing my paper with a report received on March 21. Mr. C. writes:—"My wounds are perfectly well, and the penis is so much better in the hot climate, that the contraction has nearly passed away. I am happy to say that I greatly rejoice at having undergone the operation."

6, Brook-street, Hanover-square.

THE LONDON

PRACTICE OF MEDICINE AND SURGERY.

ST. THOMAS'S HOSPITAL.

CASE OF VESICO-VAGINAL FISTULA TREATED BY OPERATION.

(Under the care of Mr. SIMON.)

[Reported by Mr. THOMAS MORETON, Clinical Assistant.]

Elizabeth G., aged 43, married, has had four children, was admitted into Lydia's Ward, under Mr. Simon's care; states that she has had very difficult labours, requiring instrumental interference, in the first three instances, but never sustained any material injury therefrom. About four and a-half years after her third confinement, she began to have pains at the lower and anterior part of the abdomen, with desire to pass water, but had great difficulty in doing so. The next day she became much worse, and continued to be so for a week, her abdomen increasing in size immensely, and at times was in a state of extreme agony. At the end of this time, on coming out of a warm bath one evening, the pain became unbearable, and a copious gush of water came from the vagina,—about a gallon according to her statement; immediately afterwards the abdomen assumed its natural size, and complete relief from pain followed, during all this time she had been under Medical treatment, but no catheter had been used. Afterwards her urine dribbled away. She again became pregnant; but the child was born dead, and no instruments were employed. On admission she appeared in pretty good condition, but has lost flesh lately; is out of spirits in consequence, undoubtedly, upon her present miserable state, having had incontinence during the last five years. The catamenia have been regular during this time. The urine was examined microscopically, but was found to be healthy; there is no history of vesical calculus. A sound was passed by the urethra into the bladder, and by passing the finger up the vagina, the instrument was felt through the fistula; it was situated high up, close to the anterior lip of the os uteri, and was about half an inch in diameter.

April 7.—This morning the operation was performed. She was placed on her left side, the legs being drawn up, and the pelvis raised. Simpson's speculum having been introduced, a complete ring, including a part of the os uteri was removed from round the fistula; fine silver sutures were introduced, and the aperture was completely and neatly closed. There was very little hæmorrhage. No chloroform was administered. A catheter having been introduced into the bladder, it was fastened there. She was put to bed, and directed to lie on her left side. She had a good deal of pain in uterine region during the rest of the day; was relieved by tinct. opii mxxx. ex. aq. ʒj. statim.

8th.—Feverish, and has considerable pain in the parts.

12th.—Began to menstruate this morning, which is before the proper period.

13th.—Catheter changed.

16th.—Had an enema, which did not relieve the bowels.

21st.—The sutures were this morning removed, and the aperture appeared to be closed.

22nd.—There is still incontinence of urine, depending probably upon the fact that the urethra has not recovered its tone after having had a catheter in it so long.

27th.—Bowels opened by ol. ricini $\mathfrak{z}\text{ij}$, after being confined three weeks.

Before she left the Hospital, which was on May 7, she could retain or pass her water at will; there was a little dribbling, however, at nights.

She again called at the Hospital, about a month after this date, when Mr. Simon made an examination, and found that the fistula was not quite cured; but that there was a small oblique opening passing from before backwards towards the uterus; and she was desired, should the incontinence become troublesome, to again come into the Hospital in order to have the operation repeated.

CHRONIC LARYNGITIS.—SUDDEN ASPHYXIA—TRACHEOTOMY—RECOVERY.

(Under the care of Dr. BARKER.)

The following case is a very good example of a class which one meets with by no means unfrequently, more especially in Hospital practice. We allude to the occurrence of sudden and most alarming symptoms of impending suffocation in the course of chronic laryngitis. Generally the patients give an account of having had syphilis at some remote period. The attack of extreme dyspnoea has usually been preceded for a few days by somewhat increased symptoms of laryngeal obstruction. Then comes the sudden attack. Whether to call it spasm, or to suppose that acute oedema has set in, or to resort to the hypothesis of a displaced and impacted portion of mucus or false membrane, is a puzzle. In the case below it will be seen that the man was walking about the ward but little worse than usual, when suddenly he fell down asphyxiated. Our Hospital reports have contained the narratives of many similar cases during the last few years. However difficult the physical explanation of the attack may be, there is fortunately no doubt about the remedy to be had recourse to. They are the cases which make the best recoveries after tracheotomy. That they are very liable to end fatally if prompt recourse be not had to that measure we have had personal experience from the result of several cases in which, unfortunately, it was not resorted to.

The following narrative of the facts of the case is from the pen of Mr. T. Moreton, Clinical Assistant at the Hospital:—

C. H. S., aged 52, labourer, was admitted into Luke's Ward, May 3, 1859, under the care of Dr. Barker. He states that he has enjoyed good health in general: had syphilis thirty years ago, but certainly never since. About four months ago he caught a cold, and had a very severe cough at the time, which cough disappeared in about a fortnight, but left a hoarseness and tickling sensation in the larynx, and a little dyspnoea: this last symptom was considerably increased occasionally, so that he had paroxysms of extreme dyspnoea. These symptoms have increased of late, which have interfered a good deal with his health. At present he appears to suffer considerably, has a haggard aspect, but no congestion of the face or neck; a little tenderness over the larynx when pressure is made. No dysphagia. The inspirations are prolonged and attended with a wheezing sound, which prevents one from hearing any healthy breathing; but here and there some sonorous rhonchus may be heard. The fauces and soft palate are healthy; sub-maxillary glands are enlarged on both sides, but not extensively; tongue clean and moist; bowels rather confined; pulse 96, small and easily compressed.

Treatment.—Liq. vesicat uterque later laryngis; Pot. iodid gr. v. t. d.; hydr. iod. gr. j. t. d.; pulv. rhei. c. hydr. \mathfrak{z} i. statim.

He continued with very little alteration in any of the above mentioned symptoms until the morning of June 15th, when he appeared to breathe with more difficulty than he had done for some time. He had passed a very uncomfortable night, having been obliged to be in the vertical position; the hoarse sound through larynx considerably increased; face and eyes congested; no delirium. He continued in this state till six

o'clock the same evening, when, while walking across the ward, he fell down almost asphyxiated, face and lips dusky, and the greatest difficulty in breathing. It was deemed necessary to perform the operation of tracheotomy immediately, which was done by Mr. C. H. Drake, the House-Surgeon. There was a little venous hæmorrhage, which was easily stopped by pressure. As soon as the canula was placed in the trachea all congestion disappeared, and he appeared to be very considerably relieved. Wine was given in sufficient quantity; and he slept during the greater part of the night.

16th.—Breathes very easily through the tube. Pulse, 132; full, but easily compressed; respiration, 36; no lividity of face. Ordered,—Liq. ammon. acet. $\mathfrak{z}\text{ij}$, vin. ant. pot. tart. $\text{m}\mathfrak{x}$., sp. nit. æth. $\mathfrak{z}\text{ss}$., 4tis horis, c. mist. camph.

17th.—There does not appear to be any disease of the lungs yet. Pulse, 124; respiration, 36; sleeps well.

18th.—Pulse 116; respiration, 32; thirstiness, lemonade and beef-tea.

20th.—Complains of pain in the back, and on examining the right lung posteriorly, there is found complete dullness extending half-way up the chest; a blowing sound is heard on respiration, and some crepitation at the lowest part. Respiration 36; pulse 112. Ordered,—Pil. hydr. gr. v., opii gr. $\frac{1}{2}$, t. d.; liq. ammon. acet. $\mathfrak{z}\text{ss}$., sp. æth. nit. $\mathfrak{z}\text{j}$, tinct. hyoscy. $\text{m}\mathfrak{x}\mathfrak{x}$., 4tis horis, c. mist. camph. Emp. canth. lat. dext. Canula removed.

21st.—No change in the thoracic symptoms; expectoration is rather puriform. Ordered,—Wine $\mathfrak{z}\text{ij}$, two eggs.

22nd.—A little blood mixed with the expectoration.

24th.—The dullness is gradually disappearing, and the respiration is not so quickly performed.

From this date he continued to improve gradually; cough, etc., ceased, and he left the Hospital, July 15, in perfect health, with the exception of slight hoarseness, the artificial wound being completely closed.

THE PROVINCIAL PRACTICE OF MEDICINE AND SURGERY.

THE HULL INFIRMARY.

OVARIAN DROPSY—PARACENTESIS UNDER URGENT CIRCUMSTANCES—DEATH SIX MONTHS AFTERWARDS—AUTOPSY.

(Under the care of Dr. LUNN.)

The following case, for the full notes of which we are indebted to Mr. Evans, the House Surgeon to the Hull Infirmary, has some points of interest in reference to the recent revival of Ovariectomy. It illustrates, at any rate, what is but too often witnessed, the very transitory nature of the relief afforded by paracentesis.

Elizabeth B., a married woman aged 58, was admitted under the care of Dr. Lunn on January 28, 1859. She had previously been under care in June 1858, and had received some benefit from the employment of diuretics. She was the subject of ovarian dropsy on the left side, and the tumour had first been noticed six years ago. The circumference of the abdomen was nearly forty-eight inches, and the integuments were very tense. The lower limbs were oedematous, her dyspnoea was great, and she had partial incontinence of urine. Under these urgent circumstances paracentesis was adopted, for the first time, about a week after her admission. The fluctuation wave had been so distinctly felt passing from side to side, that before the operation, the tumour was thought to be unilocular.

The tapping, however, proved that it consisted of several cysts. About three gallons of fluid were removed, and a considerable mass still remained in the abdomen. When three days afterwards the abdomen was again measured, it was found to be only six inches less in circumference than before the tapping.

The paracentesis was well borne, and the woman regained her health; she left the Hospital at her own wish two months afterwards.

After remaining about two months at home, the woman was re-admitted in a state of extreme debility and emaciation,

on June 15, 1859. From her own account, it appeared that a week or two before, her abdomen had given way, and several pints of fluid had escaped. Four days after her readmission, death relieved her of her sufferings. Her condition throughout this period had been too low to permit of any operative interference.

The autopsy was performed twelve hours after death, and was conducted with especial relation to the question, as to whether or not the tumour might have been removed with a fair chance of safety during life. The peritoneum in front of the abdomen was found to be thickened, and was adherent extensively and firmly to the anterior surface of the tumour. The latter filled the whole abdominal cavity. On its surface was a quantity of recent lymph, and surrounding it was a considerable amount of ascitic fluid. The tumour was without difficulty turned out of the abdomen, its adhesions to parts behind being very slight. It was multilocular, and involved the left ovary. The abdominal viscera were pushed up under the ribs, and covered in by a coating of lymph. The tumour after removal weighed eighteen pounds.

With regard to the evidences of extensive recent peritoneal inflammation, it may be remarked that the woman had only occasionally complained of a little pain. It was probably to the depressing influence of this masked peritonitis that death was immediately due. Most ovariologists agree, we believe, in considering anterior adhesions of but little consequence, and regard the case as favourable, so long as the tumour is not connected to any viscera, and does not adhere to parts behind.

THE COLONIAL PRACTICE OF MEDICINE AND SURGERY.

SYDNEY HOSPITAL, NEW SOUTH WALES.

ACUTE PHLEGMONOUS INFLAMMATION. DESTRUCTION OF KNEE-JOINT.

(Communicated by Mr. ALFRED ROBERTS.)

R. U., aged 40 years, admitted into Sydney Hospital, September 5th, 1858. A sawyer by trade. Is an Englishman, and possesses a sound constitution. At Christmas last he accidentally discovered that his right knee was about half as large again as natural; it was free from pain. He applied to a chemist, and received a blister and liniment. No other treatment was adopted, and he continued at work, walking daily a mile and a half to and from his house over heavy hills. On Friday, August 31st, went to work as usual, feeling well. In a couple of hours he experienced cold shivers and excruciating pain in knee. He walked home with great difficulty, and found his knee much enlarged. A chemist only was again applied to, who did nothing. On following Monday night the leg and thigh suddenly swelled to double their natural size; the patient's mind wandered, and fever ranged high, still no treatment was adopted, and attendants say no change occurred until Wednesday evening, when he was brought to the Hospital. I then visited him, and found him in a lamentable state. His leg and thigh presented the severest example of *acute* (if I may say so) phlegmonous erysipelas I ever witnessed. The knee-joint, I feared, had gone, and there was intense constitutional disturbance. Under careful nursing, feeding, and care, his symptoms at first yielded; but in about ten days (on the 22nd) I found his *only* chance of life was to remove the limb, which I did, as he lay upon the water-bed, and without the administration of chloroform. The operation was very rapidly performed, and thanks to my colleagues scarcely a couple of ounces of blood were lost. His pulse improved during and after the operation, but he eventually sank.

My reason for stating the brief outline of this case as above, is, that I conceive it to have been one of acute inflammation of the knee-joint, excited by the violent exercise of a joint already in a subacute state of disease. The acute symptoms ran on unchecked by treatment, and in their turn engendered acute phlegmonous erysipelas, and this also ran its course through its first destructive stage, for upon his arrival at the Hospital, there was nothing to be done but support the system and give exit to the effused liquor sanguinis and pus. It is

seldom that so fearful a disease as acute inflammation of the knee-joint is allowed to run its course unchecked in a strong and robust man, and, as such, it appeared to me worthy of record. On September 10 the articular surfaces of femur and tibia were distinctly felt to grate freely together, and three days after the ligaments had evidently given way. I cannot call to mind any patient whose constitution fought so strongly against such an amount of disease, neither do I imagine it could have done so in any London Hospital: the powers of nature in recovering from severe shocks and illness are very striking in this climate.

ANEURISM OF FEMORAL ARTERY—LIGATURE—AMPUTATION—RECOVERY.

(Communicated by Mr. ALFRED ROBERTS.)

R. B. aged 35 years, admitted into Sydney Hospital April 10, 1855. Is a native of South America; about five feet eight inches high, well proportioned and moderately robust. States that he is a musician, travelling with a circus, riding in the bush at times for days together; has drank freely for three years; is naturally passionate, but does not recollect injuring his leg at any time lately; has suffered slightly from hæmorrhoids. About three months since observed a small swelling behind, and rather to inner side, of left knee, to which under a variety of advice, different remedies were applied (consisting of warm fomentations, blisters, and liniments) without relief. The swelling increased rapidly, and he came to Sydney on horseback, a distance of about 150 miles. Present symptoms—Large and very tense swelling in region and direction of tendinous canal, embracing three-fifths of lower thigh. Careful examination could not detect pulsation; considerable heat; great pain, with constitutional febrile irritation. Ordered to remain quiet in bed with limb elevated. Haust. salin. sextis horis.

April 27.—Tension of tumour greatly increased; upper portion more rounded and prominent; no pulsation; much irritation, fever, and anxiety. He was placed upon the operating-table, and tumour explored with fine exploring trocar. Arterial blood flowed freely. The femoral artery was immediately ligatured low down in its course under the sartorius, and the patient put to bed.

30th.—Tumour very slightly reduced; neither more flaccid or solid; rather less painful; constitutional symptoms the same.

May 4.—A patch of sphacelus about the size of a fourpenny piece has made its appearance around the puncture of the tumour. The tissues here have been gradually getting thinner. Amputation was performed at middle of thigh, the flaps being made antero-external and postero-internal to bring the former incision into that made in forming them. As might be expected, several vessels required ligature. He made a good recovery.

Examination of the limb showed the artery abruptly opening into a large cavity, about an inch below its entrance into the tendinous canal. The portion of the cyst nearest to and adjoining the entrance of the artery is evidently continuous with it; the more distant portion is apparently composed of condensed cellular tissue. The cavity is three-fifths filled with a fibrinous mass, the remaining two-fifths with coagula in various stages of decomposition. The rounded form of inferior and upper portions is well marked, and at the entrance of the artery into the cavity a sharp edge of fibrinous mass projects three-sixteenths of an inch into the diameter of the vessel. Decomposed blood is effused into the cellular tissue for some inches around the sphacelic notch and into the intermuscular spaces of the upper part of leg.

The following remarks made at the time are extracted from my private note-book, and serve simply to give my thoughts upon this rather interesting case:—

This case appears to have been one of aneurism of femoral artery occurring in the somewhat unusual position of its tendinous sheath. Its peculiar form of an irregular oval is accounted for by this circumstance, but the rounded form of the superior part was peculiar. As it increased in size, it appears to have put aside the vastus internus, and it acquired its greatest prominence about three inches above and to inner side of inner edge of patella. It would seem from the history and dissection that up to the time of the man's coming to Sydney on horseback nature had been active in her endeavours to cure the disease, and the progress made warrants the conclusion, that, under favourable circumstances, she would in

this case have been successful. (Query. How far could this have been brought about by the firm pressure of the tendinous sheath?) The projection of the fibrinous mass into the calibre of the entrance of the vessel was well marked, and is worthy of thought. The operation was simple and straightforward; but many vessels required ligature, among them the femoral, the section being an inch below the former ligature. The silk from the extremity of femoral was the last to come away. The stump was an excellent one a year after the operation. I presume the aneurismal sac gave way during the journey to Sydney on horseback.

Medical Times & Gazette.

SATURDAY, AUGUST 6.

THE MEDICAL COUNCIL.

THE General Council of Medical Education and Registration inaugurated its second sitting on Wednesday, and proceeded to the dispatch of business. Constituted as it is of representatives from the various Medical and Surgical Institutions of the country, the Medical Council thus assembled may be looked upon as the Parliament of the Profession, and its proceedings must be regarded with great interest, as exercising an important influence on the welfare of Medical Practitioners, and secondarily on the public weal.

The duties of the Medical Council, as indicated by its appellation, and by the scope of the Medical Act, naturally arrange themselves under two divisions: 1st, the Registration of all legally-qualified Practitioners; and 2ndly, Medical Education.

The sitting of October last was chiefly occupied by preliminary matters, and in preparing the machinery for an efficient registration. An executive committee was appointed to carry out the provisions of the Act in this respect, and as the result we have the recent publication of the Medical Register. This much being achieved, the General Council has this year to turn its attention to the second division of its duties, the still more important question of Medical education and examination. That the latter is the more important question we think must be admitted, as upon the efficient education and intelligence of the Medical attendant necessarily depend the social position he holds as a unit of the general community in which he may be placed, and in proportion to the excellence of qualifications possessed by Medical men in their collective capacity will their services be valuable to the state. We are sensible that the educational question is difficult to approach. With such diverse opinions and interests, the Medical Council have a complex knot to untie, requiring careful consideration, and not a little forbearance in addition. The requirements of candidates by the different examining bodies have hitherto been so unequal, and the opinions held by authorities as to the extent of qualifications to be demanded of candidates are so various, that if each finds its champion in Council, much time will be wasted, and no useful regulations will result.

It is obvious, from the entire construction of the Act, that the purpose of the Legislature was to establish uniformity of privilege, combined with uniformity of qualification. The General Medical Council is empowered from time to time to demand the regulations in force from the various examining bodies; and the regulations of all have, we believe, been submitted at this meeting for the consideration of the Council. Besides this, any members of the Council, or any person deputed by the Council, may be present during the examinations, with a view to test their efficiency. While, therefore, the General Council has no power to interfere with the independence of any University or College, if its regulations are, in the opinion of the Council, inadequate to secure the requisite knowledge and skill for efficient Medical practice, the College or University may be reported to the Privy Council, and suspended until the demands of the Council are satisfied. This being the indirect way in which the power of the Medical Council is made to bear on the licensing bodies, we are induced to think that the Council must fix a minimum standard as a line of demarcation, below which no examining body must be allowed to sink its education and examination without endangering a suspension of its licensing powers. A competition downwards, hitherto much complained of, will thus be effectually stopped, and a competition upwards only be permitted. Thus while the danger will be removed of any Body passing incompetent men, an emulative spirit will be fostered among the examining bodies, and they will soon learn, that in proportion to the excellence of their reputation, so will applicants for their diplomas become more numerous, and the confidence of the public in their licentiates be the greater. The first point which we would suggest as necessary to engage the attention of the Council, is the satisfactory preliminary education of all candidates for the Medical Profession. The impression has firmly gained ground that a Medical attendant, to take his proper position in Society as an educated scientific man, must know something else besides the mere routine of Medical practice, and he must have a competent knowledge of general literature and science. It is a liberal education which can alone be expected to foster broad and extended views of Medicine as a science, and by exterminating narrow and imperfect considerations, prevent the passing into such deplorable heresies as those into which some of our brethren have unluckily fallen. Some of the examining bodies have already taken the initiative in this matter, but until very lately it has rather been the rule to include subjects which should have been part of a preliminary examination in the professional one, and the result has been great inconvenience to the student from the multiplicity of subjects requiring his attention, and generally an imperfect knowledge of all. Were all students submitted to a fair preliminary examination before being allowed to commence Medical studies, a great incubus would be removed from their shoulders in the last years of studentship, and they might reasonably be supposed to do more ample justice to both classes of subjects.

As to the best means of securing a good minimum standard of Professional qualifications, much discussion may be expected to arise. Some will doubtless hold that examinations afford no reliable criterion of the merits of candidates, and that it is only by a carefully-regulated course of Professional study from the very commencement that any guarantee is afforded of competency. Others, again, content to leave to the discretion of candidates the way in which knowledge is to be obtained, will trust solely to the appearance they make at an examination. We believe that safety is to be found in a combination of both these opinions—careful education and stringent examination together. In Anatomy, Chemistry, and the like, a sifting examination would probably gauge most accurately the acquirements of a candidate; but we question much if the same can be affirmed of Medicine,

Surgery, or Midwifery. A student well "ground up" might pass the best possible examination written and aural in these subjects, and yet be very much at a loss when at the bedside of a patient. This difficulty has been fully recognised by some examining bodies, and, in addition to prescribed Hospital practice, attempts have been made to examine in Medicine at the bedside of the patient; but this could not so readily be carried out for Surgery or Midwifery.

The Universities of London and of St. Andrews (to their honour be it spoken) have been among the first to institute for their degree a Medical examination at the bedside of the patient; but the London College of Physicians, true to its traditions, and unwilling to countenance so great an innovation, refused to sanction a proposal of a similar kind, brought forward by some of its Fellows. Medical examinations, however, to be at all useful, must not be instituted only at the termination of the course of study—this favours merely the interests of the "grinder"—but they should be frequently repeated throughout the curriculum, the student in this way being obliged to make use of his time, and not delay serious work until the last few weeks or months before the one and only ordeal. An examination conducted at the end of every Medical session would be a constant inducement to steady application, and would furnish a fairer test of competency than a single and concluding examination.

As to the manner in which information on Medical subjects is best inculcated to students, we must have teachers of experience to decide. Sir Astley Cooper openly expressed his conviction, that no benefit resulted to the student from attendance on lectures; and it has become somewhat the habit, among admirers of his, to echo the same opinion. If the Professor is at all equal to his subject, however, there can be no doubt that the lecture is a most useful means of communicating knowledge; and it is to be borne in mind that most courses of lectures are now very different to what they were in former days—being much more of the nature of demonstrations, and impressing the mind more strongly than any amount of reading on the same subject. That students are very much over-lectured on some subjects, and too little on others, is most probably true; and it may also be true that no good results from the certificate system. Diligent students will generally attend the lectures of him who has the faculty and will take the pains properly to teach them, whether certificates of regular attendance be required or not. But what benefit can result from the compulsory attendance on two or three courses of lectures on the same subject, and perhaps nearly in the same words, might, perhaps, even puzzle the ingenuity of the lecturer who reaps the benefit to explain.

Whatever opinions are held as to the propriety of compulsory attendance on lectures, all agree in recommending a diligent attendance on the Medical and Surgical practice in a public Hospital. Could this be ensured, in addition to periodical examinations, probably all the elements would be present for creating sound Practitioners; and any method of improving clinical instruction should be regarded as of the greatest moment.

We trust that the Medical Council will not be led aside by any old traditions or present prejudices; but, giving ample scope to any aspirations on the part of the examining bodies, it will take care that none give partial and inefficient examinations. We would especially remark that Midwifery should be embodied in the general examinations of both Medical and Surgical colleges, which would abrogate the necessity of a special licence in Midwifery. The latter is objectionable, not only because it increases the number of qualifications, and is derogatory to the position of the Obstetric Practitioner; but, also, because it furnishes a pretext for omitting the subject from the general examination, and may thus allow persons to practise who have never afforded any proof of proper qualification in this department.

THE WEEK.

THE Council of the Royal College of Physicians of Edinburgh have thought it necessary to allay what they call "certain misconceptions and misrepresentations extensively prevalent, relative to the recent creation of Licentiates by the College," by the publication of an "Explanatory Minute." The document is lengthy; and we are bound to add rather of an apologetic than explanatory character. It appears clear from the statements made in this document, that not one of the objections taken by us in reference to the proceedings of the College in this matter, was taken without justification. This is highly satisfactory to ourselves. We shall again refer to this document, which has only just come into our hands; on the present occasion, we shall merely notice what the College has to say, "explanatory," concerning the question "Who is a Doctor?"

The Council say:—"That nothing can be more groundless than the charge that the College has issued its Licence to practise in a way calculated to lead to the assumption of the title of Doctor by persons having no claim to it." Now we have shown, and it has never been denied, that at least 95 per cent. of those gentlemen who have taken this licence are Englishmen; and that not possessing the title of *Doctor Medicina* from any University, they take this licence for the very purpose, and with the best intention, of calling themselves "Doctors;" that, in fact, such gentlemen having got the licence do, on the strength of its possession, actually at this moment call themselves Doctors. No one ever pretended that the Edinburgh College had claimed the power of conferring the title of Doctor. All that was objected to the College was this simple fact,—*That the College is at this moment, through its Licence, raising up in England a large body of Practitioners, who call themselves Doctors;* and that the College carefully avoids any expression of opinion contrary to the right of assuming such title.

This was all that has hitherto been objected. But now the College, in its apology, steps out a little further, and, if we are not vastly mistaken, does really and truly by inference justify its Licentiates in taking to themselves this title; and condemns itself of the accusation from which it pretends to purge itself. We quote the paragraph at length to prevent any mistake; and we venture to say that all the recently-made Licentiates of the College, who have taken this title of Doctor, will now consider themselves backed therein by their Alma Mater.

"It may be a subject for discussion, by what conventional name the Licentiate of a College of Physicians is hereafter to be known. The College has not endeavoured to prejudge this question. The Council cannot be surprised that the power of conferring the title of 'Doctor' should be claimed as an exclusive right by the Universities, any more than that the practice of the College of Physicians of London should have appeared to some of the Edinburgh Licentiates to justify them in assuming a title of courtesy, which undoubtedly is in fact employed with very little reserve. On the other hand, the designation of 'Physician' is still understood by many as one not applicable to the General Practitioner. It is quite certain, however, that some name must be found for non-graduated Licentiates of a College of Physicians, shorter, and more conveniently distinctive, than their legal designation; and if it is not formally arranged by the Colleges what that name is to be, the public and the profession will take the matter into their own hands, and will establish an usage overriding all formal objections that may be taken to the employment of one or other of these conventional titles."

This paragraph we recommend to the careful attention of every new Licentiate of the Edinburgh College. We fancy he will here find all he wants, broadly hinted, though carefully veiled under the shadow of an obscure though not unskilful verbosity.

We have to record another conviction under the Medical Act. Mr. Bradley, Chemist, appeared before the bench of magistrates at Brighton, on the 27th July, to answer a summons for that he did "wilfully and falsely pretend to be, or take, or use the title Physician, etc.;" and it was shown by the evidence that he had occupied his present shop ten or twelve months, that over the window was written "son of the late Dr. Bradley," the words "Dr. Bradley" being written in large characters, the others in small, so as scarcely to be seen by daylight. The Medical Register was produced to prove that he had not registered his name. After a short deliberation, the chairman said that he and his brother magistrates were of opinion that this was exactly one of the cases which the Act was intended to meet. They had no doubt that the name was put up to hold out to the public that a "Dr. Bradley" was there; but as they were of opinion that it was put up before the Act came into operation, and as this was the first case, they would mitigate the fine to 20s. The defendant might alter the "D" into "M." In another case where the defendant used the word "Dr.," with the addition "M.B.," meaning Medical Botanist, over his shop-window, the defendant undertook to remove the "Dr." and to discontinue the use of the objectionable initials, in consequence of which the case was not gone into.

The cholera is again here, and it has arrived by the old route, from Hamburg. One case proved fatal last week on board one of the Hamburg steamers on her passage; another was sent to the *Dreadnought* and died there, also from a Hamburg vessel; and a third died in a Hamburg vessel on the Thames. Dr. McWilliam, who is doing duty temporarily for Sir Wm. Pym, the Superintendent-General of Quarantine, has done all that he is empowered to do by having vessels from Hamburg boarded at Gravesend, and suspicious cases of disease removed to the *Dreadnought*, or elsewhere, and similar instructions have been sent to our eastern and north-eastern ports; but beyond this the Privy Council will not act. The mischief is probably done by this time, and we are not likely to escape an autumn epidemic of cholera; but we have a strong conviction that it would be well to keep all vessels arriving in England from Hamburg, or from any port infected with cholera, under observation for at least three days before admitting their passengers to land in this country. This could lead to no very great inconvenience or loss, and it would surely be better to err on the side of excessive caution than of culpable neglect.

Mr. Pullin, of Sidmouth, has made out a strong case against the Poor-law Guardians of his Union. It appears that he has been guilty of a very heinous offence—he has been "too lavish in ordering nourishing things for the poor"—and has been dismissed from his office. He complained to the Poor-law Board; but that great central authority simply denied that he had been dismissed. "His year of office had simply expired, and another Medical Officer was appointed in his place. It was no dismissal, but a lapse of the engagement." The answer to this is, that the engagement, though annual, was always renewed without notice. Mr. Pullin justly complains of the insulting subjection to the reports of a non-medical and subordinate officer as to his dietetic treatment of the sick poor; and we trust that a further exposure of the case may induce the Poor-law Board to reconsider their decision.

The British Medical Association last week held the twenty-seventh annual meeting in Liverpool, where the Members assembled once before, twenty years ago. The meeting has

been of the most complete and satisfactory kind. Every thing that it was possible to do to render the visit of the Associates agreeable was done by the authorities of the town, and by the Local Committee of the Association. In all the arrangements made the most liberal measures were taken to ensure success. Nearly two hundred of the Associates were present, among whom were comprised many of the leading Members of the Association. The meetings were held at the Medical Institution, Mount Pleasant. A short account of the proceedings will be found in another column. The old story is retold. The Association is kept in perpetual difficulty by the expenditure on the *Journal*, and extra subscriptions are called for to discharge the debt; while the Association is unable to advance Medical Science by incurring any expense in scientific inquiries, or by the publication of such volumes of Transactions as might be looked for from so numerous and intelligent a body of workers.

On June 12, 1852, two Medical men, residing in Edinburgh, signed the following certificate:—"We, George Glover, Surgeon, and Thomas G. Weir, Esq. M.D., hereby solemnly declare on soul and conscience, that from our own personal observation, and from the report of creditable witnesses, we believe Angus Mackintosh, of Holm, to be in such a state of mental derangement as to require confinement in an asylum." Under this certificate, and by virtue of the usual Sheriff's warrant, Mr. Mackintosh was removed to a private asylum, where he was detained until the 21st of July following, when he made his escape, from which time he has been allowed to go at liberty, and has managed his own affairs, without interference. Mr. Mackintosh, feeling aggrieved by these proceedings, lately commenced an action in the Court of Session in Scotland, against Mr. Fraser, the law agent by whom the Sheriff's warrant was obtained, and against Mr. Glover and Dr. Weir to recover damages to the amount of £10,000 for the loss, injury, and damage sustained by him in his credit, character, and reputation, in consequence of his wrongful detention in the asylum. In this action two issues were directed, one referring to Mr. Fraser, the other to Mr. Glover and Dr. Weir. The latter was, "Whether, on or about June 12, 1852, George Glover and Thomas Graham Weir, did wrongfully and without due inquiry and examination, grant the above certificate, the pursuer, Angus Mackintosh, not being then insane, nor in such a state of mental derangement as to require confinement in a lunatic asylum to the loss, injury, and damage of the pursuer." The trial came on before the Lord President of the Court of Session and a jury, at Edinburgh, on July 25, and terminated on the 28th, by the following verdict:—"The jury is unanimously of opinion that the pursuer was insane on the 12th day of June, 1852, and that he was justifiably sent to and confined in the asylum. The jury, therefore, finds for the defenders on both issues." In charging the jury the Lord President remarked that there were certain points which must be established by the pursuer in order to entitle him to a verdict. First, they must be satisfied that at the time about which they were inquiring the pursuer was not insane; but, second, although he might not have been insane, it was incumbent on him to show that the defendants acted wrongfully. Taking first the issue referring to the Medical men, the question was, whether they granted that certificate, the pursuer not being insane, nor in such a state of mental derangement as to require confinement in a lunatic asylum, and whether they granted it wrongfully. If they were in the full belief, in the exercise of their skill and judgment, that the pursuer was in a state of insanity; if they proceeded with due deliberation, and made due inquiry, then there was no wrong done; but if they were not qualified practitioners, if they knew the pursuer not to be insane, or if they made no examination of him at all, but

granted the certificate at haphazard, that would be wrong. If they did not apply their minds to the question of whether he was insane or not, but at the solicitation of some person granted the certificate without having formed any opinion at all; and if the certificate led to the confinement of a sane man, then that was wrong. But if they, being qualified practitioners, applied their minds to the case, and proceeded with fair caution and acted in good faith, that was all that the law required, in order to their protection. The best of men might be mistaken, and upon subjects such as this there might exist differences of opinion; but the mere circumstance that other people might be found to express a different opinion was not enough to subject in damages those persons who, with a due knowledge of their profession, acted honestly, and applied their minds faithfully to the consideration of the case, and gave a certificate upon soul and conscience to the best of their judgment and skill. Medical men had professional as well as social duties to perform; and he would be a strange member of his profession, if, when his professional services were required for the immediate safety of any individual, whether in a case of insanity or any case of disease, he should withhold his assistance and advice. It was, therefore, necessary in such cases that the jury should proceed cautiously, and that persons exercising those functions for the interests of the community should not be deterred from the exercise of them by an unfair consideration of the circumstances under which they were exercised, and that society should not be deprived of the benefit of their advice when its exigencies required it, for the proper prosecution of the law or the safety of individuals. On the other hand, if they acted illegally, and without good faith, and if they disregarded the proper considerations which ought to guide professional men, they were not entitled to ask the protection of the law.

BRITISH MEDICAL ASSOCIATION.

THE twenty-seventh annual meeting of this Association took place at Liverpool last week. The following is a short outline of the proceedings:—

WEDNESDAY, July 27.—Meetings of Committee of Medical Legislation, Committee of Council, and of General Council, morning and afternoon; and in the evening the first general meeting of the Association, with the addresses of the retiring President and new President, the presentation of the report of Council, etc.

THURSDAY, July 28.—Public breakfast; meeting of members of New Council; second general meeting of members, with the address in Medicine, papers, and cases, and report of the Benevolent Fund; in the evening, *soirée* at the Royal Institution.

FRIDAY, July 29.—Third general meeting of members; the address in physiology, with papers and cases; excursion by steamer in afternoon, and dinner in the evening.

The space at our disposal only enables us to give a short account of the principal proceedings of each day.

At the first general meeting, on Wednesday evening, Sir CHARLES HASTINGS apologised for the absence of Professor Alison, the retiring President, and Dr. Vose, the new President, read his address. He welcomed the members to Liverpool, gave a short sketch of the medical history and notabilities of the town, and alluded to the principal events of the past year interesting to the Profession—as the passing of the Medical Act, Jenner's statue, Hunter's re-interment, etc., and concluded an eloquent address by some remarks on the claims of the profession to public estimation.

Dr. WILLIAMS read the annual report, from which it appeared that, since the commencement of the year, 200 names had been added to the list of subscribers. There had been 60 resignations, and 30 deaths, making the total number of subscribers 2310. The receipts for the year 1856 had been £2435 17s. 1d.; the expenditure, £2729 7s. 2½d., leaving a balance due to the treasurer of £293 10s. 1½d. The report went on to say:—"Your council beg to call the attention of

the members to the financial statement, and to remind them that, in the year 1856, there was a debt due by this body which amounted to nearly £2000. By the call of 10s. then made, and by the fact of the income having since that time exceeded our expenditure, that debt has been very considerably diminished; but this diminution is going on slowly, and inconvenience results from the treasurer not having funds in hand to meet the demands as they arise; and your council are inclined to think that if the present state of the finance shall continue, it will be a wise course to call upon the members at no distant period to adopt some means for the liquidation of the debt."

Sir JOHN FORBES, who was received with loud cheers, moved that the report be adopted, and in doing so said, he thought they ought to pay the subscription of a guinea towards the objects of the Society itself, and an additional subscription of 10s., or whatever else might be deemed sufficient, towards the cost of the journal.

The report was unanimously adopted.

Sir CHARLES HASTINGS then consented to withdraw his resignation and continue President; he having been appointed President for life, three years ago, at Birmingham.

After votes of thanks to the auditors, to Dr. Alison, and to Dr. Williams, who was reappointed Secretary, the Medico-Ethical Committee was reappointed, with the addition of Dr. Styrup of Shrewsbury.

Dr. HENRY read the report of the Legislative Committee, which referred to the efficient performance of vaccination, the restricting of the sale of poisons, the warrants issued for regulating the rank and pay of Medical officers in the army and navy, and other subjects.

Mr. WATERS moved the adoption of the report, and the reappointment of the committee, with the addition of Richard Griffin, Esq., and Dr. Seaton, with an instruction to them to watch the working of the Medical Act, especially in regard to preliminary and professional education, poor-law Medical reform, public vaccination, and the sale of poisons.

Dr. MACKESY, of Waterford, proposed that the committee be also requested to consider the propriety of endeavouring to have the Medical Profession represented in the House of Commons.

The subject was added to the former resolution, which was then adopted.

Dr. DAVIES, of Bath, brought before the attention of the meeting the fact that the Edinburgh College of Physicians had granted their licence to a man who had been for years practising as a homœopathist in Bath, upon the recommendation of two men who were themselves homœopathists. He strongly condemned the laxity of the Edinburgh College in granting these licences without having made inquiries as to the character of the practice pursued by the applicant or the parties who recommended him. He proposed the following resolution:—"That in the opinion of this Association, the admission of homœopathists by the Edinburgh College of Physicians is highly reprehensible, and that the College was bound to make inquiries as to the character and standing of men not known to any of its members."

Dr. NOBLE of Manchester, seconded the resolution, and a very lengthened discussion took place upon it. It was finally carried by a large majority, five members only voting against it.

Dr. NOBLE then proposed:—"That in the opinion of this meeting, the conduct of the Edinburgh College of Physicians, in offering their licence for a money payment, to all applicants having any Medical or Surgical practice whatsoever, is reprehensible in the highest degree."

Dr. WILKINSON seconded the motion.

On the recommendation, however, of Sir CHARLES HASTINGS and Sir JOHN FORBES the motion was withdrawn.

On Thursday the business was preceded by a public breakfast at the Adelphi Hotel, after which there was a meeting of the members of the new Council.

The second general meeting of the members was held in the large theatre. Dr. Williams reported that the Council recommended the liquidation of the debt by a voluntary subscription of 5s. per member for two years. Dr. Joseph Seaton urged that his plan was preferable, as it was monstrous that the Association should be taxed to the amount of £300 a-year to save each member 4s. 4d.; and he moved as an amendment, which was seconded by Dr. Hughes, of Mold, that the postage of the *Journal* should not be paid by the

Association for one year. In the course of a discussion, Sir John Forbes advocated a moderate and yet permanent measure, urging that the payment of the postage by the members would place a surplus at the disposal of the Association, and enable it to do something more for medicine than merely giving the members the *Journal*. Dr. Bartrum, Bath, said that the change proposed in the amendment was a constitutional one, which could not be made without notice, which had not been given for this meeting, and 5s. a-year was such a serious thing to many of their members that the addition of it to the subscriptions would be objected to by 25 per cent. of the total number. On the law being read it was ruled that, although it entitled each member to receive the *Journal* for a guinea, it did not say he should receive it "free of postage." Several members urged that the debt arose from arrears for subscriptions, and others that it should be liquidated by a voluntary subscription, to which one member offered £10, expressing confidence that the £300 would be raised so soon as the subscription list was opened. The amendment was lost, and the meeting then divided upon the motion for a "voluntary" subscription, which was carried by 54 against 35.

It was resolved that the next meeting should be held at Torquay, and that Dr. Radclyffe Hall should be the President elect.

Dr. WATERS, of Chester, read an address on Fever, comprising a description of the various local manifestations of Typhus which had fallen under his notice in the course of many years' observation of the disease in this country and on the Continent. He argued that, as local phenomena in other diseases, such as gout, rheumatism, scorbutus, etc., were not held sufficient to constitute distinct maladies, so the local lesions in the affection known as dothi-enteritis, or typhoid fever, did not justify its separation, as a completely distinct disease, from typhus.

Dr. DAVIS proposed a vote of thanks to Dr. Waters for the very able and interesting address he had given them, and a request that he would allow it to be published.

Mr. GRIFFITHS, of Wrexham, seconded the motion, and it was adopted with acclamation.

After an adjournment for luncheon, and reassembling, Mr. CHURCHILL read the twenty-fourth annual report of the Benevolent Fund Committee. The progress of the fund during the year had been satisfactory. The ordinary subscriptions had exceeded the amount received in the previous (a festival) year, while in the form of an extraordinary donation a legacy of £3000 had been left to the fund. The committee had afforded assistance to a larger number of cases than during any previous year, the sum of £1067 having been distributed to 92 applicants for temporary aid, while £255 was given to 16 annuitants. The success of the fund was not dependent upon constant measures to keep it before the public, but manifestly upon the good feeling and sympathy earned by the constant endeavours to accomplish as large an amount of benefit with as little expense, trouble, and publicity, as practicable. This principle the committee trust will make assistance more readily accessible to the unobtrusive poor who have not heart or means to make their sorrows known—a principle the success of which would render charity more worthy of its name. The legacy of £3000 was left by a Medical man—the late Mr. Hime; and the fund was brought under his notice and recommended to him by another Medical man—Mr. Walker, of Budleigh Salterton.

The balance sheet showed that there were balances of £72 and £155 in favour respectively of the donation and the annuity funds.

Mr. CHURCHILL added that the good done was limited simply by the funds in hand, and if each member of the Association would but subscribe 5s., the income of the Benevolent Fund would be increased by £500.

Sir JOHN FORBES said that this fund and the Epsom College were complements to and not opponents of each other.

Mr. NEWNHAM said there were 15,000 Medical men, of whom 1005, in fifteen counties, were subscribers to the British Medical Association, 174 only of these being subscribers to the fund. In Lancashire there were 257 members and 30 subscribers to the Benevolent Fund; in Cheshire, 47 and 7; and in Yorkshire, 157 and 14.

The report was adopted, and the reading of papers was then proceeded with. Dr. Hibbert Taylor, of Liverpool, read one upon "A Peculiar Form of Scleroticitis."—Dr. Birch, of London, advocated oxygen as a therapeutic agent, describ-

ing its curative properties in many diseases, and mentioning, among many otherwise intractable cases, that of a lady in London suffering from heart disease, who had been kept alive for three years by periodical doses of the gas; and another of a Physician whose vision had been restored by it.—Mr. W. Morris, Gildersome, next spoke on the treatment of tonsillitis.—Dr. Nevins, of Liverpool, described the operation of the internal administration of medicines in the form of vapour, by such methods as the smoking of mercurial cigarettes, or the simple burning of touch-paper. He had applied this mode of treatment in cases of bronchitis. Dr. EVANSON had also used this mode of treatment effectually, applying turmeric in cases of catarrh; and he produced some toothpick-shaped camphor quills or cigarettes, which were simply held in the mouth, which had been found good substitutes for respirators, and were declared by many members of Parliament to be an excellent antidote to the vapour of the Thames.—Dr. Mitchell, of Liverpool, read a paper on a case of neuroma.—Dr. EVANSON volunteered a notice of a disease, cynanche sub-maxillaris, to which children were subject, and which had not been recognised as a distinct malady. It was the twin sister of mumps, but was the swelling of the sub-maxillary glands, more troublesome than serious. Saline aperients, followed by tonics internally, with emollient applications to the tumours, had been found the best mode of treatment; but an early incision was recommended when matter had distinctly formed.

Mr. GRIFFITH, of Wrexham, made some remarks on the use of the saturated tincture of ergot in cases of hæmorrhage in obstetric practice, and commended it as an indispensable and invaluable companion to the Medical man engaged in such practice. He also spoke of the great value of turpentine in stopping hæmorrhage in cases where the powers of life were rapidly passing away.

Mr. PROPERT, of London; Mr. PARKER, of Kirkdale; Dr. EVANSON, and Mr. MORRIS spoke on the same subject. Mr. PARKER said, as well as turpentine, the injection of cold water was attended with the best and happiest effects.

On Friday morning, about 100 members breakfasted with the Mayor, at the Town Hall. The Mayor was supported by Sir John Forbes and Sir C. Hastings. His Worship proposed "Prosperity to the British Medical Association and the health of Dr. Vose." The President acknowledged the toast, and proposed the health of the Mayor, stating the anxiety he had evinced to offer his hospitality to the members of the Association. The Mayor, in acknowledging the toast, expressed the great pleasure he felt in receiving the members, and assured them of the interest he took in the welfare of the society. He then proposed the health of his guests, and coupled with the toast the name of Sir C. Hastings, who in responding, expressed, on behalf of the Association and himself, most cordial thanks for the great kindness, courtesy, and elegant entertainment which his Worship had provided.

At eleven in the forenoon the last general meeting took place at the Medical Institution, Dr. Vose presiding.

A letter was read from Dr. Bell, of Goole, in reference to a resolution as to stamp duties on diplomas, which Sir Charles Hastings said had been rendered unnecessary, because an intimation had been received from the Home Office that the Government intended to remit the stamp duty on Medical licences.

The PRESIDENT next introduced Mr. A. T. H. Waters, to whom, he said, they were especially indebted for any success which had attended the local arrangements and the reception of the members in Liverpool.

Mr. A. T. H. WATERS then delivered the address in physiology, which was a very able *resumé* of recent advances in that science, especially in the knowledge of the nervous system.

Dr. RADCLYFFE HALL moved a vote of thanks to Mr. Waters.

Dr. MARKHAM, of London, seconded the motion, which was carried by acclamation.

The reading of cases was then resumed.

Dr. SKINNER, of Liverpool, read a paper on the retroversion of the gravid uterus.

Dr. CAMPS submitted to the attention of the meeting a case of cerebral or subjective vision, from which a gentleman of 60 years suffered. He was haunted by an ocular phantom in the shape of a woman dressed in grey, whom, although perfectly aware of the illusory nature of the appearance, he

saw with as much distinctness as an actual presence in his bedroom every night. Aperients, change of scene, and other treatment of a similar kind removed the hallucination, but the patient subsequently became affected in the brain. This instance Dr. Camps submitted as one not of an affection of the retina, but of a cerebral or subjective nature.

Dr. ROUTH proposed a vote of thanks to the readers of papers and cases, which was seconded by Mr. COLEMAN, and carried by acclamation.

Mr. PROBERT proposed that the cordial thanks of the meeting be given to the Council of the Liverpool Medical Association for the arrangements made for the reception of the members.

Mr. MORRIS seconded the motion, which was likewise carried by acclamation.

Dr. EVANSON moved a vote of thanks to Dr. Vose for the very able manner in which he had presided at the meetings of the Association.

Mr. NEWNHAM seconded the motion, which was carried unanimously amid loud applause.

This closed the session.

After partaking of luncheon, the members enjoyed a trip up and down the river in the *Jackal*. In the evening they dined together at the Adelphi Hotel, and the meeting closed.

ASYLUMS AND HOSPITALS FOR THE INSANE.

THE annual meeting of the Association of Medical Officers of Asylums and Hospitals for the Insane was held at the Liverpool Medical Institute on Tuesday. Sir Charles Hastings, D.C.L., presided, and expressed his belief that this association would furnish valuable knowledge in regard to insanity, and remove the diversity of opinion amongst Medical men on this subject. At present the lunacy laws were in a very imperfect state, and their present interpretation by the judges was altogether at variance with that of Medical men, who had devoted all their lives to the observation of cases of insanity. The present lunacy laws were very injurious to the insane, and they constantly impeded the operations of Medical men. A prejudice also existed against the confinement of the insane, and they were too ready to attribute sordid motives to those who advocated the adoption of this course. He had never known any injury to result from the present system, which enforced examination by two Medical men before confinement. The newspapers were every day informing the public of crimes and offences perpetrated by lunatics who ought to have been under control. With reference to Mr. Walpole's Lunacy Bill, the President commented strongly upon the fact that the evidence of those who had given their time, their talents, and, in some instances, their fortunes, to the care of the insane, had not been taken when the Bill was in committee. He also objected to several clauses of the Bill, but particularly to that which authorised secret reports. There were several facts connected with pathological psychology which demanded the serious investigation of the Association. The most important was intemperance, which was said to be the cause of 70 per cent. of the cases of insanity. His opinion, however, was that intemperance was not a cause, but a concomitant of insanity. Tobacco, which was now in almost universal use, was also a most important subject for investigation, with regard to its bearing upon the question of lunacy. It was in its action upon the system debilitating in the extreme; it caused an unnatural action of the heart, and great depression of spirits. These effects showed the necessity of considering and discussing the tobacco question in its bearings upon lunacy.—Dr. Bucknill, of Exeter, was appointed President for the ensuing year. Resolutions were passed to secure more reliable lunacy statistics, and a reform of the lunacy laws.

NEW LIGHTS.—The Registrar of Maldon, in Essex, requests information in respect to registering deaths that arise from neglect of procuring Medical advice. A sect called "New Lights," one of whose tenets is to abjure all Medical skill, are constantly losing children in this district.

REVIEWS.

Lectures on Pathological Anatomy, delivered at Guy's Hospital during the Summer Sessions of 1857, 1858. By SAMUEL WILKS, M.D. Lond., F.R.C.P., Assistant Physician to Guy's Hospital, Lecturer on Pathology, etc., etc. 8vo., pp. 472.

Dr. WILKS has undertaken a task which we will venture to say that few men in this country are capable of performing as well as he. The reason of this is, that pathology, as a necessary portion of Medical study, has never received from our Medical Examining Boards the recognition which it deserves; and it is evident that, unless men are incited by some good and substantial reason to devote themselves to this branch of instruction, we cannot expect to meet in every School of Medicine with a pathologist so thoroughly acquainted with his subject as Dr. Wilks is known to be.

Dr. Wilks very truly remarks:—"It would be well if the several Licensing Boards insisted on the more systematic treatment of pathology by those in our Hospitals who are qualified to undertake the task. Such teachers would then occupy a position in England analogous to that which in the Continental Universities is filled by some of their most distinguished Professors."

Dr. Wilks has (as he informs us) for the last fifteen years made a daily study of the dissection of the dead; and has the splendid museum of Guy's Hospital as the scene of his operations. The amount of his opportunities may be gathered from the fact stated by him, "that he has carefully abstained from making any statement unverified by his own observation and experience."

It is of course impossible for us to enter into an analysis of the contents of the volume thus brought to light. We can only pretend to speak of it as a performance, and as a whole. Does it fulfil the objects for which it was purposed; and was it needed for the purposes of the Profession? To both these questions we answer emphatically, Yes. A book of this kind, done in this form and fashion, was most needed in our language. It is true that we have plenty of works on pathology; but a summary of facts—of facts as we know them at this day—we do not possess. We should compare the volume to Hasse's. What Hasse's was when it was published, this is now. And one especial excellence we should notice in connexion with it: the author is not a mere pathological anatomist; he is a Physician. He leaves the imprint of this fact on every page of his work. He does not merely describe the diseased process, but he argues of it as a man whose business it is to treat diseases. We need not, therefore, say that the last term to apply to this book would be that of compilation. We find at every page disputed points of pathology well discussed; both sides of the question fairly stated, and then a cautious expression of opinion on the part of the author. He is not a man who passionately takes up one side of a question, and can see no light except by the aid of his own taper.

But he does more than this: his large experience enables him to offer many new suggestions, and to point out some new facts in reference to pathology; and to clear up some of the disputed questions affecting it. We will give a few specimens of Dr. Wilks' way of doing these things. Speaking of hypertrophy of the heart, he says:—

"There are some who think that the fibres (muscular) actually grow in size, but of this there is some doubt, although there can be none as to their increase in number. I have constantly seen fibres sending out offshoots, or splitting in two; and, also, I have seen nucleated fibres which probably were the germs of new tissues."

Dr. Wilks also points out the fact, that in hypertrophy of the right side of the heart the walls of the right side are not only thicker but also tougher than natural. He does not, however, explain the reason why this "leathery consistence" of structure should exist on the right and not on the left side.

He points out another important fact, viz. that in rheumatic inflammations of the heart—e. g. in fatal pericarditis,—the fibrillæ of the adjoining muscular tissue will be found granular. It is by this alteration in the muscular structure that he explains the sudden deaths which sometimes occur in acute rheumatism.

A good specimen of Dr. Wilks' way of handling his

subject will be found under the head of "Inflammation of the Pericardium." This difficult subject is well treated. We notice that Dr. Wilks, like Kölliker and certain other observers, doubts the fact of bloodvessels extending into the endocardium, and the fact of the mitral valves having been actually injected. We recommend this point to the consideration of Dr. Richardson, who speaks of the hyperæmic condition of the valves induced in those parts.

We would gladly give some further examples of our Author's style, but we really feel a difficulty in selecting one in particular. We can only add, that we believe Dr. Wilks has really bestowed a very great boon on the student and the Profession by the publication of this volume. He tells us that the matter stands as it was delivered in his lectures, and hereon we must say one word. It is this,—that in a future edition Dr. Wilks should remove all appearances of the colloquial style from his pages. We take it that every writer ought to write carefully when he faces the public in print. Let us give two specimens of the kind of writing we object to. "I have already shown you how remarkably the hypertrophy of the right ventricle differs from the left" (p. 75). Again, at p. 74: "In some of these the orifices are increased." Dr. Wilks evidently means *enlarged*. We need not point out the defect in the former sentence.

These blemishes are evidently the consequence of the lectures being published "in the exact form in which they were originally delivered," and will doubtless disappear in the next edition of this most useful and valuable work.

An Inquiry into the Curability of Consumption. By JAMES TURNBULL, M.D., Physician to the Liverpool Royal Infirmary. Pp. 195. Third Edition. London: 1859.

THE fact that this book has reached a third edition is a sufficient evidence of the interest taken in the subject to which it relates. Dr. Turnbull informs us that the present publication, in addition to being revised and in many parts re-written, has been so much enlarged that it may almost be regarded as a new work. Those who have not read it may be informed that, without possessing any very striking claims to novelty, either as to the pathology or treatment of consumption, it contains much interesting matter in reference to this very serious malady, and that the views inculcated are generally sound and judicious.

A Memoir on the Treatment of the Epidemic Cholera, read before the Members of the French Academy of Sciences, with their Report thereon. By JOSEPH AYRE, M.D. Pp. 44. London: 1859.

THIS memoir was presented to the French Academy of Sciences, in answer to a circular issued in 1854 by that body, which announced that a French gentleman had bequeathed a large sum of money to be given as a prize to the discoverer of a remedy for Asiatic cholera in its stage of collapse. It was required that the remedy proposed should have saved an immense number of cases, and should be entitled to rank as of equal value with quinine in the treatment of intermittent fever. Dr. Ayre's remedy, as is well known, consists of calomel given in small doses and very frequently repeated, and this Physician believes that the drug in his hands, and in those of others, has really fulfilled the ends required. After the lapse of four years, the report of the Commissioners was given in, and was printed in 1858. It is stated that 153 memoirs were sent in; but, in the opinion of the reporters, only two of the authors appeared to understand the real object of the *concours*. One of these memoirs was by a Russian Physician, and the other was by Dr. Ayre. The reporters, however, while admitting the value of Dr. Ayre's observations, think that the cases are not sufficiently satisfactory to carry conviction into their minds, as to the preponderating efficacy of the calomel treatment over other kinds of medication. Dr. Ayre publishes the memoir, together with the testimony afforded by numerous Practitioners as to the value of his treatment, which he believes to be the best ever proposed. Much credit is due to Dr. Ayre for the labour he has bestowed upon the subject of cholera since the first introduction of the disease into this country, and although we share the scepticism of the French Commission, we willingly listen to the experience of a Physician writing in his seventy-eighth year, and after twenty-five years' acquaintance with a very destructive epidemic.

PROGRESS OF MEDICAL SCIENCE.

Selections from Foreign Journals.

ON UNUNITED FRACTURE.

By Dr. MARKOE.

IN a clinical lecture, Dr. Markoe takes an interesting review of this subject. He observes that the public unjustly holds the failure of union after fracture to be presumptive evidence of the incapacity or inattention of the Surgeon in charge; but, after all that science, skill, and care can do, there will still remain a certain number of cases in which union fails wholly or in part—1 in 600 or 700 cases of fracture being probably near the proportion. The subject may be considered in relation to the pathological condition of the parts, the symptoms and effects, the causes of the failure of union, and the treatment that should be adopted.

Pathological Conditions of Ununited Fractures.—Excluding from our notice the cases of mere delayed union, for which time and patience are alone requisite, we may find one of the following conditions present: 1. *The entire absence of union.*—It is very rare to find no attempt at union whatever. Still, sometimes either the system is so borne down by some wasting and rapidly exhausting disease, or the local conditions are so incompatible with union, that the reparative nîsus is in no degree excited, and the fragments indicate no appearance of commencing bony exudation. Such a condition is sometimes seen after severe and finally fatal injury, when the constitutional powers never completely rally from the depressing effects of the injury or its immediate consequences. 2. *Ligamentous union* is the term applied when the uniting medium remains soft and flexible instead of becoming ossified. This is by far the most common condition in which ununited fracture is found on inspection. It is usually due to constitutional causes, the reparative powers seeming sufficient to produce enough of the uniting medium, but not to effect its elaboration into bone. 3. *Union by fibrous bands.* This class of cases is closely allied with the last, the uniting medium, however, being distributed around the fractured ends in mere bands of well-organised fibrous tissue passing from one fragment to another, and binding them but loosely together. Or the bands may rather resemble areolar than firm fibrous tissue—a circumstance not infrequently observed in ununited fracture of the cervix of the femur. When the fibrous bands are considerable in number and strength, short, and entirely surrounding the ends of the fragments, they may form a tolerably firm bond of union; and, if we suppose the ends of the bone enlarged by ossific deposit, and their opposed surfaces mutually adapted to each other, we then approximate to—4. *The false articulation.* When the bony surfaces of this play upon each other they sometimes become covered with a layer of condensed fibrous tissue, representing articular cartilage, and which in some rare instances becomes covered by a complete synovial membrane. Partial formations of such synovial membranes may be seen in every museum.

Symptoms.—There is no difficulty in the diagnosis of these cases, but a careful study of the appearances presented in each case throws much light on the nature of the case, and probably on the causes which may have led to the failure of the union. 1. *Pain and inconvenience on motion* usually characterise only the early stages, before the soft parts have become accustomed to the displaced condition of the fragments and before the passing away of inflammatory action. At a later period there is absence of pain on motion. 2. *Deformity* is invariably present, being generally characterised by shortening. Sometimes it is not observable as long as the limb is at rest; but on the patient making the slightest motion, the action of the muscles brings out an angularity, or a prominence of one fragment, or a shortening, which then becomes a marked feature of the case. 3. *Mobility* is a constant and characteristic sign of the affection, varying from a mere yielding at the fractured point to the most helpless, dangling condition. It increases with the use of the part. 4. *Uselessness of the limb* is, as a general rule, a consequence of this mobility. This is especially the case with regard to the lower extremities, on account of the sustaining power they have to exert; and mechanical appliances which are of

such service in ununited fracture of the upper extremities, are with respect to them, of little avail. The author refers to the case of a sailor with fracture of the humerus, who could perform the most arduous duties, and such instances are not uncommon. One important consequence of this uselessness is the production of *atrophy*, the muscles wasting, and the bones becoming light and porous. This tendency suggests the important precept not to delay operative interference too long.

Causes of Failure.—These may be referred to *diminished, diverted, and obstructed power*, the two first being constitutional, and the latter local in their nature. 1. *Constitutional causes dependent upon diminished power.* (a.) *Old age* is sometimes a cause of non-union; but usually at any period short of the most advanced senility we may expect bony union. (b.) *Disease of a general and constitutional character* may in certain cases, as in scurvy, low fever, cholera, and other exhausting diseases, prevent or retard union. (c.) *Debility* when extreme, may act in the same way; and the author refers to a case in which starvation at sea prevented union during nine weeks, the fracture rapidly consolidating under the influence of nutriment. (d.) *Paralysis* prevents union in certain cases by impeding nutrition; and the author refers to a case in which fracture only consolidated as recovery from a paraplegia began to take place. 2. *Constitutional causes from diverted power.* (a.) *Pregnancy and lactation.* The author refers to a case of fractured arm which refusing to unite during pregnancy, consolidated very well after the birth of the child. (b.) *Other extensive injuries*, whether in the vicinity of the fracture, or at a distance from it, seem sometimes to divert the energies of repair from the fracture, so as to lead to a failure of union. This cause of non-union is not infrequently met with at the New York Hospital, where many cases of severe injuries are treated. 3. *Local causes acting by obstruction.* (a.) *Want of proper apposition.* This is always an unfortunate circumstance, both as regards the strength and the promptness of the union, and in some aggravated cases may entirely prevent it. But that by itself, even when existing in a very great degree, this is not always an impediment to union, is shown by daily experience. "And here I should call your attention to the fact, that none of the causes of non-union, either local or constitutional, must be expected, in all cases, to produce an unfortunate result. The truth is that these causes should be regarded as tending to the obstruction of firm bony union, and as interfering more or less with the completion of the various processes through which this union is elaborated, but not as capable, in any large proportion of cases of preventing it. Failure of union, therefore, even where these causes of failure exist in a very marked degree, is rare and exceptional. The reparative powers are so great and so intelligent in their action, that they are able to triumph over the larger proportion of the obstacles which may be placed in their way." (b.) *Too much motion of the limb during treatment*, when existing in conjunction with want of due apposition, is not an uncommon cause of non-union; but at the same time it is surprising to observe how great a degree of motion, during all the time of treatment is compatible with firm, and often undeformed union. (c.) *Tight bandaging* is mentioned by many writers as a cause, but it can only become so by the most reckless disregard of ordinary surgical precautions. (d.) *Excessive inflammation at the seat of fracture.* This may delay the commencement of repair, and there is danger of its going on to suppuration. Even where it does not reach so high a point as this, the postponement of the reparative action seems so to thwart nature's intentions, as sometimes to put her altogether aside from her original purpose of repair. (e.) *Rupture of the nutrient artery* is affirmed by M. Guérétin to be a cause of non-union; but his views are not confirmed by the investigations of Dr. Norris, of Philadelphia. (f.) *The interposition of tissues* between the broken fragments, is, in the author's experience, not an uncommon cause of non-union; but its influence is doubted by Norris. (g.) *Fragments of bone and foreign bodies* lying between the fractured ends, will often prevent or obstruct union by exciting and keeping up excessive suppuration. This is often a cause of delayed or imperfect union than of non-union, as nature seems to provide against the difficulty by throwing out a superabundance of reparative matter which encloses the broken ends, foreign body and all, in one strong casing, which finally becomes a firm bond of union,

and particularly so, if after a time, the foreign body, as is often the case, is got rid of.

Treatment.—A large number of cases in which, after six or eight weeks, no union has occurred, are merely examples of delayed union, requiring only additional time for its accomplishment; and any case in which some local impediment cannot be clearly discovered should have such additional time granted it. But when this is not of avail, one of the following means may be had recourse to:—(1.) *Friction of the broken ends on each other.* This was one of the earliest and simplest procedures; and repeated until considerable action is excited, and then combined with moderately firm pressure by means of splints and the allowance of a longer time, will be of avail in certain cases in which the local impediments to union are not serious, the reparative powers merely wanting to be roused into action. (2.) *Blisters, or other Counter-irritants*, applied to the integuments in the immediate neighbourhood, sometimes may stimulate sluggish action. Of this means, however, the author has had no experience. (3.) *Electricity* has been extensively used in the New York Hospital, and occasionally with acupuncture. Some efficacy has in general been attributed to it in cases where union was long delayed; but it has not been employed with success in an old case. (4.) *Salivation.* Some successful cases have been reported by reliable observers; but Dr. Markoe can say nothing of the treatment from personal observation. These four methods embrace what may be termed the *Medical* treatment of ununited fracture, the intention being to excite reparative action by remedies not directly applied to the faulty part. The following embrace the more strictly *Surgical* methods of treatment, deriving their efficacy from changes effected in the condition of the ends of the bones:—(5.) *Drilling* the broken extremities so as to reproduce, to a certain degree, the conditions of a recent fracture, was introduced by Brainard, of Chicago. It may be repeated every eight or ten days, according to the effect produced, the parts being maintained in good apposition and at rest. "We have employed it in a number of cases in this Hospital, and in some of them with very satisfactory success. It has the great merit of being comparatively safe, and, in a certain class of cases, not the worst, it is a very valuable Surgical resource." (6.) *Seton.* This treatment originated with Dr. Physick, of Philadelphia, though probably first suggested by Winslow in 1787. Dr. Physick left the seton in for several months, or until union had become firm. Others have removed it before it had done more than excite common inflammation. Some have passed the seton near, instead of between, the bones; while wire has been the material employed in certain cases. "This plan of treatment has now been in use so long and so extensively as to be fully established as a valuable and, in appropriate cases, a successful operation; but it is a striking instance of national prejudice, that scarcely one of the great names of England, France, or Germany, is willing to accord to it anything more than an equivocal position, as a remedial resource, in ununited fracture." (7.) *Resection.* The bones thus freshened are either kept in place by splints and bandages, or they are fastened together by silver wire, which secures their more accurate contact. "This is a most powerful means of exciting action in obstinate cases, but it has the serious disadvantage of severity and danger. The injury is necessarily converted from a simple into a compound fracture; and this circumstance alone, particularly in the larger bones, is sufficient to account for the fact that the operation is not infrequently fatal. It is, therefore, only to be regarded as the last resource in Surgery, and not, even as such, to be lightly resorted to." (8.) *Amputation.* Although this cannot be regarded as a means of cure, it must be mentioned as one of the things which is sometimes required to be done. "It can only be properly regarded as a means of ridding the patient of what cannot be cured, and in no case more strongly felt to be the *opprobrium chirurgorum*."

The author refers to, as valuable sources of information, Dr. Norris's paper in the *American Journal of Medical Science*, vol. xxix. (1842), and to the article "Fracture," in the *Cyclopedia of Practical Surgery*.—*New York Journal of Medicine*, May, pp. 371—385.

THE *soirée* at the College of Physicians on Wednesday passed off with unusual animation. Most of the members of the General Council were present.

FOREIGN CORRESPONDENCE.

FRANCE.

PARIS, August 1, 1859.

THE application of electricity to the treatment and cure of disease may now fairly be considered as an essential complement of a complete curriculum of Medical study. Discovered some two centuries ago, electricity continued for many years in the hands of natural philosophers and magicians; and it is only within the last century that it has found its way into the domain of practical medicine. Jalabert, a physician of Geneva, has the credit of having been the first to avail himself of it as a therapeutical agent, and his example was followed by Lindulph, a Swedish Physician, and also by the famous Haen. Their experiments, however, were so very imperfectly conducted, and the practical results following them so very unimportant, that this powerful agent was for a time abandoned. Its importance, however, became revived, and an impulse was given to its study, by Poma and Arnaud, of Nancy, who published in 1789, an able treatise on the subject, in which they relate numerous cases of important diseases, such as rheumatism, scrofula, paralysis, etc., in which its application was attended with a certain amount of success. Soon after the publication of this treatise the practical value of electricity became pretty generally known; but, as is often observed in the history of new discoveries, and more especially in reference to medicinal agents introduced for the first time, the inductive process of reasoning is frequently departed from, absurd and ridiculous theories are built up, and the discovery, in which there may be much inherent virtue, becomes an object of ridicule, and is often altogether discarded. This may be said to have been the case with electricity.

Contemporaneous with these writers, two famous individuals, Galvani and Volta, discovered a new source of electricity; but either from ignorance of its peculiar properties, or in consequence of the imperfection and inapplicability of their apparatus, they were unable to develop and demonstrate, in a practical point of view as regards physiology and therapeutics, the merits which future experimentalists found it to possess. A step in advance was made by Sarlandière, who, by his system of "electro-puncture," was enabled to pass the electric fluid into the deep-seated tissues; but this method is attended with so much pain, and is occasionally followed by accidents of such a troublesome kind, that it has been abandoned in Medical practice, and is now but occasionally employed in certain affections of a purely surgical character. Nevertheless, this method of Sarlandière, which was warmly advocated by Majendie, and other eminent physiologists of the day, was a decided improvement on the more ancient modes of procedure, and gave, as it were, new life to Medical electricity. A few years ago a new sort of electricity was discovered by Professor Faraday, to which he has given the name of "electricity by induction," and which has been found to possess properties peculiar to itself, serving to distinguish it from that derived from all other sources. The currents proceeding from this new source are known to produce, when introduced into the system, peculiar physiological phenomena, which have led to its employment in the treatment of a numerous class of diseases to the entire exclusion, except in one or two Surgical affections, of the static electricity. A celebrated French Physician, M. Duchenne, of Boulogne, has availed himself of the discovery of our distinguished countryman, and to him we are indebted for a full exposition of its value and its adaptation to the treatment of a great variety of diseases intractable in their character, and sometimes setting at defiance every other method of cure. By an ingeniously-devised apparatus, and by the adaptation to this apparatus of a variety of exciters, M. Duchenne has been enabled to direct the electric currents to each particular organ of the body, and to limit their power at pleasure. By this new method, to which he has given the name of "local electrification," he can act either on the surface of the skin, or its deeper-seated layers; or he can act on the muscles and internal organs, without interfering with the super-jacent tissues. The great advantage of this system over the more ancient method, is at once recognisable, when we consider, that by the latter it was necessary, in order to act on the muscles or

internal organs, to puncture and incise the skin, thus interfering with its integrity, exposing it in some instances to disorganisation while the entire nervous system was rendered liable to preternatural stimulation. In the Hospitals here, we observe, that besides the apparatus of M. Duchenne, another, the production of Légendre and Morin, is also employed in Faradisation. The principle on which both are constructed is the same, although a preference is given to the latter by Briquet, and other Physicians, owing, we believe, to its greater simplicity. In this apparatus the primary motor power is a galvanic current proceeding from a Bunsen pile, which by its influence electrifies small bars of soft iron, and so renders them magnetic. The iron having become a magnet, acts in its turn by influence on a very fine wire placed near it, and there determines the electric current called "current by induction."

Local electrification, or Faradisation, M. Duchenne treats of under three great heads:—1. Electrification of the skin; 2. That of the muscles; 3. That of internal organs, the organs of sense together with the organs of sensation. We shall as briefly as possible notice these three divisions in succession, and our remarks will be a simple condensation of the views of this celebrated Physician, as exposed in his treatise, published some three years ago, and entitled, "*De l'Electrification localisée et de son application à la Physiologie, à la Pathologie, et à la Thérapeutique.*" Regarding the subject as one of intense interest to the Profession, and considering it just possible that the above treatise may not be familiar to all your readers, we deem it advisable to lay before them such parts of it as may interest them most, and which may tend to stimulate them in the further prosecution of this important branch of Medical therapeutics. Different parts of the skin being endowed with different degrees of sensibility to the electric currents, it naturally follows that in Faradising different regions some modification in the method or manner of performing it becomes necessary. For this reason Duchenne divides the different methods of cutaneous Faradisation into three classes:—1. Faradisation by the electric hand. 2. By metallic exciters, that is to say, by the application to the pole of globular, oval, or conical pieces of metal. 3. Faradisation by means of metallic cords. The peculiar effects to which each of these methods gives rise are different in each case, and hence their application requires a special study.

Faradisation by the Electric Hand is accomplished in the following manner:—A wet sponge, enclosed in a cylinder, is attached to one of the poles of the machine; the sponge is then applied to a portion of the skin endowed with but a small degree of sensibility, as, for example, over the sacro-lumbar region; the second exciter connected with the apparatus is held by the operator, who, after having carefully dried the skin by means of some absorbent powder, passes his hand rapidly over those parts which he wishes to stimulate. This is the mildest form of cutaneous Faradisation, and, except when applied to certain parts of the body where the sensibility is exceedingly great, its effects are barely perceptible.

Cutaneous Faradisation by solid Metallic Bodies is effected thus:—The skin is carefully dried, as recommended for the electric hand, unless in those cases where the epidermis is thick and hard, as happens sometimes in those persons whose calling exposes them to much contact with the air, or substances calculated to harden it; in these latter cases it is even necessary to moisten the surface, in order that the electric excitation may penetrate the entire derma. This done, the metallic exciters, whether oval, conical, or globular, are passed over the skin. The globular, and the oval, or olive-shaped, are intended to excite by their convex surface the skin of the limbs and the thorax, while the conical-shaped exciters are used in the Faradisation of the scalp. All these solid metallic exciters must be passed with more or less rapidity over the affected parts; cases do occur, however, where it is necessary to produce a very powerful revulsion in a limited space, and to accomplish this the point of the olive-shaped exciter must be left in full contact with such spot until the desired effect be produced. From the extreme pain to which the contact of the olive-pointed exciter with the skin gives rise, it has been designated the "clou électrique" (electric nail), the patients comparing the sensation to that which might be produced by a burning nail driven into the skin. This form of Faradisation can be applied especially in the neighbourhood of the vertebral column.

Faradisation by Metallic Cords.—The metallic cords are used in the form of small rods, or small brushes, which are fixed in cylinders, the latter of which are attached to the isolating handles by means of screws. Sometimes the Faradisation is accomplished by whipping the skin with the metallic brush, and sometimes the brush is allowed to remain in contact with the skin as long as the patient can bear it. The former method is that most frequently in use; the latter can be with difficulty supported by the patient, and is had recourse to only in deep-seated affections, such as white-swelling of the knee, or other important articulations. This is called the "electric moxa."

The limits of a single letter do not permit of our proceeding farther with this extensive and interesting subject. We shall therefore in a future communication resume it, and take occasion to notice the physiological effects of Faradisation in all its different forms and bearings, together with its therapeutical action in reference to some of the more important diseases in the treatment of which it has latterly been extensively employed.

GENERAL CORRESPONDENCE.

THE EDINBURGH COLLEGE OF PHYSICIANS.

LETTER FROM DR. HALDANE.

[To the Editor of the Medical Times and Gazette.]

SIR,—The attention of the Council of the Royal College of Physicians of Edinburgh has been directed to a statement by Dr. Laycock, a Fellow of the College, in the *Medical Times and Gazette* of the 23rd inst., to the effect that "so few of the applicants (for the Licence of the College) were found ineligible by the Council of the College, that for all practical purposes the number of applicants for the Licence may be considered nearly equal to the number of recipients."

To this statement, which is founded upon the most palpable ignorance of the proceedings of the Council, I am instructed to give an unqualified official contradiction.

On the impropriety of such an unfounded assertion, under the circumstances, the Council cannot believe that there will be any difference of opinion.

I am, &c.

D. R. HALDANE, Hon. Sec.

Royal College of Physicians, Edinburgh,
July 30, 1859.

A FRESH ALARM FROM THE COLLEGES.

[To the Editor of the Medical Times and Gazette.]

SIR,—I feel very grateful for the sympathy which you have expressed for me, for I hope it is an earnest of the justice I ask from the Medical Council. I am grateful, too, that your exertions have been so effectual in bringing the Royal College of Physicians of London to a more legal course. But you mistake the terms of my letter in drawing the conclusion that the College pursued the course of conduct I described, during only twelve or eighteen months. The first announcement of its determination to grant the title of Doctor, was made in 1838; in this present month of July, Dr. F. Hawkins, the late Registrar, was addressing Licentiates by that title, and although the College may have resolved to withdraw their long-standing declaration, it is not yet done. So that twenty-one years of prescriptive use of the title of Doctor by Licentiates have elapsed. I am very curious to see the terms of the public withdrawal, for it is very certain, that as a simple act of justice, it should express the intention of the College to repair the loss and injury of those who have suffered from its former unwarrantable proceedings. Perhaps a full pecuniary compensation would be the most tangible expression of sympathy and repentance; or it might be recovered in a court of law.

But, Sir, I am in a fresh alarm. It appears that the Colleges have resolved to have three classes of Physicians,—namely, Fellows, Members, and Licentiates,—and that the Licentiates are to be the General Practitioners. I have the highest esteem for the whole body of General Practitioners, but I complied with an Act of Parliament, and took the licence of the College for the express purpose (and with

the express understanding with the College to that effect) that I should, and would, cease to be a General Practitioner. If, then, this new order of "members" be established, I shall be remitted to the general body, and all my cost and trouble of preparing for, and passing the College examination, be rendered useless. Where, I ask, is the justice of this? You may reply, that the College will admit Licentiates to be Members without examination; but let me ask whether they will do that without demanding a money-payment? I have the gravest doubts on that score, for on no occasion that I know of did a College confer titles of the kind wholesale, without a *quid pro quo* in hard cash.

But even were the College to grant the title of "Member" to existing "Licentiates" free of all expense, has it a legal right to do so? or would the title be legal? I have read the charter over and over, and I can find no mention of any "Members" of the College, except Fellows. A Fellow, therefore, (if I change my title) and a Fellow only, I must be. As a Physician by law, I hold myself to be legally the *socius* of the most accomplished of the present Fellows; and as a member of the Medical Profession, I hold myself to be the equal in Professional knowledge to the majority of them.

One word in conclusion: I tremble for the honour and dignity of the Profession when I see its Colleges, one after the other, seeking to replenish their treasuries by the sale of honorary titles that *can* be used by the purchasers in no other way than as shams and puffs. First, the London College of Surgeons made hundreds of "honorary" fellows at £10 or £20 a-head. Then the Edinburgh College of Surgeons caught up the profitable idea; but happily with less success. Next came the Edinburgh College of Physicians, with its licences at £10 a-head (exclusive of £15 stamp-duty), and the London College with its more costly licences (£41 17s. each), and preparatory to a distribution of honorary fellowships at £55 each, stamp included. Now it threatens to compete with membership and license at a lower figure with the Edinburgh College; while the Dublin College comes into the market too; but suspecting that the unblushing venality of its frail sister colleges will damage their reputation, demands *half* an examination! Just as a "Social Evil" in a spicy bonnet might say to two other "Social Evils" in showy Di-Vernon hat and feathers, "O fie! baggage!"

Was the Profession ever so degraded? I am an oldish man, and a reading "salt," but I do not remember anything at all like it. On the contrary, I remember in my younger days, vigorous reformers bawling through their rough but honest throats, "One faculty!"—and we have come to this!

I am, &c.

AN "EXTRA-LICENTIATE" AND M.D. OF ERLANGEN.
July 23rd, 1859.

P.S. Let me put this question in another form: suppose the Royal Society admitted persons as the Colleges are admitting, how long would it remain "respectable?"

POISONING BY PAREGORIC.

[To the Editor of the Medical Times and Gazette.]

SIR,—If you think the following case of poisoning in a child five weeks old would interest any of your readers, I beg to request a place for it in your next number.

The child of Gunner M'Gowan, Royal Artillery, was brought to me by his mother at 4 p.m. on the 28th ult. and she informed me that he was five weeks old, that she had given him a teaspoonful of paregoric, at 7 that morning, for a cold, shortly after which he fell asleep and remained so till half-an-hour previous to her bringing him, when she became alarmed at his prolonged sleep and the difficulty of awaking him. When first seen he was in a comatose state, skin cold and clammy, face pale, lips livid, eyeballs turned upwards, and pupils contracted. Some power of swallowing remained.

Some warm wine was poured down his throat, he was put into a warm bath, with a stream of cold water on his head, which considerably improved his condition; in addition to which a little strong tea was given, and mustard applied to the stomach, whilst slapping the feet and buttocks was frequently resorted to and always with advantage.

Under this treatment, and constant watching during the night, recovery took place.

The case is interesting from exact quantity given and time of administration being known, for on measuring the teaspoon in the presence of the mother, I found it contained just a drachm, which was given in about a teaspoonful of water at 7 that morning, just nine hours previous to his being brought to me, and I have no doubt had no treatment been employed, death would have ensued in about twelve hours.

I am, &c.

Aldershot, July 12, 1859.

PAREGORIC.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, JUNE 28, 1859.

F. C. SKEY, Esq. President, in the Chair.

A Paper by SIDNEY RINGER, Esq. was read,

ON THE CONNEXION BETWEEN THE HEAT OF THE BODY AND THE EXCRETED AMOUNTS OF UREA, CHLORIDE OF SODIUM, AND URINARY WATER, DURING A FIT OF AGUE.

The author commences his paper by a reference to the observations of Von Baerunsprung, Zimmermann, Michael Wunderlich, and others, on the temperature of the body during ague; and to the observations of Traube and Lockman, Redenbocker, Moos, and Hammond, on the excretion of urea, chloride of sodium, and water, during the fit. He then states that the object of the following paper was to trace out more particularly the connexion, if any, between the height of the thermometer and the excreted amount of these substances; and he then describes his method of investigation, and the precautions taken against sources of error. His observations were made on two untreated cases of ague (one of quotidian and one of tertian) in University College Hospital, under the care of Dr. Parkes; and they are recorded in a series of charts and tables, showing the following particulars:—1. The temperature of the body, as judged of by the thermometer, in the axilla (after the manner of Wunderlich), every quarter of an hour, for several hours before, during, and after the fit. 2. The hourly excretion of urea, before, during, and after the fit, in the first case; and the excretion according to stages, in the second case, as determined by the method of Liebig. 3. The hourly excretion of chloride of sodium and of urinary water during the same periods, in the first case; and the excretion by stages in the second. 4. The quantity of fluid drunk. The following are the results in the first case (quotidian):—The temperature of the body commenced to rise from forty-five to ninety minutes before any change was perceived by the patient, and continued to rise during the whole of the cold stage, and during part of the hot; it fell during the latter part of the hot and the whole of the sweating stage. The severity of the fit could be determined by the character of the rise, whether rapid or with oscillations, and by the variations of the temperature during the several stages; but the charts of temperature, and the comments given at length in the paper, must be consulted in order to exhibit this clearly.—The urea was found to increase during the fit, as stated by Traube. The increase commenced before the first feelings of cold, and before, indeed, the rise in the thermometer. The maximum increase of urea was at the end of the cold stage, or just at the commencement of the hot (*i. e.* before the temperature reached its highest point), and from this point the amount fell during the hot and sweating stages. There were variations in the amount of urea which closely corresponded to variations in temperature, but often preceded them a little. The amount of increase was considerable (from 200 to 500 per cent.), and was definite—that is, during five successive fits, the amount corresponding to each degree of temperature was the same, so that the temperature might be calculated from the amount of urea, or the reverse. A greater increase corresponded to a single degree at a high

than at a low temperature. The excretion of urea was not influenced by the excretion of urinary water.—The chloride of sodium was also increased, and varied with the temperature, but in a much less close degree. The increase was very considerable, and was at its maximum at the same period with the urea. The excretion of chloride of sodium was evidently much more closely connected with the excretion of water than in the case of urea. The urinary water was also definitely increased—*i. e.*, a certain quantity for each degree; and this was evidently independent of the fluid drunk. The amount of water drunk in no way influenced the total amount of water excreted. Much more was drunk than was excreted. The author next relates the observations made on the same patient when quinine was given. A scruple being given before the fit, and just as the temperature commenced to rise, delayed the rise for an hour, but had no other effect on the temperature on that day, and none on the urea, chloride of sodium, and water. Another scruple being given at night, after the fit, completely cured the patient, as far as subjective symptoms were concerned. On the following day he had no shivering, no warmth, and no sweating, and the temperature remained the whole day quite normal; yet the urea and chloride of sodium increased at the time they would have done had he had a fit. On the next day, the temperature was still normal, but the urea and chloride of sodium still rose during what would have been the fever hours; but the rise on this day was much less than on the day before. The effect of quinine, then, was to dissociate those two phenomena—namely, the temperature on the one hand, and the excretion of urea and of chloride of sodium on the other. The same fact has been noted by Redenbocker. The quinine affected the temperature at once, but the urea and chloride of sodium more slowly. In the second case (of tertian ague) the temperature followed the same laws. The urea, chloride of sodium, and water were determined only during each stage. There was found to be an increase in all three constituents, the increase being greatest during the cold stage. The urea was more than double the amount in the cold stage than in the previous apyretic hours. In this case charts are also given of the pulse, showing its close correspondence with the temperature. In addition to these cases of ague, the author subjoins one of hectic fever occurring in a phthisical patient of Dr. Walshe. The subjective phenomena were very similar to those of ague, as there was a well-marked cold, hot, and sweating stage. The temperature followed the same rules as in ague, and there was also an increase in the urea and chloride of sodium during the cold and hot stages. There was a difference in this respect, however, that the urea fell before the rise in the temperature commenced, and that its increase afterwards was even less than in ague. It also rose again just at the end of the sweating stage. So that, in spite of the diversity, of course the phenomena would appear to be very similar in ague and hectic fever. The author concludes his paper with a series of conclusions, recapitulating all the results to which his observations have led, and which have been given generally in the above abstract.

EPIDEMIOLOGICAL SOCIETY.

MONDAY, June 6, 1859.

Dr. BABINGTON, President, in the Chair.

A paper, by H. CAMERON, Esq., was read by Dr. McWILLIAM, entitled,

PRACTICAL REMARKS ON "CHOLERA MORBUS," ITS ORIGIN, NATURE AND TREATMENT, WITH CASES.

The author, after adverting to the multiplicity of views held by the Profession with reference to the cause, nature, and treatment of cholera, advanced the opinion that this disease was caused by a poison existing in the atmosphere, and that it was not contagious, but that it required a certain condition of the system to bring it under the influence of the choleraic poison. He considered that the great source of error in reasoning upon the nature of cholera, was mistaking the effect for the cause of the disorder. Vomiting and purging are present, and are caused by cholera, it is true; but they are not cholera itself, any more than are the peculiar state of the blood, and the cramps, by which this disease is characterised.

Cholera is considered by Mr. Cameron a disease in which the nervous system, and it alone, is engaged, and upon which the cholera poison acts, so as to produce spasms, and the other symptoms of cholera. In support of this view, he says that "post-mortem" investigations have revealed no morbid appearances of the viscera; and that it is only by microscopical examination, that the phenomenon of the minute vessels of the intestines being open-mouthed, from having lost their contractile power, has been discovered—accounting for the absence of serum in the blood, and the peculiar rice-like appearance of the choleraic motions. If, adds Mr. Cameron, it be admitted that the nervous system is really the seat of the disease, we have advanced one great step in the inquiry, which leads to a rational method of treatment. The tremendous shock which the nervous system has sustained, is to be met and combated, its effects remedied, and vitality, which is at its lowest ebb, restored. Mr. Cameron considers that chloroform by inhalation is capable of accomplishing these ends. He also recommends the internal administration of chloroform, with camphor mixture and ammonia; but his chief reliance is on chloroform by inhalation.

A discussion followed the reading of this paper, in which Drs. Babington, Murchison, Greenhow, Camps, and McWilliam took part.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.—JULY 28.

MEDICAL ACTS AMENDMENT BILL.

Mr. WHITESIDE having moved that the House resolve itself into committee on this Bill,

Sir E. GROGAN moved the adjournment of the House.

On a division, the numbers were—

For the adjournment	63
Against it	91

Majority —28

The Bill was then postponed.

On the 1st inst.

ADULTERATION OF FOOD AND DRINK.

The order for the second reading for this Bill was discharged on the motion of Mr. SCHOLEFIELD.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at a meeting of the Court of Examiners on the 29th ult., viz. :—

BRINGLOE, JOHN, Camberwell.
 CAMPBELL, JOHN, Kinnell, Kincardineshire.
 DELMAR, STUART, Canterbury.
 O'BRIEN, DANIEL, Calcutta.
 PARSONS, FREDERICK JAMES, Bayswater.
 PIERCEY, WILLIAM LEWIS, Dublin.
 SHANLEY, LUKE PATRICK, Strokestown, county of Roscommon.
 THOMSON, ALEXANDER BRENNER, Rothes, Morayshire.

Also on the 1st inst. :—

BRYANT, CHARLES, Sydney.
 BOSSY, ALFRED HORSLEY, L.S.A. London.
 DIXON, GEORGE, Helmsley, Yorkshire.
 EARDLEY, JOHN, L.S.A. Charles-street, Westbourne-terrace.
 EARNSEAW, JOHN, Oldham.
 ENGLEHEART, STEPHEN PAUL, Blackheath.
 FAWTHROP, JOHN, Queen's Head, Halifax, Yorkshire.
 HARRIS, WILLIAM HENRY, L.S.A. Baltic-house, Fimlico.
 KENNY, JOSEPH, L.S.A. Stoke Newington.
 PALMER, HENRY, East Garsten, Berkshire.
 NICHOLSON, JOHN LEE, L.S.A. Hull.
 SMITH, JOHN RICHARD, L.S.A. Cirencester.
 SMYTHE, HENRY, L.S.A. King's Lynn.
 SWINDELL, JOHN JOSEPH, L.S.A. Whetstone.
 TURNBULL, WILLIAM, L.S.A. Euston-road.

The following members of the College having undergone the necessary examinations, were admitted Licentiate in Midwifery at a meeting of the Board on the 2nd inst. viz. :—

BROCK, WILLIAM KORTRIGHT, Clifton.
 CULLEN, PETER, Calcutta.
 DAY, WILLIAM WHITE, Clifton.
 DOWKER, FREDERICK WOODCOCK, Layethorp.
 HERBERT, BENJAMIN HEYWOOD, Edgbaston, near Birmingham.
 JOYCE, THOMAS, Stamford-hill.

MENZIES, JAMES IRVINE, Upper Stamford-street.
 OLIVER, SOMMERVILLE, L.R.C.S.E. Edinburgh.
 TREND, THEOPHILUS WILLIAM, Bridgewater.
 WILDBORE, DANIEL HENRY GEORGE, Charlotte-street.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, the 28th July :—

ASHBY, JOSEPH FRANCIS, South Newington, Oxfordshire.
 DALY, MICHAEL, Ireland.
 DOWKER, FREDERICK WOODCOCK, Laysthorpe, Yorkshire.
 EDWARDS, DAVID RICHARD PERKINS, Newport, Monmouth.
 HARRISON, REGINALD, Stafford.
 HERLEBY, DANIEL POWER.
 ROBERTS, GRIFFITH WILLIAM, Clynnog, Carnarvon.
 WALES, JOHN, Downham-market, Suffolk.
 WILLIAMS, WILLIAM JOSEPH, Uffculme, Devon.

The following gentlemen also on the same day passed their First Examination :—

BRUNTON, LINTON BENNETT, Waterloo-place, Limehouse.
 CASE, GEORGE HENRY, Fareham, Hants.
 DAVEY, ALEXANDER GEORGE, Walmer, Kent.
 EVERETT, BENJAMIN GEORGE, Warminster, Wilts.
 HALL, AUGUSTUS ROBINSON, Topsham, Devon.
 HAMMOND, FRANCIS JAMES, Sherborne, Dorset.
 HAWKINS, THOMAS HENRY, Reading, Berks.
 SUTTON, HENRY GRANT, Ilminster, Somerset.
 WATKINS, WALTER, Castle-street, Brecon.
 WICKHAM, WILLIAM, Tetbury, Gloucestershire.

UNIVERSITY AND KING'S COLLEGE, ABERDEEN.—July 29th, 1859.—The following, after examination, had the Degree of M.D. conferred on them :—

BARTLET, ALEXANDER HENRY.
 BENNETT, THOMAS JARVIS.
 CARTER, HENRY FRULAND.
 EVANS, MAURICE GRIFFITH.
 FULLER, THOMAS.
 GILBERTSON, JOSEPH BRAY.
 GUPPY, THOMAS STOKES.
 HAY, WILLIAMS BANKS.
 HAYNES, JOHN ALFRED.
 HILLS, WILLIAM CHARLES.
 HOLL, HARVEY BUCHANAN.
 HOPTON, GEORGE OCTAVIUS.
 JONES, ALFRED.
 MILLER, JOHN WILLIAM MOORE.
 NOBLE, THOMAS.
 O'NEILL, WILLIAM.
 PINCHARD, BENJAMIN.
 SKEEN, WILLIAM.
 TODD, GEORGE SMITH.
 WEBB, JOHN WHITEMAN.

Also, the following had the Degree of M.B. conferred on them, after Examination :—

BROTCHIE, ALEXANDER RAINY
 MOIR, WILLIAM.

LIST OF OFFICERS reported qualified for the office of Assistant-Surgeon in the Army of India, by the Board of Examiners, arranged in order of merit. July, 1859.

EDWARD WALLIS, M.R.C.S.E.
 CHARLES CAMERON, M.R.C.S.E.
 JOHN MACLEOD CAMERON, F.R.C.S. Edin.
 JOHN RICHARDSON, M.B., F.R.C.S. Edin.
 ALBERT PARKER HOLMES, M.D., F.R.C.S. Dublin.
 M. J. S. PERREAU, M.R.C.S.E.
 ROBERT GRAY, M.B., F.R.C.S. Edin.
 J. MACNAGHTEN FLEMING, M.D., and Coll. Surg. Glasgow.
 C. F. OLDHAM, M.R.C.S.E.
 E. A. FITZGERALD, M.R.C.S.E.
 GEO. HENDERSON, M.D. and R.C.S. Edin.
 JOHN REID, M.R.C.S.E.
 PETER CULLEN, M.R.C.S.E.
 JAMES R. JOHNSON, R.C.S. Dublin.
 ISAAC NEWTON, M.R.C.S.E.
 B. T. SUFFREIN, M.R.C.S.E.
 C. H. LIVINGSTONE, F.R.C.S. Edin.
 J. F. BARTER, F.R.C.S. Edin.
 JOHN FITZGERALD, R.C.S. Dublin.
 A. N. HAJEL, R.C.S. Dublin.
 ANDREW FERGUSSON, M.D., F.R.C.S. Edin.
 HUGH GRIFFITH, F.R.C.S.E.
 SPENCER MEREDITH, M.R.C.S.E.

DEATHS.

LEACH.—July 15, at Martock, Somerset, Robert Leach, Esq., M.R.C.S., aged 33.

VALLANCE.—July 27, at his residence, Brighton, after a long and painful illness, Benjamin Vallance, late Surgeon to the Sussex Hospital.

WILLIS.—July 29, suddenly, after a long and painful illness, Francis Willis, M.D., of Shillingthorpe-house, in the county of Lincoln, aged 67.

The sum of £7949 sterling has this year been voted by Parliament towards the expenses of Dr. Livingstone's Zambesi expedition.

THREE HUNDRED AND FIFTY persons were admitted into Charenton during 1857 and 1858; and in 102 of these the cause of the madness was attributed to "drinking."

At the late sale of Lord Northwick's pictures was sold, for eighty guineas, a picture by Hogarth of Dr. Lock, founder of the Lock Hospital, a plan of which he holds in his hand.

In the Report on the Militia, just issued, we find that several memorials of adjutants, *Surgeons*, quartermasters, and paymasters are thrown aside, with a hint that this memorialising is hardly consistent with discipline.

WELLINGTON 'ON SOLDIERS' DIET.—"I look upon it that all men require two pounds' weight of food a-day; the English not more than the French. Vegetable food is less convenient than animal food, the last walking with you."

A BILL has just been introduced into Parliament to relieve certain of the Medical Corporations of the country from the imposition of the stamp-duties upon their diplomas; and also to regulate the proceedings of hawkers and pedlars!

THE PRINCE OF WALES has presented to Mr. J. R. Holman, Surgeon, R.N., serving in the *Osborne*, and specially appointed to attend upon his Royal Highness on his voyage home from Gibraltar, a valuable gold ring set with diamonds.

THE VAGINA AND ACTUAL CAUTERY.—Dr. Auscliner relates three cases of serious contraction of the vagina, which have fallen under his own observation, resulting from the employment of the actual cautery. In one case the canal was completely obliterated. The lessons taught by M. Jobert seem to have been well appreciated by his countrymen.

M. RAYNAL informs the Academy, that there exists among fowls a cutaneous affection, which is caused by a peculiar animal, *Sarcipsis mutans*; that this affection resembles the symptoms of itch, and is communicable to man, and to the horse and other domestic animals, and also from fowl to fowl.

ACCORDING to M. Gubler, the urine of albuminous patients contains notably more albumen after digestion, than after fasting. The quality of the food also has a marked influence over the production of albumen in the urine. This vegetable, whenever it is possible, should always predominate over animal diet, especially in cases of acute albuminuria.

THE JERKING RESPIRATION, according to M. Bourgade who has lately investigated this physical sign, is not pathognomonic of commencing tubercular disease of the lungs; but when the rational and general signs of the commencing disease are present, and the jerking respiration is at the same time audible, we may conclude with certainty that phthisis exists in its commencing stage.

"It is all very well," says M. Velpeau, "to point out charlatanism to the public authorities, and to claim the application of the law to charlatans. But when it happens, that persons in high places, on whom depend the application of the laws, are themselves the clients of the charlatans, what is the use of our reclamations? If the high administrating power has a peculiar taste for charlatancy, what avails it that we should put ourselves to the useless trouble of attempting to suppress it?"

INCREASE OF POPULATION.—According to the quarterly return of the Registrar-General for April, May, and June, 1859, as the births amounted to 175,727, and the deaths to 105,778, the natural increase of the population of England and Wales was 69,949; or, on an average, 769 daily. The natural increase of population was unusually great; and in the United Kingdom probably exceeded 1153 daily.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—The Library will be closed from Monday, August 15, until Saturday, September 10, both days inclusive. Books taken out by Fellows of the Society previous to August 15, will be allowed to remain in their possession during the time the Library is closed; any work particularly required by a Fellow during the same period, may also be had on the third day after special application by letter addressed "To the Honorary Librarian, 53, Berners-street."

ELECTION OF PHYSICIAN TO THE LONDON HOSPITAL.—A special general meeting of the Governors of this Institution was held on Wednesday, for the purpose of electing a Physician of the Hospital. Dr. John Langdon Haydon Down, of the Asylum for Idiots at Earlswood, and Dr. Jabez Spence Ramskill offered themselves for the post; but prior to the election Dr. Down retired, and the choice of the Governors consequently fell upon Dr. Ramskill.

CHOLERA AND CHOLERINE AT PARIS.—Considerable alarm has been felt at Paris, under the idea that the cholera has reappeared. It is true that during the great heats a great number of cases have occurred, and several patients have been rapidly carried off. Cholerine, too, prevails on a large scale. Still the disease has not manifested the character of an epidemic; and there can be little doubt that this sporadic cholera will disappear, as the unusually high temperature of the last few weeks has abated.

A few days ago there were interred in Tyldesley churchyard, the remains of a very useful, ingenious, but somewhat eccentric person, named Richard Halliwell, who for half a century practised dentistry, along with many other descriptions of business. Among his peculiarities, he willed in due testamentary form that the whole of the teeth extracted by him should be buried with him. In deference to his wishes his executors saw that done, and in the grave in which he lies were deposited 30,000 (64 lbs. weight) human teeth of his own extraction in the period mentioned.—*Leigh Chronicle*.

POISONING BY PHOSPHORUS.—M. O. Réveil sums up his researches on this subject:—1. The increase of cases of poisoning results from the facility with which the preparations of phosphorus can be obtained. The simplest means of remedying the evil is to substitute the use of the red phosphorus, which is not poisonous, for that of ordinary phosphorus. 2. Phosphorus finely divided, as when dissolved in fats, is absorbable. And it is easy to prove the presence of it in organs which it may have entered by absorption. Magnesia acts well in combating poisoning by phosphorus.

A NEW SPECIES OF MADNESS.—M. Boismont describes a new way some people have of exhibiting their mad fancies. He calls it the "Striking Mania;" for the individual so affected have an insuperable inclination to hit right and left at everybody about them. M. Delasiauve has seen many similar cases. They are connected with epilepsy. M. Géry relates that one of the principal orators of the Chamber of Peers (in France) had this "striking mania." This Peer always suffered in his abdomen, and during a conversation he always struck at those who approached him. His Physicians attributed this proceeding to intestinal irritation.

APOTHECARIES' HALL OF IRELAND.—At the annual meeting, held on the 1st of August, the following officers were elected for the ensuing year:—*Governor*—William Madden, jun., M.D. *Deputy-Governor*—Christopher Shaw, Esq., M.R.C.S.E. *Court of Examiners* (with the Governor and Deputy-Governor)—John Betty, M.D., Edward H. Bolland, M.D., Thomas Collins, M.R.C.S.E., Charles Holmes, M.D., Charles H. Leet, M.D., William Madden, M.D., John McMunn, M.D., William D. Moore, M.B., Robert Mulock, M.D., Henry P. Nolan, M.D., George B. Owens, M.D., Jerome O'Flaherty, Esq., M.R.C.S.E., John Shea, M.D. *Secretary*—Dr. Leet.

M. VAN HOLSBECK has a very simple method for arresting the secretion of milk. He says that it never fails, and that he has used it for more than three years. "I introduce into the end of a goose-quill a quantity of metallic mercury, closing the ends of it with sealing-wax. The woman suspends this little instrument in front of the sternum, and in less than twenty-four hours the secretion of milk ceases entirely; the breasts two days afterwards taking their natural size!"

THE DÉBRIS OF WARFARE.—Milan has a very singular aspect at this moment. The wounded who had been accumulated here, are in great part growing well, and those who had been attended to in the Hospitals of Bergamo, Brescia, and Como, and who are also recovering, have been sent here en route for France. Owing to these circumstances we have now in this capital about eight or ten thousand wounded, to be met with in the streets, the cafés, the restaurants, everywhere in fact. These people are clad in various uniforms;

they are more or less injured; they are wrapped up in bandages; they are supported in some instances upon crutches; their faces are pale, but full of the animation of returning life, and of pleasure inspired by the attractions of a large city. They give, as you may imagine, a strange air to the place. We might suppose that a fantastic carnival was being celebrated, if at each step we did not hear the names of Marignan, Magenta, and Solferino. The presence of these wounded men would be almost an accusation, in this discontented city, if the inhabitants did not display towards them the utmost deference, so as to conceal their real feelings. The poor fellows hobble along, accordingly, utterly ignorant of the unfavourable impression created by the peace of Villafranca.

PATHOLOGICAL SOCIETY OF EDINBURGH.—The Pathological Society of Edinburgh held a meeting of Council in conjunction with the Society on Friday, the 22nd July, Dr. Horton in the chair. The report of the secretaries was read by Mr. Brown (assistant secretary), and approved of. The treasurer's accounts and vouchers were then laid before the meeting, from which reports we learn that the finance of the Society, as well as its other affairs, are in the most favourable state. Dr. J. A. B. Horton then delivered a short farewell address for the present session, and after a vote of thanks was returned to the office-bearers for the past session, the next meeting was fixed for the second Thursday in November.

LOVE AND MADNESS.—Are these two epithets, as the vulgar saying goes, really synonymous? M. Devergie related to the Academy of Medicine the following case of what he called Transitory Madness:—A young man murdered his mother-in-law, a young woman. He is acquitted, and goes to Belgium. Never either before or after the proceeding, or during the trial, did the young gentleman exhibit signs of unreason. Two years afterwards he returned to France, and blew out his brains on the tomb of her whom, as he wrote, he had so much loved! M. Devergie calls this man mad. We should in this country, though probably not without difficulty, have hanged this youth, who evidently felt towards his mother-in-law as Don Carlos towards his.

ANTIDOTE TO STRYCHNINE.—Dr. Bewley, wishing to kill a mangy cur, and having read in Magendie's "Report on Strychnia," that the sixteenth of a grain will kill the largest dog, determined to make sure of this very little animal by giving it about half a grain. But either Magendie's statement was incorrect, or the drug was adulterated, for at the end of ten minutes the dog, though suffering frightfully, was not dead. Dr. Bewley resolved to put him out of his misery at once, and accordingly mixed half a drachm of prussic acid with a little milk, and put it under the dog's snout. He lapped the milk with avidity, and in less than a minute vomited, got upon his legs, ran away, and recovered.—*Literary Gazette.*

SATURNINE TREATMENT OF PHTHISIS PULMONALIS.—M. Beau has invented the use of carbonate of lead as a remedy in this disease. He gives it in pills of ten centigrammes; beginning with one and increasing them up to eight per diem. When the remedy produces its physiological or toxic effects, he stops its use. He has given it in five cases, and in four he states that the cough and expectoration were notably diminished. In one patient the toxic effects were produced in a month. Two principal reasons brought him thus to use the lead,—one theoretical, and one practical. The first is,—That anæmia is one of the consequences of saturnine poisoning, as well as of intermittent fever; and that these conditions are (or are said to be) incompatible with phthisis. The second is,—That workmen who handle lead rarely are affected with consumption.

THE LATE QUEEN OF PORTUGAL.—On July 11, Her Majesty accompanied the King to Vendas-Novas, in order to witness some experiments on rifled cannon. The heat was quite intolerable, and there was scarcely any shade on this sandy plain. Soon after her return to the palace she complained of indisposition, which was attributed to a slight *coup-de-soleil*, but it soon put on all the characters of a cynanche. Every attention was lavished upon her by Dr. Gomez and Baron de Silva, but by the 16th the symptoms had become excessively alarming. Dr. Symas, who enjoys a great reputation in throat diseases, was called in, but without avail, and in the evening the case was declared to be hopeless.

The celebrated surgeon, Barbeza, practised a very painful operation (tracheotomy?) on the throat in vain, and the unfortunate princess expired in the course of the evening.

It is asserted that Surgery is completely unknown among the Chinese. There is no such thing as an indigenous Surgeon to be found in the vast empire of China (excepting those who have been educated among foreigners.) There is not a Doctor capable of performing the smallest operation. There are so such things as Surgical instruments. The treatment of fractures and dislocations is completely unknown. Even a tooth is not taken out, unless it has become so detached that it may be removed by the fingers. Foreign Surgeons, who operate for cataract, remove tumours, cut for stone, amputate legs, etc., are compared to gods. Everything relating to midwifery is, and has been from time immemorial, in the hands of midwives; the ladies raise their hands in astonishment to Heaven at the bare idea of a man assisting at an accouchement.—*L'Union Médicale.*

THE FOOD OF HYSTERIC.—M. Sales-Girons says that he has lately seen in the Pyrenees, at Pierrefitte, a young woman, eighteen years old, very thin, who has not been able to stand for nine months. Three or four times she has been seized with syncope during an hour or two. Every evening at eight o'clock, she falls off into a profound sleep, without any convulsive movements. Her menses have ceased. For three months she has only eat one apple during the day, and during this time has passed no evacuation. All treatment has hitherto failed to alter her condition. M. Briene de Boismont hereon remarks, that defective alimentation is a thing common enough in young hysterical persons and lunatics. He knew a young female, who, during two months, took only two spoonfuls of soup a day. It is not at all uncommon for hysterical patients to have a motion only every two months!

THE ACTION OF GASES INJECTED INTO THE TISSUES OF LIVING ANIMALS has been investigated by M.M. Lecomte and Demarquay. They found that air, nitrogen, oxygen, carbonic acid, and hydrogen, do not occasion any injurious effect when introduced into the sub-cutaneous cellular tissue or into the peritoneum. That all these gases are absorbed after a longer or shorter period—carbonic acid in forty-five minutes, and nitrogen after several weeks. As regards rapidity of absorption these gases stand thus: carbonic acid, oxygen, hydrogen, air, nitrogen. That any gas thus injected invariably determines an exhalation of the gases contained in the blood and the tissues; in fact, absorption does not begin until the injected gas is mixed with the other exhaled gases. That generally the exhalation of the gases of the blood is greater during digestion than during fasting. That of the gases injected hydrogen determines the greatest amount of exhalation of gases from the blood. That the rapidity of the absorption of gases into the blood is not always in relation to their solubility in water.

UNIVERSITY COLLEGE, LONDON.—The result of the examinations at the close of the Summer Term for the Medical and Chymical Classes of the College was announced on Wednesday, the Dean (Professor Williamson, F.R.S.) in the chair, as follows:—Practical Chymistry (Professor Williamson, F.R.S.).—Gold Medal, Edward Lloyd H. Fox; Certificates—2d, J. Talfourd Jones; 3rd (equal), Isidore B. Lyon and Thomas Wemyss Bogg; 4th, Frederick George; 5th, Thomas Griffiths. Materia Medica and Therapeutics (Professor Garrod, M.D.).—Gold Medal, John H. Hutchinson; 1st Silver Medal, William Watson; 2nd Silver Medal, J. Starkey Smith; Certificates—4th, Palemon Best; 5th (equal), Frederick T. Roberts, and Henry C. Bastian; 7th, Thomas Griffiths; 8th, Thomas Wemyss Bogg; 9th, William Henry Brotherton; 10th, John Penning Baker; 11th, Warner Atkinson; 12th, Arthur W. Nankivell; 13th, George B. Phillips. Medical Jurisprudence (Professor Carpenter, M.D.).—Gold Medal, Edmund Holland; Certificates—2d, William J. Hunt; 3rd, Alfred Woodforde; 4th, William Clifford King. Midwifery (Professor Murphy, M.D.).—Gold Medal, John Celestin Bernard; 1st Silver Medal, William P. Rawlins; 2nd Silver Medal, M. Oscar Hurlston. Certificates—4th, George B. Phillips; 5th, Richard M. Miller; 6th, John M. Waters; 7th, Edwin Furse; 8th, Henry Sutcliffe; 9th, F. William Gibson; 10th, Donald Fraser Yeates. Ophthalmic Medicine and Surgery (Professor Wharton Jones,

M.D.).—Silver Medal, Isidore B. Lyon; Certificate, Alfred Woodforde. Botany (Professor Lindley, Ph.D.).—Senior Class Gold Medal, Thomas Wemyss Bogg; Silver Medal, Thomas J. Denman; Certificates—3rd, George Wilson; 4th, John H. Hutchinson; 5th, Edward Thomas Tibbits; 6th, Frederick Thomas Roberts, Dr. Fellowes's Medico-Clinical Medals.—Winter Term; Gold Medal, Philip Sydney Jones.

OUR WATERING PLACES.—In his last "Quarterly Returns," the Registrar-General gives the following statement of the rate of mortality in the Districts containing some of the principal English Watering Places:—

DISTRICTS.	Population, 1851.	Annual Rate of Mortality to 1000 living in the	
		10 Years 1841-50.	3 Months ending June 30, 1859.
Tunbridge (including Tunbridge Wells) ..	28,545	20	17
Thanet (including Ramsgate and Margate) ..	31,798	19	18
Dover	28,325	21	17
Hastings	21,215	18	14
Eastbourne	8,347	15	17
Brighton	65,569	21	19
Worthing (including Littlehampton and Arundel) ..	18,746	17	19
Isle of Wight (including Ryde, Newport, and Cowes) ..	50,324	17	16
Mutford (including Lowestoft)	20,163	17	16
Yarmouth	26,880	23	20
Weymouth (including Melcombe Regis) ..	22,037	19	18
Newton Abbott (including Dawlish, Torquay, and East and West Teignmouth) ..	52,306	19	17
Barnstable (including Ilfracombe)	38,178	17	14
Bath	69,847	24	21
Clifton (including part of Bristol City and Bristol Workhouse)	77,950	23	20
Cheltenham	44,184	20	19
Upton-on-Severn (including Malvern) ..	18,070	18	19
Warwick (including Leamington)	41,934	20	17
Asborne, Bakewell, and Chapel-en-le-Frith (including Buxton and Matlock)	62,308	20	23
Scarborough	24,615	21	19
Whitby	21,592	21	26
Kendal	38,572	20	19
Aberystwith	23,753	18	24
Bangor	30,810	21	24
Anglesey	43,243	17	13

STATE OF THE PUBLIC HEALTH.—The Registrar-General says: About 105,778 persons died in the three months which ended on June 30th, for that number appears on the registers of the quarter; and the rate of mortality was 2.153 per cent. or less by .061 than the average rate of the season. In the chief towns the mortality was at the rate of 2.238 per cent. less by .140 than the average of 2.378 per cent. In the districts of the country and of the small towns the mortality was lower (2.061) than it was in the denser districts; but instead of improvement there is deterioration. Indeed the sanitary condition of the country districts around the large towns now demands strict attention. The mortality of all England, if the same as in the 63 healthy districts, would be at the rate of 17 in 1000, or exactly 84,207. These may for the present be held to be natural deaths; the excess of 21,571 over this number are undoubtedly unnatural deaths, and may be ascribed to the unfavourable sanitary conditions in which a large portion of the population still lives. The 105,778 deaths in the quarter, although less than the usual number, imply, according to the most reliable returns of sickness, that about a million and a quarter of a million of people of all ages were, on an average, infirm or constantly sick during the season. The quarter of a million sick would be healed by effective sanitary arrangements. Thus, much labour that is now lost would be productive, and lives of great value would be saved. The whole community would acquire fresh strength and vigour. Money which is expended on real sanitary measures, such as have been carried out in Ely and a few other places, is the most profitable of all national investments; for it is an augmentation of the power and of the productive life of the population.

PARTIAL INSANITY ACCOMMODATED WITH PARTIAL PUNISHMENT.—A young man, 19 years old, at College in France, runs a sword through the neck of a fellow student sleeping in the same dormitory. Is he mad? He is taken to the

prison at Aix, and thence transferred to Lunatic Asylums at Marseilles and Montpellier, in order that his mental state may undergo close investigation. He is found to have an "agreeable exterior," and to have been always irreproachable in his manners, in his studies, and general conduct. But sometimes he had strange ways; and shortly before the catastrophe aforesaid, he was found to be somewhat abstracted and reserved. His religious zeal was at one time weaker and then stronger; at one time he would become much attached to one of his fellow students, and then take a dislike to him—and such was the case with the youth he killed. After the murder he ran away; but the day after gave himself up, and declared himself guilty. He gave no explanation of his conduct. An invincible power paralysed his reflection. All he knew was, that in an incomprehensible fit of jealousy, he sacrificed his idol, that no other person might enjoy intimacy with his friend. At the Assizes, the President enjoined the jury not to embarrass themselves in a scientific labyrinth, but to judge the questions according to common sense, without paying attention to the declarations of the "Experts." The jury gave a verdict, in accordance with which the accused was condemned to fifteen months' imprisonment. The "Experts," MM. Aubanel and Cavalier, concluded that he was mad; that he had no moral freedom or responsibility. One believed that he was now recovered; the other, that his madness was only quiet for the moment. "The thing is simple enough," says M. Delasiauve, "if you will only distinguish the reasoning, syllogistic function, from the action of the sentiments and the ideas. A person may be under the influence of jealousy, etc., and may nourish an extravagant idea, without having all his moral manifestations, affections, and instincts deranged."

INOCULATION OF SECONDARY SYPHILIS.—[The following is a specimen of virtuous indignation expressed by the *Gazette Hebdomadaire*, and directed at M. Ricord. Some persons will think it senseless abuse. It at all events gives us an idea of the rancour felt by certain of his brethren towards M. Ricord.]—"What is glory, what is reputation, when it has error for its basis? What is a mere man in the face of science? What is the celebrity of this doctrine of his before an accomplished fact? The question here is one of false laws, which for more than thirty years have spread infection through the conjugal bed, and though the cradle; which have insulted virtuous women, fresh from the arms of husbands tainted with secondary symptoms, and then compelled to defend their honour against the accusations of his theory; which have sown discord in families: which have occasioned those numberless dead births, which frighten the accoucheur; which have poisoned the wretched mercenaries, who have fulfilled the duties of second mother; which have misled justice, and transformed the victim into the guilty. During twenty years, we say, despite of all the advertisements of daily observation, contrary to the authority of the most experienced Practitioners, contrary to multitudes of facts detailed in works, in theses, in pamphlets, in journals, led by systematic blindness, or by the impulse of a school, the author of this system has exposed science, humanity, morality, and the law itself, to these misfortunes, to these iniquities."

PRIZE QUESTIONS AT THE ACADEMIE DES SCIENCES FOR 1861.—The following is the subject for the "Grand Prix," proposed on the report of M. Milne-Edwards, "*The comparative anatomy of the nervous system of fish*. Numerous and important works have been composed on the nervous system of the different classes of vertebrate animals; but great uncertainty still exists with regard to the determination of several parts of the encephalon in fish, and at the present time we have but a very imperfect knowledge of the modifications which this apparatus may present in the various ichthyological families. The Academy especially directs the attention of competitors to these two points:—1. It desires that by means of a comparative study of the nervous centres, the combination of which constitutes the encephalon, the analogies and differences existing between these parts in fish, and the superior vertebrata may be rigorously demonstrated. And 2. That this investigation may be so conducted as to throw a useful light upon the zoological relations of different fish to each other, thus furnishing new bases for a natural classification of these animals." The question for the "Bordin Prix," as reported on by M. Brongniart, is as follows:—"Investigate the distribution of the vessels of the

latex in the different organs of plants, and especially their relations to or their connexion with the lymphatic or spiral vessels, as also with the fibres of the liber." The study of the lactiferous vessels was proposed as a prize by the Academy so long ago as 1833, and the notary was adjudged to an important work by Dr. C. H. Schultz, which has served as a basis and point of departure for other works, which have been written on the subject. Nevertheless there still exists great uncertainty concerning the real functions of these vessels in the life of plants, and upon the part they take in the circulation of their fluids. Of late, observations of great interest have exhibited intimate relations, and even connexions between these vessels and those destined for the ascent of the sap. If these observations admit of generalising, great light might be thrown upon the circulation of vegetable juices. The Académie is desirous that the subject should be more extensively investigated, and that it should be ascertained—"1. Whether these communications between two orders of vessels considered hitherto as completely independent can be placed beyond all doubt? 2. Whether such relations be a mere exceptional fact, peculiar only to certain plants, or whether they are to be found in all plants possessed of these two kinds of vessels? 3. Whether the connexions of the two orders of vessels exist in all the organs of the plants, or only in certain of its parts? 4. Whether there exist connexions of the same description between the vessels of the latex, and other tissues of the plants; such, for example, as the fibres of the liber. These anatomical researches may be completed by some physiological experiments suited to demonstrate the part which these vessels and the juice which they contain, perform in the economy of the plant. It is very desirable that the text of the essays should be accompanied, not only by drawings, but by some microscopical preparations, enabling the exactitude of the observations to be tested." The mémoires to be sent in before 31st December, 1860.

VITAL STATISTICS OF LONDON.

Week ending Saturday, July 30, 1859.

BIRTHS.

Births of Boys, 881; Girls, 922; Total, 1803.

Average of 10 corresponding weeks, 1849-58, 1485.0.

Amount of horizontal movement of air in the week	670 miles.

TO CORRESPONDENTS.

An important Lecture by Dr. Simpson is in type, but we had not received the proof at the hour of going to press.

R. T.—For the next M.D. Examination at St. Andrew's, see advertisement in this week's paper.

New Subscriber.—No. The powers of the University and College will not be affected by the Bill.

G.S.H.—The period of gestation of the hippopotamus has been fixed at fourteen months exactly, according to the periods of coitus and birth in the recent delivery at Paris.

X. Y. Z.—1. Messrs. Ash, Broad-street, Golden-square, W. 2. The Chemical Society meets at Burlington House. All information as to membership can be obtained from the Secretary. 3. Not complete.

Mr. Parkin's suggestion as to the use of charcoal as a deodoriser of sewage before it falls into the Thames, is worth consideration; but it is hardly necessary to publish the copy of his letter to the Metropolitan Board.

LADIES' SANITARY ASSOCIATION.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I beg to inform you that Dr. Southwood Smith and Dr. Farr have consented to become revising editors of the publications issued under the direction of the Ladies' Sanitary Association.

I am, &c.

M. A. BAINES.

MEDICAL TITLES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—If Lord Robert Cecil, Mr. Whiteside, or some other friend of half-fledged Medical bantlings, would instead of their proposed amendments to the Medical Act, endeavour to carry something to the following effect, they would really deserve well of their country. "And be it further enacted, that whosoever any person being otherwise entitled to be registered under the Medical Act, shall obtain from any one of the licensing bodies enumerated in Schedule A, its licence, degree, or diploma, in exchange for a money payment without submitting to and satisfactorily undergoing a fitting examination, such qualification when inserted in the Register, shall have placed after it the word 'Bought' in brackets; and the possessor thereof shall be required when assuming, in printing, or writing, or signature, the title professed to be derived from such licence, degree, or diploma, to add the word 'Bought' after the words or letters which may be used to signify such licence, degree, or diploma.—Ex. John Smith, M.R.C.S.E., L.R.C.P., Edin. (Bought)."

A simple provision of this sort would no doubt be hailed with gratitude by a number of gentlemen who have been recently put in the unfortunate position of appearing to sail under false colours; for it must be supposed to be very painful to them to know that they are running the risk of making the public believe that in reward for special attainments or protracted study, they have been specially honoured by having conceded to them a higher professional title or position, when they themselves are fully aware at the same time that such is not the case,—too often in fact rather the reverse. Every sensitive mind must feel that some mode of thus publicly clearing themselves is due to such gentlemen.

I am, &c.

SUUM CUIQUE.

Scarborough, August 1, 1859.

P.S.—Foot-notes in the Register might inform the public the price paid for the various qualifications in question, and thus their relative sterling values would be seen at a glance.

COMMUNICATIONS have been received from:—

Dr. SIMPSON; Mr. J. R. MARTIN; Mr. PEMBERTON, Birmingham; Mr. REDFERN DAVIES; Dr. GORDON; Dr. DAVIES, Bath; Dr. ROOKE; Mr. TODD; Mr. WALTON; Dr. HALDANE; Mr. HULKE; Mr. H. SMITH; REGISTRAR-GENERAL; Dr. WATERS; Dr. NOCGERATH, New York; Mr. R. BROWN; Mr. FLETCHER; Mr. MAUNDER; Mr. C. HUNTER; Mr. MAYSMOR; Mr. TIFFEN; Mr. RIVERS; Mr. WHEATLEY.

APPOINTMENTS FOR THE WEEK.

EXPECTED OPERATIONS.

King's College Hospital.—The following operations will be performed this day (Saturday):—

By Mr. Fergusson—Cleft Palate; Hare-lip; Fistula in Ano; Vesico-Vaginal Fistula.

NEPENTHE, OR ANODYNE TINCTURE

(OBTAINED EXCLUSIVELY FROM OPIUM),

PREPARED AT THE LABORATORY OF FERRIS, TOWNSEND, LAMOTTE, & BOORNE,
MANUFACTURING CHEMISTS AND WHOLESALE DRUGGISTS, BRISTOL.

This preparation has now been for many years extensively used by a large number of eminent members of the Medical Profession with the greatest success. It does not produce headache, stupor, giddiness, prostration of strength, constipation, or the usual unpleasant symptoms attending the use of other preparations of opium.

Nepenthe has frequently been found of essential service in cases of Cancer, where every other opiate has failed.

The following Testimonials received from Medical gentlemen in extensive practice will be regarded as satisfactory proof of its efficacy:—

MEDICAL TESTIMONIALS.

"Having prescribed your 'Anodyne Tincture' in many cases, I would strongly recommend its more general adoption. It is especially useful in the wakefulness common after parturition, or other unusual exertion or excitement. It produces a refreshing sleep, and I do not remember any case in which it has caused the objectionable effects of the other opiate preparations."

"S. Wellington-street, London-bridge, August 14, 1856.

"SAML. GRIFFITH, M.D. London, M.R.C.P.
Consulting Physician-Accoucheur to the Farringdon Dispensary,
Physician-Accoucheur to St. Thomas's Hospital, &c."

"Gentlemen,—I have great satisfaction in bearing testimony to the value of your 'Nepenthe,' in relieving suffering from disease, and in procuring sleep where ordinary narcotics fail or disagree. For several months I have found it very effectual in relieving a great sufferer when all the ordinary anodynes had ceased to benefit, and although the dose has not been increased for months, the relief is as complete.

"Nepenthe" is a very valuable addition to our means of relief, and the Profession and the public are greatly your debtors for it.

"I am, Gentlemen, yours obediently,

"EDWD. BECK, M.D. Cantab.
Physician to the East Suffolk Ipswich Hospital."

"To Messrs. Ferris & Co.

"Gentlemen,—'Nepenthe' has, for some time, been a favourite narcotic with me, and I infinitely prefer it to any preparation of opium now extant. It has proved a remedy of great value in all cases of Neuralgia, Chronic Rheumatism, Hypochondriacism, and indeed all affections where the use of a sedative is indicated; and in Delirium Tremens it is certainly invaluable, performing its operation upon the system, without leaving those distressing feelings consequent upon the use of opiates in general.

"I remain, Gentlemen, your obedient Servant,

"WILL. WOOD BRADSHAW, M.D. M.R.C.P. & F.R.C.S. Lond. &c. &c. &c."

Extract of a Letter from the late G. W. CAINES, Esq. M.R.C.S.

"Please to send me some 'Nepenthe,' as I have a patient with cancer in the breast, with whom no other preparation of opium agrees. I have tried them all."

"Uffculme (Devon), Feb. 16, 1854.

NEPENTHE may be procured direct from Messrs. FERRIS and CO., 4 and 5, Union-street, Bristol; from respectable Dispensing Chemists throughout the Kingdom; and from the following Agents:—

LONDON:—Mr. Thos. Keating, 79, St. Paul's-churchyard; Messrs. Evans, Lescher, and Evans, 60, Bartholomew-close; Messrs. Savory and Moore, 143, New Bond-street; Messrs. J. Bell and Co., 338, Oxford-st.

MANCHESTER:—Mr. James Woolley.

LIVERPOOL:—Messrs. Clay and Abraham; Messrs. Evans, Son, and Co.; Messrs. Clay, Dod, and Case.

BIRMINGHAM:—Messrs. Southall Bros. and Co.

YORK:—Messrs. Butterfield, Clarke and Co.

NORWICH:—Messrs. Smith and Sons.

PLYMOUTH:—Messrs. Balkwill and Co.

EXETER:—Mr. Geo. Cooper; Messrs. A. Evans and Co.

EDINBURGH:—Messrs. Raimes and Co.

As many imitations of Nepenthe have been attempted, the signature of FERRIS and COMPANY is placed over the cork of every bottle of the true preparation; and none purchased without this protection can be depended upon.

DR. DE JONGH'S (Knight of the Order of Leopold of Belgium) LIGHT-BROWN COD-LIVER OIL.

CAUTION.

Serious and repeated complaints having been made of a discreditable system pursued by many Chemists and Druggists of intrusively recommending or surreptitiously substituting a pale, yellow, or coarse brown preparation, when Dr. De Jongh's Oil is prescribed, the Medical Profession are respectfully and earnestly solicited to afford their assistance in counteracting and repressing a practice alike injurious to their patients and to the fair repute of a remedy now held in such high and general estimation. In all cases where this Oil cannot be procured from a respectable Chemist, application should be made to Dr. DE JONGH'S Agents,

ANSAR, HARFORD, & CO., 77, Strand, London, W.C.

By whom any quantity will be immediately forwarded.

WALTERS' INDIA-RUBBER URINALS.

F. WALTERS having originally invented these Urinals, begs to warn the Profession of the many bad and useless imitations which are now sold, and he would advise them, before purchasing, to look that they are stamped with his name; as, unless that be the case, he cannot guarantee them.

These conveniences are made for those who require them only occasionally, during a long journey, as well as for those invalids who use them always. Mr. WALTERS has much improved them by making them of *Etherised India-Rubber*, which adds very greatly to the strength of the India-Rubber, at the same time that it prevents its sticking together; by this means he is enabled to make them less stiff and harsh than hitherto, and yet to retain all the advantages of that stiffness. There is a patent valve, which prevents the return of the fluid; and they may be worn either sitting, walking, or lying, without the slightest inconvenience, and without being perceived by any one.

WALTERS' CONVENIENCES FOR LADIES will be found particularly useful during pregnancy. They are perfectly soft and flexible, and may be worn with perfect comfort.

All Orders must be accompanied by a Post-office order or reference.—Entrance for Ladies at the private door, where a Female attends.

MANUFACTURER OF ELASTIC STOCKINGS, BELTS, &c.

16, MOORGATE STREET, NEAR THE BANK, LONDON. E.C.

University of St. Andrew's.—Notice

is hereby given, that the next GENERAL EXAMINATION for the Degree of DOCTOR of MEDICINE will commence on MONDAY, the 17th of OCTOBER.

Fellows and Members of the Royal Colleges of Surgeons of England, Edinburgh, and Dublin, of the Faculty of Physicians and Surgeons of Glasgow, and Licentiates of the London Apothecaries' Company, are eligible for examination.

Every Candidate is required to communicate by letter with Dr. Day, the Professor of Medicine, fourteen days before the period of Examination, and to present himself to the Secretary for Registration on or before Saturday, the 15th of October.

By order of the Senatus Academicus,
St. Andrew's, August 1, 1859. JAMES M'BEAN, A.M., Secretary.

Sydenham College Medical School,

SUMMER-LANE, BIRMINGHAM (opposite the General Hospital).—The SESSION 1859 and 1860 will commence on TUESDAY, the 4th of OCTOBER next, with an INTRODUCTORY ADDRESS, at Three o'clock in the Afternoon.

Further particulars may be obtained on application to the Principal, Dr. Bell Fletcher, Waterloo-street; to the Treasurer, Dr. Russell, Newhall-street, who is authorised to enter Students; to the Secretaries, Mr. F. Jones, 42, Newhall-st., and Mr. Bassett, 1, St. Paul's-square, Birmingham.

Sydenham College, Summer-lane,

BIRMINGHAM.—MEDICAL TUTOR.—The Committee of Sydenham College are desirous of APPOINTING a MEDICAL TUTOR, to superintend the Education of the Students. Salary, £100 per annum.

Further particulars may be learned from the Principal, Dr. Bell Fletcher, 7, Waterloo-street, Birmingham, to whom applications must be addressed, not later than 1st September.

Asylum for the Imbecile and Insane,

at BENSHAM, NEAR NEWCASTLE-ON-TYNE.

Physician and Proprietor . . . Dr. GEORGE ROBINSON.

Resident Physician . . . Dr. DOUGLAS ROBERTSON.

There are now SEVERAL VACANCIES in this Institution, which is pleasantly situated, and commands extensive views of the surrounding country. For terms, &c. apply at the Asylum, or to Dr. Robinson, Newcastle.

Nervous and Mental Disorders.—Wyke

House, Sion Hill, Isleworth, Middlesex, a private establishment for the care and recovery of Ladies and Gentlemen mentally afflicted. Conducted by Mr. ROBERT GARDINER HILL, late Resident Medical Professor of Eastgate House, Lincoln, and by Dr. E. S. WILLET.

Mental Disorders.—Wye House,

BUXTON, DERBYSHIRE.—PRIVATE ESTABLISHMENT for the Care and Treatment of a select and limited number of persons mentally affected.

Resident Proprietor.—T. DICKSON, L.R.S.C.E.,

Late Medical Superintendent of the Manchester Lunatic Hospital.

Wye House is delightfully situated in its own grounds of twelve acres at Buxton, and forms part of the magnificent scenery of Wye Dale. The well-known salubrity of Buxton, and the hygienic effects of its waters and baths, renders it a desirable locality for Invalids Nervously or Mentally affected. Ample means are provided for the occupation and amusement of the Patients, including carriage and garden exercise.

Norwich Union Life Insurance Society.

Instituted 1808. Invested Capital exceeding £2,000,000 sterling. This Society is one of the very few purely Mutual Insurance Offices, the whole of the profits being divided among the Policy-holders, and possesses large reserves applicable to future Bonuses.

The rates are considerably below those usually charged. Thus, at the age of 40, the sum of £33 19s. 2d., which, at the ordinary premium, will insure £1000, with the Norwich Union

WILL INSURE ONE THOUSAND AND NINETY-FIVE POUNDS EIGHT SHILLINGS,

giving an immediate bonus in addition to subsequent accumulations.

Annuities and Special Risks undertaken on favourable terms.

Medical Fees paid by the Office.

For forms of proposal and prospectuses, apply at the Society's Offices, 6, Crescent, New Bridge-street, Blackfriars, E.C., and Surrey-st., Norwich.

Superphosphate of Iron and Super-

PHOSPHATE OF IRON and LIME. New Remedial Agents introduced to the notice of the Profession at the Meetings of the Medical Society of London, and now extensively employed by the most eminent members of the Medical Profession. The Syrup is the most eligible mode of administering these valuable Remedial Agents. Mr. GREENISH will be happy to forward a variety of cases which have been furnished to him, where its success has been most marked, and which will serve to indicate where it may be most advantageously employed.—20, New-street, Dorset-square.

H. Silverlock's Medical Label Ware-

HOUSE, Letter-Press, Copper-plate, and Lithographic Printing Offices, Wardrobe-terrace, Doctors'-commons, London, E.C.

H. SILVERLOCK'S stock of Labels for Dispensing purposes having been recently revised and enlarged, now consists of upwards of 800 different kinds. Yellow and Green Labels for Drug Bottles, Drawers, &c., at per book or dozen: a Book, containing a selection in general use in Surgeries or Dispensaries, 10s. 6d. Priced Catalogues of the above may be had, post free, on application. Printing of every Description at Moderate Prices.

Wines from the Cape of Good Hope.

W. and A. GILBEY'S SOUTH AFRICAN PORT, SHERRY, &c. &c., 20s. per Dozen. First growths only. Two samples for 12 stamps. Wine Importers and Distillers, 357, Oxford-street, London (W.); 31, Upper Sackville-street, Dublin; and 12, St. Andrew-square, Edinburgh. Medical Reports, Price Lists, &c. sent post free.

PURE SPIRITS FOR THE FACULTY.

S. V. R. 56 o.p., 17s. net Cash.—

This quotation admits of neither credit nor discount, and 1s. per gallon must be added for packages, to be allowed on their return.

HENRY BRETT and CO., Old Furnival's Distillery, Holborn.

Newbery's Cod-Liver Oil Cakes.—

"The gingerbread is extremely light and pleasant, the flavour of the oil being completely covered."—Medical Times and Gazette, 12th February, 1859. Packets, 1s. 9d. and 3s. F. NEWBERRY and SONS (Proprietors of the "PULVIS JACOBI VEE, NEWBERRY'S"), 45, St. Paul's-Churchyard, London. ESTABLISHED A.D. 1740.

S. Bowles, late Windsor & Co., Phial

and BOTTLE MERCHANTS, Dealers in Druggists' Sundries, &c., 6, James-street, Covent-garden, W.C. The cheapest house in London for every description of Medical Glass of the best quality.

Samples and Prices forwarded free on application.

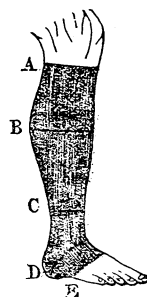

SUMMER DIET.

Brown & Polson's Patent Corn Flour.

—This is superior to anything of the kind known — LANCET. Obtain it from Family Grocers, or Chemists, who do not substitute inferior articles. It is preferred to the best Arrow Root; for Breakfast boiled simply with milk; Dinner or Supper, in Puddings, warm or cold, Blancmange, Cake, &c., and especially suited to the delicacy of Children and Invalids. Packets, 16 oz—3d.

Dr. Caplin's Electro-Chemical Bath

ESTABLISHMENT, 9, YORK PLACE, BAKER STREET, PORTMAN SQUARE, for the extraction of Mercury, and other Metallic or Extraneous Substances, and the Treatment of Chronic Diseases. For the demonstration of this new system, vide the Second Edition, price 1s., Svo, of Dr. Caplin's Treatise on the Electro-Chemical Bath, and the Relation of Electricity to the Phenomena of Life, Health, and Disease. Sold at the Author's Establishment.

Voullion's Patent Elastic SPIRAL SUPPORTS, "WITHOUT SEAMS OR LACING."

200 Leading Members of the Medical Profession recommend them in preference to all others.

DIRECTIONS FOR MEASUREMENT:—

For STOCKINGS—Circumference round the instep, ankle, calf, and above calf.

For KNEE-CAPS—Circumference below knee, at knee, and above knee.

For THIGH-PIECE—Circumference round top and bottom of thigh.

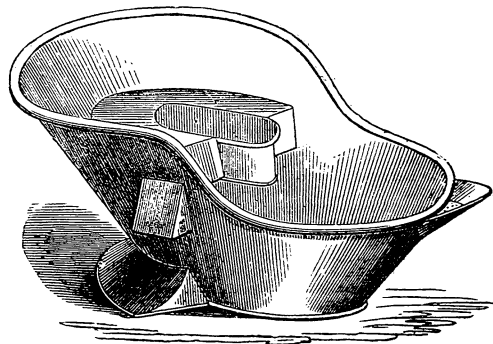

For ABDOMINAL SUPPORTS—Circumference of body above and below the hips.

Illustrated and Priced Catalogues free. Prices reduced 30 per cent.

MEACHER, Operative Chemist, sole Manufacturer, 105, Crawford-street, Portman-square.

Oxley's Patent Multum-in-Parvo Bath.

Sole Makers, GRIFFITHS and BROWETT, 63, BRADFORD-STREET, BIRMINGHAM; and to be had of all respectable Ironmongers.

The convenience of a Bidet, Sponge, Hip, Foot, and Nursery Bath are here combined, which renders it not only the best for general purposes, but indispensable for the Invalid, to whom it may confidently be recommended by members of the Medical Profession as the most comfortable and useful Bath extant.

MEDICAL AGENCY.

NOTICE OF REMOVAL AND CHANGE OF FIRM.

Mr. Lara (for the last eight years the sole representative of LANE and LARA, Medical Agents and Arbitrators and Lunatic Asylum Registrars,) begs to inform the Profession that, in consequence of the daily increasing support with which he has been favoured, and for which he tenders his sincerest thanks and acknowledgments, he has taken into PARTNERSHIP Mr. James Maxfield Walters, a gentleman who has had considerable experience in the business. It will, therefore, from and after Christmas, 1858, be carried on, under the Firm of LARA and WALTERS, at 6, PUMP-COURT, Middle Temple, E.C., whither they have removed their Offices from 22, Buckingham-street, Adelphi, in order to provide that larger accommodation which a constant intercourse with a great majority of the entire body of General Practitioners in England has rendered necessary.

Partnerships and Practices sold and valued: Asylums transferred: Arbitrations effected: Assistants provided (if for a permanence without charge to Employers): and every other description of business transacted for the Profession at a fixed and moderate cost. Attendance from 11 till 4.

The Family of the Late Mr. Milsom,

SURGEON, of COLLOMPTON (four of whom are totally unable to assist themselves) having been suddenly left in a state of the most utter destitution, I earnestly appeal to the charitable on their behalf.

R. PINCKNEY, Vicar.

Subscriptions received by the Rev. J. P. Sydenham, at the Devon and Cornwall Bank, and by the Rev. R. Pinckney, Colloampton.

Stourbridge Dispensary.—Wanted, a

HOUSE-SURGEON and SECRETARY. Salary, £120 per annum, with house and coals. Candidates must be Members of the Royal College of Surgeons and Licentiates of the Apothecaries' Company, London. The Gentleman elected will be required to enter into an agreement not to practise within three miles of the town until three years have elapsed after resigning the appointment. Applications and testimonials to be forwarded to Mr. Way, the present House-Surgeon, on or before the 20th day of August. The Election will take place the following Tuesday. Duties commence September 30th.—Stourbridge, July 11, 1859.

Northampton General Lunatic Asylum.

—HOUSE-SURGEON WANTED.—NOTICE is hereby given, that a SPECIAL COURT of DIRECTORS of the above Institution will be held on WEDNESDAY, the 31st day of AUGUST next, at One o'clock, to APPOINT a HOUSE-SURGEON. Candidates to be Members of the Royal College of Surgeons of England, and Licentiates of the Apothecaries' Company of London; also, not more than 25 years of age, and unmarried. Salary, £100 per annum, with apartments, board, and washing.

Testimonials and Diplomas to be forwarded to the Secretary, on or before the 22nd day of August next.

By order of the Quarterly Court,

The Asylum, July 29, 1859.

JOHN GODFREY, Secretary.

Manchester Royal Infirmary and

DISPENSARY. Weekly Board, July 25th, 1859.—WANTED, in consequence of a vacancy about to occur, an Unmarried Gentleman as PHYSICIANS' ASSISTANT to these Charities. Every candidate for the office will be required to produce a diploma from one of the Royal Colleges of Surgeons in London, Edinburgh, or Dublin, and be a Licentiate of the Worshipful Society of Apothecaries, London, or he shall be a Graduate of Medicine of the London University. The gentleman who may be elected will be required to remain in the situation for a term of not less than two years, to reside in the house, and devote the whole of his time to the duties of the office; which duties consist in visiting and prescribing for the home and out patients. Salary, 60 guineas a year, with board and lodging. Letters from candidates, with their diplomas and other testimonials, must be sent (free of charge) on or before Saturday, the 20th August next to the Secretary, at the Royal Infirmary.—By order of the Board,

ROBT. THORPE RADFORD, Secretary.

Addenbrooke's Hospital, in the Town

of CAMBRIDGE.—HOUSE APOTHECARY.—NOTICE IS HEREBY GIVEN, that a SPECIAL GENERAL COURT of the PRESIDENT and GOVERNORS of the above Institution, will be held in the Board-Room of the said Hospital, at Eleven o'clock in the forenoon of the 5th SEPTEMBER next, for the ELECTION of a GENTLEMAN, to fill the office of House Apothecary, vacant by the resignation of Mr. Edmund Carver. The Gentleman elected will have to reside, and will be boarded the Institution. The Salary is £86 a-year.

All Candidates must be duly qualified, and must forward Testimonials as to ability and character, sealed up, under cover, to the Secretary, before the 31st of August, and must produce their qualifications to the Court, on the day of Election.

And notice is hereby further given, that in case of a contest, votes will be received by the Court, at the Board-Room, from 12 o'clock at noon, until 5.30 o'clock in the afternoon of the said fifth day of September, when the Election will finally close.

Ladies only can vote by proxy, forms of which, and all particulars, may be had upon application, at the office of the Secretary.

By Rule 24 no Governor can be allowed to vote whose Subscription is unpaid; nor unless he has been a Governor for six months, except he be a benefactor of Twenty Guineas and upwards.

Annual Subscriptions became due on the 29th of September last, and as Subscriptions are paid in advance for the current year, all Governors by yearly subscription of two guineas must pay their Subscriptions up to the 29th September, 1859, together with all arrears, if any, to EDMUND JOHN MORTLOCK, Esquire, Banker, Cambridge, the Treasurer, before their votes can be received.

By order,

FREDERIC BARLOW, Secretary.

St. Andrew's-street, June 30th, 1859.

Medical Transfer and Partnership.

30, Bucklersbury, Cheapside.

Mr. Orridge, Medical Transfer Agent,

Referee, and Valuer of Medical Property, may be consulted, at the above Address, by Gentlemen about to receive PARTNERS, or to RELINQUISH or to COMMENCE Practice.

Mr. Orridge is known to many of the Hospital Physicians and Surgeons of London.

He has been concerned professionally for a considerable proportion of the most influential Practitioners (including Partners in many of the leading Medical Firms), to whom he has the satisfaction of being permitted to refer—a privilege that he trusts will be regarded as a proof of the sincerity of his endeavours to conduct these transactions in an honourable and straightforward manner.

Gentlemen desirous of obtaining Mr. Orridge's opinion, or requiring his attendance professionally in any part of England, can obtain terms on application, by (confidentially) transmitting name and address.

Office Hours, from Eleven to Four.

Saint George's and Saint James'

DISPENSARY.—The Offices of PHYSICIAN and ACCOUCHEUR to this Charity having become VACANT by the resignations of Dr. Brewer and Dr. J. L. Siordet, Candidates for the appointments are requested to attend with their Diplomas and Testimonials at the Dispensary, No. 60, KING-STREET, REGENT-STREET, on THURSDAY, the 11th instant, at Half-past Two o'clock p.m. punctually. Candidates for the Office of Physician must be either F. or L.R.C.P. London. Candidates for the Office of Accoucheur must be either L.R.C.P. London, or M.R.C.S. England. The Election of nominated Candidates will take place on Monday, the 15th instant, at Twelve o'clock at Noon.

August 1, 1859.

J. H. YORK, Secretary.

Salop Infirmary.—The Office of House

SURGEON to the above Institution will shortly become VACANT through the resignation of Mr. Dickin. Candidates are requested to declare their intentions of becoming candidates, and to send in their testimonials on or before the 18th day of August instant. No person is eligible for the office unless he be a Licentiate of the Apothecaries' Company in London, and a Member of the College of Surgeons of London, Dublin, or Edinburgh. The salary is £100 per annum, with board, washing, and residence in the Infirmary. Personal canvass of the trustees is not required or wished. By Order of the Weekly Board,

Board Room, July 30, 1859.

HENRY BEVAN, Secretary.

Insanity, Nervous Debility, &c. The

Medical Profession and the Friends of the Afflicted, are respectfully informed that they can be immediately supplied with Attendants, Male or Female, of Undoubted skill, experience, and respectability, on application to the LISSON GROVE ASSOCIATION OF ATTENDANTS ON PERSONS BODILY OR MENTALLY AFFLICTED. All Communications to S. BROOKES, Chemist, (Secretary,) 62, Lisson Grove, Marylebone, London, N.W., will meet with immediate attention; and by whom Ample Testimonials can be offered in favour of the Members belonging to the above Association. Established August 1st, 1840.

Mr. James Robinson, Dentist, has

REMOVED from No. 7 to No. 5, GOWER-STREET, Bedford-square, London, where he may be CONSULTED daily from 10 to 4.

5, Gower-street, Bedford-square.

In-door Assistant Wanted, in a

Provincial Town. A Gentleman possessing the Double Qualification, and duly registered, will be required to assist in Dispensing. Salary, £80 per annum. The most satisfactory references required. Address, Messrs. CORBYN & Co., 300, Holborn, London.

Wanted, a Situation, by a Young

Man, aged 20, to Dispense, Visit, and attend Midwifery. The North or Lancashire preferred. Address, Alpha, Post-office, Hounslow.

Medical.—An eligible opening occurs

for a YOUNG MAN wishing to commence Practice in a County Town in the South of England. Population, about 4,000. Owing to the sudden death of the late Practitioner, a small Premium only will be required, and an early application is requested. For Particulars address M. at the office of Woolmer's Gazette, Exeter.

A Gentleman, who has completed his

Apprenticeship, and part of his Medical Education, seeks a HOME with a MEDICAL PRACTITIONER, where his services would be considered wholly or in part an equivalent for his Board and Lodging, and time could be allowed for the necessary Hospital Courses. Address, C., Mr. Hemmens, Stationer, Penzance, Cornwall.

For Disposal, a General Practice of

Twenty years' standing, producing £400 per annum, including appointments. Purchase £250. Six months' introduction will be given. Convenient house, good stables, walled-in garden, and half-acre paddock, with spacious premises. Rent £30 per annum. Apply to G. Cubitt, 17, Market-place, Norwich.

London: Printed by CHARLES REED and BENJAMIN PARDON of 1, 2, and 3, Lovell's-court, Paternoster-row, in the City of London, and published by JOHN CHURCHILL, at the Publishing Office, No. 11, New Burlington-street, in the Parish of St. James, in the City of Westminster.—August 6, 1859.

NOTICE.

The Medical Directories for England, SCOTLAND, AND IRELAND.

The ANNUAL CIRCULAR has been posted to every Member of the Profession.

The Editors respectfully request that the Circular be returned with as little delay as possible.

Office: Mr. Churchill's, New Burlington-street, W.

YEAR-BOOK OF STATE MEDICINE.

Mr. Churchill announces to the Profession and the Public, that on the 1st of January next will appear the First Annual Volume of the YEAR-BOOK OF STATE MEDICINE, in which will be embodied the matter of the Sanitary Review, with a complete report of the progress of Forensic Medicine and Toxicology.

The Work, under its new title and publication, will continue to be conducted by Dr. RICHARDSON as principal Editor.

New Burlington-street.

Just published, price 5s.

The Causation and Prevention of DISEASE: showing the innocuousness of putrid exhalations, and pointing out what are the real and efficient causes of disease.

By JOHN PARKIN, M.D.

John Churchill, New Burlington-street.

Just published, in One Vol. 8vo, price 7s. 6d.

A Treatise on Medical Electricity.

By J. ALTHAUS, M.D.

"There existed a hiatus in British Medical literature on the subject which the present work most worthily fills up. Dr. Althaus' Treatise is complete, accurate, and scientific. The book is written in a clear and even elegant style. Dr. Althaus does not address us with the enthusiasm of a specialist, but with the honest conviction of a man of science; hence we feel sure that his book will prove acceptable to the Profession, and will serve to diminish the ignorance which prevails upon the employment of electricity in medicine, while it will materially assist in establishing the claims of this agent upon our serious attention."—British and Foreign Med.-Chir. Review.

"Dr. Althaus has supplied to the English Profession by far the most elaborate and useful book on the subject upon which it treats extant in our mother tongue. The book will command general reference. We expect to see it for some time to come the standard English work on Medical Electricity."—Medical Times and Gazette.

London: Trübner and Co. 60, Paternoster-row.

Just published, fcap. cloth, price 7s. 6d.

Brierre de Boismont on Hallucinations.

A History and Explanation of Apparitions, Visions, Dreams, Ecstasy, Magnetism, and Somnambulism. Translated from the French by ROBERT T. HULME, F.L.S., M.R.C.S.

London: Henry Renshaw, 356, Strand.

Vol. XL. No. 1037.—NEW SERIES, No. 476.

Now ready, with Eleven Lithographic Plates, 8vo, cloth, 12s.

Notes on the Wounded from the

MUTINY IN INDIA: with a Description of the Preparations of Gunshot Injuries contained in the Museum at Fort Pitt. By GEORGE WILLIAMSON, M.D., Staff Surgeon.

John Churchill, New Burlington-street.

Post 8vo, cloth, 10s. 6d.

Digestion and its Derangements.

By THOS. K. CHAMBERS, M.D., Physician to St. Mary's Hospital, and Lecturer on Medicine at St. Mary's Medical School.

There is common sense and sound philosophy in the views taken by Dr. Chambers."—Medical Times and Gazette.

"It is a book which we would, with a good conscience, recommend to a brother practitioner, or place in the hands of a pupil."—Association Medical Journal.

"This is no common publication, to be taken up and thrown aside, but the result of deep study and patient investigation. No person can rise from the perusal of this scientific work without a feeling of deep and deserved respect for the accomplished author."—Dublin Quarterly Journal.

John Churchill, New Burlington-street.

One Vol. 8vo. cloth lettered, price 8s. 6d.

On the Constitutional Treatment of

FEMALE DISEASES. By EDWARD RIGBY, M.D., etc.

"We know of no other obstetric writer who so strongly insists on the intimate connexion between uterine and constitutional disorders, or who has carried out this principle so consistently and so successfully. On this account we look upon the work as peculiarly valuable, and calculated to do an immensity of good at the present time, by dispelling the one-sided and narrow views so generally prevalent respecting this class of diseases, and placing their pathology and treatment on a sounder and more rational basis."—Dublin Quarterly Journal of Medical Science.

London: Renshaw, 356, Strand.

NEW EDITION OF SKEY'S OPERATIVE SURGERY.

In crown 8vo, with many Woodcuts, price 12s. 6d. cloth,

The Principles and Practice of

OPERATIVE SURGERY. By FREDERIC C. SKEY, F.R.S., Member of the Council of the Court of Examiners of the Royal College of Surgeons of England, Surgeon to St. Bartholomew's Hospital, &c. &c. Second Edition, revised and enlarged.

"We accept it as the candid record of the experience of one of the foremost amongst us—as the work of a man who has thought deeply and independently, and has honestly endeavoured to make the knife—what, indeed, it ever should be—the last resource of the Surgeon."—The Lancet.

"The independence of thought and research which characterises it gives it a peculiar merit, and justifies our recommending it to every earnest student of his profession."—British and Foreign Medical Review.

"There is much sound and wholesome doctrine in Mr. Skey's work—his reputation as a good Surgeon cannot fail to be advanced by it."—Medical Times and Gazette.

"We are glad to see this Second Edition, and can honestly recommend it as an invaluable guide to operative practice."—Medical Circular.

London: Longmans, Brown, Green, and Longman.

Just published, 8vo, price 2s.

On the Treatment of the Epidemic

Cholera: a Memoir read before the Members of the French Academy of Sciences, with their Report thereon. By JOSEPH AYRE, M.D. many years Physician to the General Hospital, Hull.
John Churchill, New Burlington-street.

Now ready, price 7s.,

Dedicated by permission to the Right Hon. the Earl of Shaftesbury,

On the State of Lunacy and the Legal

PROVISION for the INSANE; with Observations on the Construction and Organisation of Asylums. By J. T. ARLIDGE, M.B., A.B., L.R.C.P. (Lond.), formerly Medical Superintendent of St. Luke's Hospital.
John Churchill, New Burlington-street.

On Poverty of the Blood, and its SYMPATHETIC DISORDERS.

London: Whittaker & Co.

The Harrogate Spas. 4th Edition.

By Dr. PIGGOTT (Harrogate).
John Churchill, New Burlington-street.

Just published, price 6s. 6d. in cloth, postage 4d.

Meade's Manual for Examination at

Apothecaries'-hall and other Medical Institutions. Third Edition, much improved, and corrected to the present time. Or sold separately.

Part 1.—For the First Examination, price 4s.

Part 2.—For the Second Examination, price 2s. 6d.

London: Henry Renshaw, 356, Strand.

Recreative Science.—The First

NUMBER, price Eightpence, contains:—The Endeavour—Science and the Boy—The Planets, by E. J. Lowe—How to Gather Diatoms, by Tuffen West—Wayside Weeds and their Teachings, by Spencer Thomson, M.D.—Tame Fishes—Humboldt, by Hain Friswell—Water Glass in Photography, by T. A. Malone—Night Flying Moths, by H. Noel Humphreys—Science on the Sea-shore; Flints and Sponges, by Shirley Hibberd—The Key to a Bird's Heart, by William Kidd, of Hammersmith—The Gyroscope, by E. G. Wood—Astronomical Observations for August—Things of the Season—Meteorology for August—Mr. Noteworthy's Corner: How to observe the Habits of Birds—Miniature Rockwork—Flints in the Drift—New Solvent and Cement.

London: Groombridge and Sons, 5, Paternoster-row.

NEW WORK ON POPULAR ASTRONOMY.

On Friday next will be published, in 16mo, illustrated with Woodcuts and a Map of the Moon, 12 inches in diameter, engraved on steel,

Celestial Objects for Common

TELESCOPES. By the Rev. T. W. WEBB, M.A., F.R.S., Incumbent of Hardwick, Herefordshire.

London: Longman, Green, Longman, and Roberts.

Just Published, Price 3s. 6d., with 200 Descriptive Cases, and Illustrations in Chromo-Lithography,

Amputations and Artificial Legs,

HANDS, etc. By W. R. GROSSMITH, of 175, Fleet-street, London.
"Mr. Grossmith has offered some good practical suggestions for the consideration of the operator, and has entered more fully into the subject than has hitherto been attempted."—The Lancet, Nov. 14th, 1857.

"Mr. Grossmith's artificial limbs are well constructed, and on the best system."—Paris Exposition Jury Reports.

London: Longman and Co. Dublin: Fannin and Co.; and from the Author post free.

DR. LITTLE ON DEFORMITIES.

In 8vo, with 160 Engravings and Diagrams, 15s. cloth,

On the Nature and Treatment of

CONTRACTIONS and DEFORMITIES. By W. J. LITTLE, M.D. Senior Physician to the London Hospital, Founder of the Royal Orthopædic Hospital, &c.

CONTENTS.

1. Deformities in general. Treatment Operative, Instrumental, and Physiological. Forcible Extension under Chloroform.
2. Contractions from Wounds and Diseases of Joints, Accidents, Rheumatism, &c.
3. Contractions from Spasm, Paralysis, Burns, Habitual Retention in one Position.
4. Deformities from Rickets, Weakness, and Curvatures of Bones.
5. Congenital Distortions and Dislocations, Club-foot, Club-hand, &c.
6. Congenital Malformations, Monstrosities.
7. Distortions of the Spine, from Strumous Disease, Rickets, Lateral Curvature, Spasm, and Paralysis.

Appendix: On Relapsed and Neglected Cases. Index.

"The best treatise on the subject in any language."—The Lancet, the British and Foreign Medico-Chirurgical Review, and the Philadelphia Medical Examiner.

On CLUB-FOOT and ANALOGOUS DISTORTIONS, including their Treatment both with and without Surgical Operation. 8vo. Forty-one Engravings. 12s.

On ANCHYLOSIS or STIFF JOINT: a Practical Treatise on the Contractions and Deformities resulting from Diseases of the Joints. 8vo. Thirty-two Engravings. 7s. 6d.

London: Longman, Brown, Green, and Longmans.

Now ready, price 5s. 6d., or free by post to any part of the United Kingdom, price 6s., Fourth Edition, greatly enlarged and improved.

A Grammatical Introduction to the LONDON PHARMACOPOEIA, and a KEY to PHYSICIANS' PRESCRIPTIONS. By F. S. LEACH.

"This little work will be found extremely useful to students who have received but an imperfect classical education."—The Lancet.

Hughes and Butler, Medical Booksellers and Publishers, 15, St. Martin's-le-Grand.

South African Sherry, 19s. 6d. Port,

22s. Claret, 18s. Madeira, 24s. Amontillado, 26s. Cognac, 18s. 6d. Her Majesty's Wine Merchant. Specially appointed since May, 1840. JAMES MARKWELL, Cellars, 35 to 40 & 45, Albemarle-street—Offices, 40, Albemarle and 4, Stafford Streets. Ports, from 30s.; Sherries, 30s.; Madeira, 42s.; Hocks, 40s.; Moselles, 40s.; Sparkling Hocks and Moselles, 48s.; Ditto, St. Peray, 54s.; Ditto, Burgundy, 60s.; Clarets, 28s.; Chablis, 38s.; Cote Rotie, 48s.; Champagne, 44s.; Sauterne, 40s.; Ditto, Yquem, 80s.; Essence of Turtle Punch, 56s.; Old Tom, 11s. 6d. All kinds of Foreign Spirits and Liqueurs. Particular and direct Shipments of Montilla, Vino di Pasto, Amontillado, Oloroso, Xres Viejo, Manzanilla, Longworth's Sparkling and Dry Catawba American Peach Brandy; Monongahela and Bourbon Whisky; and Sole Agent for the Celebrated Yankee Bitters. Bottled Stock for inspection, 6000 dozen. Cash or Reference. As usual, very liberal prices given for genuine Old Bottled Wines. Half-pints of first-class Champagne only.

N.B.—A considerable quantity of the Old Bottled Wines removed to Mr. M.'s Stock from Long's Hotel, North and South American Coffee House, Shugborough Park, and the celebrated Reading Sale.

For Infants.—The British Feeding

BOTTLE (registered) may be placed in any position without the Food running out. The supply can be regulated by a stop-cock; being electroplated, it may be instantaneously cleaned. Unlike wood, ivory, or bone, it is impervious to moisture, cannot crack or become sour; there is no possibility of the infant drawing air with the food.

By W. T. COOPER, Pharmaceutical Chemist, 26, Oxford-street, London.

Price 7s. 6d., or free to any Railway Station, 8s. 6d.

IMPORTANT TO THE PROFESSION.

Blancard's Pills of Unchangeable

IODIDE OF IRON,

Recommended by the Academy of Medicine of Paris, and authorised by the Medical Council of St. Petersburg, Extensively tried in the Hospitals of France, Belgium, Ireland, Turkey, &c. Favourably noticed at the Universal Exhibition of New York, 1853, and Paris, 1855.

"Of all the modes hitherto proposed of administering iodide of iron in the pure state, I think Mr. Blancard's the best."—Chemistry applied to Therapeutics, by M. Mialhe, Deputy-Professor to the Faculty of Medicine of Paris, Pharmacien to the Emperor, 1856, p. 319.

These Pills stand now very high in the therapeutics of every country, as may be seen by the above quotations, and also by the numerous scientific articles in medical periodicals and works (a).

Being enveloped in a very thin resino-balsamic coating, they present the great advantage of not being liable to any deterioration, of having no taste, of being small, and not distressing the stomach. As they possess the properties both of iodine and iron, they are especially beneficial in chlorotic, scrofulous, tubercular, or cancerous affections, as also in leucorrhœa, amenorrhœa, anæmia, &c. &c., and they furnish the medical man with an excellent means of modifying lymphatic, feeble, and debilitated constitutions. Dose, 2 to 4 pills a day.

N.B.—Impure or altered Iodide of Iron is an unsafe remedy, and may even prove dangerous. Only such bottles as bear an electro-plated seal fixed to the lower part of the cork, and the signature of the inventor placed on a green label, are to be considered as prepared by Mr. Blancard. The public should beware of spurious imitations.

To be had at M. BLANCARD'S, Pharmacien, Rue Bonaparte, No. 40, Paris. General dépôt in England at M. Gabriel Jozeau's, French chemist, 49, Haymarket, London. In Ireland, at Mr. Vitties, Stevens's Hospital, Dublin. In the United States, at E. and S. Fougere, Chemists, 30, North William-street, New York. To be obtained retail from the principal Chemists.

(a) Bulletin de l'Académie de Med 1850, page 1015; Gazette Médicale, Aug. 17, 1850; Union Médicale, Aug. 15 and 22, 1850; Gazette des Hôpitaux, March 15, 1853, and June 10, 1854; Gazette Hebdomadaire de Médecine et de Chirurgie, Aug. 31, 1855; Revue de Thérapeutique Médico-Chirurgicale, Feb. 15, 1855; Abeille Médicale, Revue Clinique; Répertoire de Chimie et de Pharmacie; Annuaire de Thérapeutique pour 1851, page 199; Orfila, Elements of Chemistry; Mialhe, Chemistry applied to Therapeutics, 1856, p. 319; Quevenne, Essay on the Physiological and Therapeutical Action of Preparations of Steel, page 97, 1854; Bricheateau, Treatise on Chronic Diseases seated in the Respiratory Organs; Soubeiran, Treatise on Pharmacy; Dervault, Officine, &c. &c.

Wines from the Cape of Good Hope.

W. and A. GILBEY'S SOUTH AFRICAN PORT, SHERRY, &c. &c., 20s. per Dozen. First growths only. Two samples for 12 stamps. Wine Importers and Distillers, 357, Oxford-street, London (W.); 31, Upper Sackville-street, Dublin; and 12, St. Andrew-square, Edinburgh. Medical Reports, Price Lists, &c. sent post free.

NO LIVE STOCK ON BOARD SHIP.

Joints of Beef and Mutton, also Poultry,

are now Preserved by HAND'S PATENT. That they will keep quite fresh in an uncooked state in all climates, and when eaten cannot be known from fresh-killed food, cooked meat need not now be taken.

For prices or samples apply to Mr. HESKETH S. DAVIS, 24, Leadenhall-street, London, E.C.

POULTICES SUPERSEDED! SPONGIO PILINE.

The Profession are respectfully

informed, that the WANDLE FELT COMPANY having purchased Mr. MARKWICK'S PATENT for the well-known SPONGIO PILINE, for the application of moist heat, in lieu of Poultices and Fomentations, and the IMPERMEABLE PILINE, for Rheumatism, for promoting perspiration, and for the application of stimulating liniments, are now supplying these articles, of superior manufacture, and at greatly reduced prices, at 27, BEDFORD-BURY, COVENT-GARDEN, London, and also through the Wholesale and Retail Druggists in town and country.

Pepsine.—M. Boudault begs to state

that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, her Majesty's Chemist, 277, Oxford-street, London, to whom all applications respecting it must be addressed.

Second Edition of Boudault on "Pepsine," with Remarks by English Physicians. Edited by W. S. SQUIRE, Ph. D., published by J. Churchill, London, may be also had of the Author, 277, Oxford-street, price Sixpence.

Great Saving in the Purchase of New

Williams and Son's Pure Glycerine

SOAP. Analysed by Dr. Hofmann, F.R.S., and Professor Redwood, Ph.D., strongly recommended by many eminent members of the Medical Profession, and favourably noticed by the following Medical Journals:—

THE LANCET.
THE MEDICAL TIMES AND GAZETTE.
THE BRITISH MEDICAL JOURNAL.
THE MEDICAL CIRCULAR.
EDINBURGH MEDICAL JOURNAL.
THE DUBLIN HOSPITAL GAZETTE.

It is suited to all cases of delicate skin (whether arising from disease or otherwise), and is admirably adapted for nursery use. May be had of all respectable Chemists, Perfumers, &c.

SOAP-WORKS, CLERKENWELL, LONDON, E.C.

Struve's Seltzer, Marienbad, Vichy,

KISSINGEN, and other MINERAL WATERS.—Under her Majesty's especial Patronage.—ROYAL GERMAN SPA, BRIGHTON, STRUVE'S PUMP-ROOM and PROMENADES, offering every facility for a Course of Mineral Waters, as perfect and beneficial as at the natural springs, are NOW OPEN, for the Thirty-fifth Season. A prospectus, with the highest Medical testimonials, may be obtained gratis, at the Pump-room, or from George Waugh and Co. Chemists to the Queen, 177, Regent-street (westside), London, and other respectable houses in London and the provincial towns, where orders for Struve's Bottled Mineral Waters continue to be executed.

CAUTION.—The success obtained by Struve's Mineral Waters, owing to their perfect identity with those of the natural springs, has induced several parties to attempt imitations, sold as "Brighton Seltzer," "Brighton Vichy," &c., an analysis of some of which has shown an utter disregard of their true chemical composition. To distinguish Struve's Waters from all others, every bottle has a label and red ink stamp over the cork, each bearing Struve's name, without which name none is genuine, though contained in Struve's old bottles.

Best Iron Wire, prepared expressly by

COCKER BROTHERS, NURSERY-STREET, SHEFFIELD, for SURGICAL PURPOSES, as supplied to Professor Simpson, Edinburgh; Dr. Churchill, Dublin; Mr. T. Spencer Wells, London; Dr. Bozeman, Montgomery, U.S.; and many others.—See Professor Simpson's Lecture in Medical Times, January 1st, 1859.

Carriages, New and Second-hand, of

superior style, sterling quality, and finest finish at reasonable rates, for cash, credit, job, or exchange. Circular of prices on application. Credit given when required. Buyers should take carriages on trial, with power to purchase by yearly payments, and thus prove them.

OFFORD'S PATENT MEDICAL MAN'S BROUGHAM MANUFACTORY, 79, WELLS-STREET, OXFORD-STREET.

Superphosphate of Iron and Super-

PHOSPHATE OF IRON and LIME. New Remedial Agents introduced to the notice of the Profession at the Meetings of the Medical Society of London, and now extensively employed by the most eminent members of the Medical Profession. The Syrup is the most eligible mode of administering these valuable Remedial Agents. Mr. GREENISH will be happy to forward a variety of cases which have been furnished to him, where its success has been most marked, and which will serve to indicate where it may be most advantageously employed.—20, New-street, Dorset-square.

Varicose Veins and Supporting Bands.

—SURGICAL ELASTIC STOCKINGS AND KNEE CAPS, previous, light in texture, and inexpensive, yielding an efficient and unvarying support, without the trouble of lacing. Likewise, a strong low-priced article for Hospitals and the Working-Classes. ABDOMINAL SUPPORTING BANDS for both Sexes; those for Ladies' use, before and after accouchement, are admirably adapted for giving adequate support with extreme lightness—a point little attended to in the comparatively clumsy contrivances and fabrics hitherto employed. Instruction for measurement and prices on application, and the articles sent by post from the Manufacturers and Inventors, POPE and PLANTE, 4, Waterloo-place, Pall-mall, London, S.W.

The Profession, Trade, and Hospitals, supplied.

Crosse and Blackwell, Purveyors in

Ordinary to Her Majesty, respectfully invite attention to their PICKLES, Sauces, Tart Fruits, and other table delicacies, the whole of which are prepared with the most scrupulous attention to wholesomeness and purity. The practice of colouring pickles and tart-fruits by artificial means has been discontinued, and the whole of their manufactures are so prepared that they are not allowed to come in contact with any deleterious ingredient. A few of the articles most highly recommended are, Pickles and Tart Fruits of every description, Royal Table Sauce, Essence of Shrimps, Soho Sauce, Essence of Anchovies, Jams, Jellies, Orange Marmalade, Anchovy and Bloaters Pastes, Strasbourg and other Potted Meats, and Calf's-Foot Jellies of various kinds for table use. C. and B. are also sole agents for M. Sayer's Sauces, Relish, and Aromatic Mustard; and for Carstairs' Sir Robert Peel's Sauce, and Farnes' Royal Osborne Sauce. The above may be obtained of most respectable Sauce Vendors throughout the United Kingdom; and Wholesale of

CROSSE and BLACKWELL, 21, Soho-square.

Or SACCHARATED CAPSULES.—Copaiba and Cubebs are, doubtless the best remedies, but these drugs are of a repulsive taste and odour, and occasion colicky pains, nausea, and gastric disturbance. M. Jozeau has succeeded in rendering these valuable therapeutic agents perfectly innocuous, by increasing, in his Copahine, all the curative properties. This preparation has been adopted by the Paris Academy of Medicine, after more than a thousand trials in Paris, and the different London Hospitals, viz., St. Thomas's, Guy's, and St. Bartholomew's, under the care of Messrs. Lloyd, Poland, and Legros Clark. "Lancet," Nov. 6, and Dec. 10, 1852. The Copahine, which is in form of a pretty pink sugar-plum, effects a cure in about six days, either in recent or chronic diseases. 100 Capsules, 4s. 6d.: at G. JOZEAU'S, French Chemist, 49, Haymarket, London; 22, Rue St. Quentin, Paris; and all the most important Chemists.

Pillischer's Achromatic Microscopes.—

To meet the daily increasing demand for his Microscopes, M. PILLISCHER has recently completed extensive alterations in his workshops to enable him to manufacture MICROSCOPES and their Object Glasses upon a more expeditious and extensive scale. M. P. has the pleasure of informing the Profession that he is now able to furnish Microscopes of the very greatest perfection; possessing every modern improvement; and with Object Glasses of a quality unsurpassed by any other maker, on the shortest notice, and at very moderate prices.

PILLISCHER'S £7 7s. STUDENTS' MICROSCOPE, for which a prize Medal was awarded to him at Paris Exhibition, 1855, deserves particular notice. It consists of a well-constructed Stand, with coarse and fine adjustments, a capital Stage, with Diaphragm and Large Mirror, one Eye-glass, one and one quarter inch Object Glasses, 16° and 75° angular aperture, and a neat Mahogany Case about 7 in. square. The above Microscope when further completed with the addition of a Second Eye-glass, Condenser for Opaque Objects, Live Box, Stage Forceps, Large Glass Stage, and Polarising Apparatus, price £10, forms a most complete and valuable Microscope, and in every respect as useful as a much more expensive one.

A Catalogue post free on application to M. Pillischer, Optician, 88, New Bond-street, London, W.

The objects of this Association are to secure correct Registration, to prevent Illegal Practice, and to watch the working of the new Medical Act. All Practitioners of orthodox Medicine entitled to be registered under the new Medical Act are eligible as Members. The minimum subscription is 5s. annually, but Members are earnestly invited to subscribe more liberally, and also to subscribe to the Prosecution Fund, to enable the Association fully to carry out its objects. Subscriptions are received by Dr. THEODORE EDWARD LADD, Honorary Secretary, 5, Charing-cross, London. Post-office orders to be made payable at Charing-cross Post-office.

WATER BEDS.—EDMISTON and SON, 5, Charing-Cross, beg to call

the particular attention of the Managers of Hospitals and Dispensaries, and the Medical Profession generally, to the prices and quality of their Hot or Cold Water Beds. The prices hitherto charged being so high as to limit the sale of such articles to the affluent, they are induced to offer them at such prices as will enable the public generally to realise the advantage and comfort to be derived from their use.

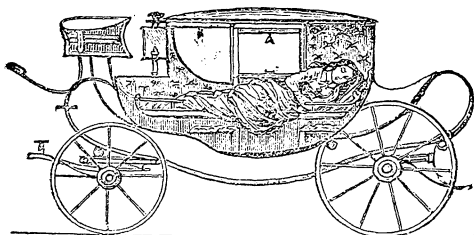

WATER BEDS, £3 13s. 6d., £5 5s., and £3 16s. 6d.

Water Pillows and Cushions, 7s. 6d. to 21s. Urinals, from 3s. 6d. to 12s. 6d. Cotton Elastic Stockings, 4s. 3d. Silk, 5s. 3d. Knee Caps, Leggings, Anklelets, &c.

BED SHEETS, ACCOUCHEMENT BELTS, &c. India-Rubber Chamber Utensils for Lunatic Asylums, 7s. 6d. each, or 75s. per dozen.

WATER BEDS ON HIRE. TERMS, 7s. 6d. PER WEEK.

LONDON: EDMISTON AND SON, 5, CHARING-CROSS, LATE 69, STRAND.

IMPROVED INVALID COT CARRIAGES,

THE GREATEST LUXURY AND COMFORT EVER INTRODUCED FOR REMOVING INVALIDS, BEING FITTED UP WITH THE PATENT NOISELESS WHEELS.

These Carriages may be engaged, on moderate terms, for any journey, on application to

H. & J. READING,

COACHBUILDERS, 14, RIDING-HOUSE-STREET, CAVENTISH-SQUARE.

Also a good assortment of New and Second-hand Broughams and other Carriages for Sale or Hire.

Scammony Manufactured from the

ROOT.—This Pure Resin may be had of all Wholesale Druggists at 8s. per lb.

The Medicinal value of this Scammony was fully explained at a meeting of the Pharmaceutical Society, and reported at length in their journal of March last, from which the following are extracts:—

"From these numerous observations, one hundred and twenty in number, together with many others which have not been tabulated, I am quite convinced that the scammony prepared by the new process from the untapped root is quite equal, as a remedy, to the very best virgin scammony which is met with in commerce, and equal, in fact, to the resin which is extracted from commercial scammony by means of ether; and it possesses this most important advantage over the scammony of commerce, namely, of being entirely free from the frauds which are almost constantly practised upon it in the country where the plant grows, and in which it has hitherto been collected, and, therefore, being perfectly uniform in its physical characters, composition and therapeutic action. There can, therefore, be no objection, but, on the other hand, manifest advantage, in employing it in place of the scammony commonly met with."

"A. B. GARROD, M.D., F.R.S., F.R.C.P."

"Professor of Materia Medica, Therapeutics and Clinical Medicine at University College; Physician to University College Hospital."

"I have endeavoured to ascertain the relative activity of Messrs. M'Andrew's scammony, and of a fine specimen of commercial virgin scammony, by prescribing these drugs alternately in equal doses to the same patient. The results, according to the judgment of myself and others who have assisted me in watching the cases, is that in most instances Messrs. M'Andrew's scammony has proved itself decidedly more active than the virgin scammony. As to pleasantness of operation, or the reverse, there seemed to be no choice between the two specimens."

"That a preparation of scammony should be a little more or a little less active is of comparatively small importance. It is far more important that the drug should have a fixed and uniform composition and activity, so that the prescriber may know, with an approach to certainty, what doses are required to produce a given effect. This advantage of uniform activity Messrs. M'Andrew's scammony seems likely to possess over the scammony which has hitherto been in common use, and which is a drug notoriously of most uncertain composition and power."

"GEORGE JOHNSON, M.D., F.R.C.P."

"Professor of Materia Medica and Therapeutics in King's College; Physician to King's College Hospital."

CLINICAL LECTURES

ON

THE DISEASES OF WOMEN.

By J. Y. SIMPSON, M.D. F.R.S.E.

Professor of Medicine and Midwifery in the University of Edinburgh.

LECTURE XX.

PERI-UTERINE OR PELVIC HÆMATOMA, AND VARIX OF THE PUDENDAL VEINS.

GENTLEMEN,—In my last two lectures I have been directing your attention to inflammation of, and inflammatory effusions into, the cellular tissue of the pelvis. To-day it is my object to describe the

HISTORY OF HÆMATOMA OF THE PELVIS;

another disease to which the cellular tissue of the pelvis is liable, and this affection, though still less known than pelvic cellulitis, because less frequent, is well worthy of your most careful study, for this reason, if for no other, that it is relatively more fatal than pelvic cellular inflammation. In the affection, too, which I am to speak of in the present lecture, there is an effusion into the tissue filling up the angles and spaces between the layers of the pelvic fascia; but here the effusion consists, not of serum or other inflammatory products, but of blood from a ruptured blood-vessel. This pelvic hæmatoma or pelvic hæmatocele is, as I have observed, far from being as common as pelvic cellulitis; but it is not by any means such a rare disease as you might be led to suppose from finding that there is almost no notice taken of its occurrence in the whole wide range of modern English obstetric literature; and I feel assured that if any of you in after years have occasion to see much of female diseases, you will not have been very long in practice ere you meet with one or more examples of this affection.

The first case of pelvic hæmatoma where I recognised the real nature of the disease, occurred, many years ago now, in the person of a patient whom I saw in consultation with my friend, Dr. Baird, of Linlithgow. The lady was exposed to cold by sitting on the grass when she was menstruating: she had a fit of shivering on going home which lasted some time, and was succeeded by sudden and severe pain in the region of the womb. Some days subsequently, on making a vaginal examination, a solid-like tumour was felt behind the uterus, stretching upwards towards the cavity of the abdomen. I thought it was a case of acute pelvic cellulitis, and it was treated as such for a time by means of antiphlogistics. Between two and three weeks having elapsed, and the tumour not having become diminished in size, I believed that it was time to puncture it, imagining that suppuration must have taken place, though perhaps so deeply seated as not to give rise to a distinct feeling of fluctuation. I therefore made an incision into the tumour through the roof of the vagina, but, instead of pus, there came out masses of old coagulated blood, partially broken down and disintegrated. There was, indeed, a slight admixture of purulent fluid, for inflammation had occurred secondarily around the infiltrated part; but the great bulk of the evacuated matter consisted of the *débris* of blood-clots; and after these had all been evacuated, the cavity speedily closed up, and the patient made a good recovery.

I did not then properly understand all the phenomena of the case, and thought it to be simply an aberrant form of pelvic cellulitis; but since I saw that case I have met with a considerable number of others, and I have now no doubt that it is an altogether independent form of disease. We had a fatal case of it in the Hospital five years ago; and as this case is a very instructive one, perhaps you will allow me to read you the history of it, which has been preserved in the Hospital records. I regret that this history is so imperfect, and especially in relation to the post-mortem appearances, as taken down by the clinical clerk.

"A. W., aged 42, married. Admitted April 9th, 1854. Has generally menstruated two days every month since the first commencement of the catamenia in adolescence. The dis-

VOL. XL. No. 1037.—NEW SERIES, No. 476.

charge was never in large quantity, and was generally untended with pain. Gave birth to a child four and a-half years ago, and for four years she has suffered from prolapsus uteri and profuse leucorrhœa. During the first two years she used to keep the uterus reduced by wearing a globular wooden pessary, but during the last two years she has used nothing at all, the womb usually being prolapsed most of the day, and she reduces it herself on going to bed. She never had real pain during menstruation until the last period, which was protracted four or five days longer than usual. The pain then felt was deeply-seated in the lower part of the abdomen, and was so severe as to confine her almost constantly to bed. On the day after the menstrual discharge ceased she felt cold, and in the evening shivered a little; but no feverish symptoms followed, and it was only the continuance of the acute pelvic pain that caused her to seek admission. Since the commencement of the pain the uterus has not appeared in its usual prolapsed form externally. The patient is pale and spiritless, has a cool moist skin, a slightly furred tongue, no great appetite, and no thirst. Pulse 80, soft. Complaints of pain deep in the pelvis, but states that it is not nearly so severe as it had been for three days before; no pain in thighs or back.

"On vaginal examination, a globular swelling is met with in the posterior wall of the vagina, not very tender, nor pitting upon pressure. The cervix uteri is very small, and lies immediately behind the symphysis pubis. The os is small, and the lips are very small and œdematous. The uterus feels fixed by this tumour, which extends from the posterior part of it down to within an inch and a-half of the vaginal orifice. The finger can be easily pushed upwards on each side of it in the direction of the broad ligaments, so that by this means it can be readily ascertained that this swelling has no lateral attachments to the sides of the pelvis, but is merely situated between the rectum and the vagina. This latter point is confirmed by recto-vaginal examination made by the fore and middle fingers of the right hand, for by this means the lower segment of the tumour is embraced between the two fingers. There is no fulness in either iliac region. Urine of sp. gr. 1012, alkaline; contains triple phosphates, and much albumen. To have five-grain doses of bromide of potassium thrice a day.

"April 12.—To stop bromide. \mathcal{R} Infus. gentianæ \mathfrak{z} viij., tinct. gentian. \mathfrak{z} j., corrosiv. sublim. gr. $\frac{1}{4}$. M. Sumat \mathfrak{z} j. ter in dies.

"15th.—Gums are red, tender, and a little spongy; breath fetid; slight salivation. Omit medicine. To have a gallic acid gargle.

"21st.—The œdematous state of the vaginal tumour has now gone, but the tumour has not decreased in size. Dr. Simpson introduced an exploring needle into the tumour, and on withdrawing the canula found it filled with a bloody-looking matter with minute clots of blood. On microscopical examination this fluid was found to consist of a dark brown fluid containing a very few blood discs in various stages of disintegration, and also about an equal number of hyaline or pyoid bodies, but no pus globules. To have five-grain doses of bromide of potassium.

"26th.—Yesternight she had a slight attack of tympanitis without tenderness, and of vomiting. Hot turpentine fomentations, a turpentine enema, and an opiate by the mouth relieved these symptoms, and the patient slept well. To-day the sickness and vomiting have returned with great severity, so that the little fluid aliment which the patient occasionally takes is almost immediately vomited. Tongue covered in the centre with a brown fur; margins clean and moderately moist. Skin warm and moist. There is no abdominal tenderness, and patient feels only a dull uneasiness in the region of the pelvis. Vagina is hot; no increase in size of tumour, but it is softer than before, and yields an indistinct feeling of fluctuation. Pulse 90. Twelve leeches to be applied over the abdomen; and a grain of opium to be taken every five hours.

"27th.—Vomiting almost incessantly. Had about three hours' sleep during the night. To have ice and brandy, with hydrocyanic acid mixture, and a blister to the abdomen. Vespere.—Unabated retching and vomiting; vomited matter contains a good deal of bile; pulse 96. Vagina is tender, and so hot that it is painful to retain the finger a few seconds. Fluctuation much more distinct in tumour. Apply eight leeches round the anus, and continue the treatment pursued in the morning.

"28th.—Retching less, but still severe. Skin keeps cool and moist; pulse 90; tongue not much furred. There was drawn

off from the vaginal tumour by means of a trocar and canula five and a half ounces of a dark-brown fluid, containing a very few minute clots of blood, and patches of lymph or pus. Its odour was very fetid. On microscopical examination it is found to contain pus globules in large quantity, puckered and irregular blood globules, granular matter, and small masses of aggregated particles, sometimes of a semi-crystalline form, and of a deep red colour (Hæmatin?). Stop all medicine, and use ice and brandy.

"29th.—More fluid being still in the tumour, an incision about an inch in length was made into it at its lower part, on the right side of the vagina, and about two inches from its orifice. Four and a-half ounces similar to that drawn off yesterday came away at the time, and about two ounces more escaped during the day mixed with a few clots.

"30th.—Pulse 86. A good deal of fetid fluid comes away from the vagina. Still vomiting and retching every hour or so. Neither medicine nor food remain on the stomach above a few minutes.

"May 1.—Expression of face very much altered and pinched. Tongue dry and brown; vomited matters quite bilious; bowels opened to-day. To have injections of nutritive soups. Pulse 80.

"2nd.—Face more sunk and pinched than yesterday. Pulse 70. Vomiting and retching more urgent. Vaginal discharge diminished. Still using vaginal injections of tepid water, rectal injections of soups. Takes brandy by the mouth, but generally vomits it.

"3rd.—Pulse 40. Retching and vomiting still. Vaginal injections of tepid water came away almost colourless.

"4th.—Gradually sunk and died at 4 a.m.

"Autopsy, made thirty hours after death.—Great rigor mortis. The thoracic organs quite natural. The inferior extremity of the great omentum was found to be adherent to the upper and back part of the uterus. On passing the hand down into the pelvis, both the cæcum and rectum were found adherent to the viscera. The whole of the pelvic contents were removed together, when it was found that there was a soft tumour just in front of the right broad ligament. On making an incision into this, some dirty purulent matter escaped; but the rest of the cavity was filled with large, undecolourised, pretty firm clots of blood, and the opening at the bottom of the cavity, made during life, communicated with the upper part of the vagina. The liver was divided into a number of additional lobes by the presence of several deep fissures, and the kidneys were in a state of waxy degeneration."

It so happened that during the same week in which the death of this Hospital patient took place, I had a patient in private practice who died of the same disease. She was sent from a great distance to Edinburgh, in consequence of a pelvic

Fig. 1.

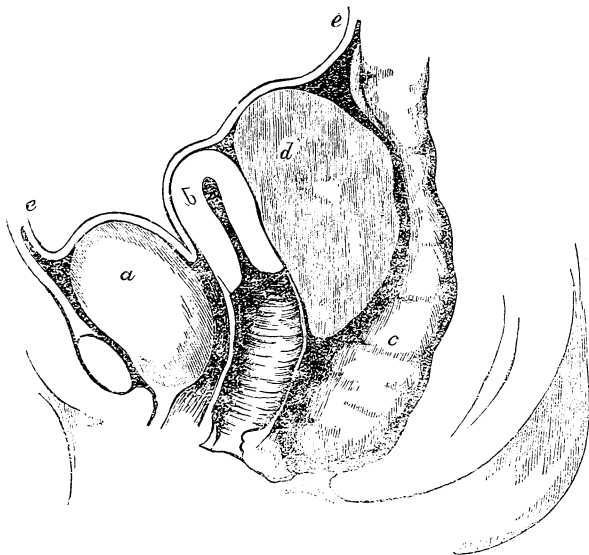

Fig. 1.—Shows the situation of the hæmatoma (d) between the uterus (b) and the rectum (c). (a) The bladder.

tumour having suddenly appeared. Fatal inflammation was set up by the journey. On dissection, I found the reflection of the peritoneum between the uterus and rectum raised up, as shown in this diagram (see fig. 1), and a large mass of broken coagula of blood formed the tumour, having been extravasated behind the peritoneum, forming the posterior covering of the broad ligament, and, as it accumulated, having separated and pushed before it that portion of peritoneum and the utero-rectal fold of this membrane. In the present state of uterine pathology, we can recognise the malady with tolerable certainty, and we all see cases of it ever and anon occurring. Nay more, now that we have a clear conception of the nature of the disease, when we begin to consult the older authors, we find that some of them had tolerably distinct ideas as to its nature, and a positive knowledge of its occurrence. Ruysch more particularly has described some cases of it; and in the obstetrical books that are usually classed with the Hippocratic writings, there are distinct indications that the author had some acquaintance with this affection even at that early period.

NOMENCLATURE OF THE DISEASE.

The disease has received different names from the authors who have written anything regarding it. There are many notices of it in French literature, and by French authors it is generally spoken of as Retro-uterine Hæmatocele. Others call it Peri-metrite and Peri-uterine Hæmatocele, from the fact that it is not confined in position to the cellular tissue lying behind the uterus, although that is its chosen seat. It is spoken of, again, as Pelvic Thrombus by others, because the swelling is of the same nature as the surgical thrombus sometimes seen in the labia pudendi, as a result of injury to some of the vessels there. Here, we have been in the habit of speaking of it as Pelvic Hæmatoma, because that name expresses simply what the disease in reality is, viz., a blood-tumour or effusion in the cellular tissue of the pelvis; and that you may be able to understand its nature, and to recognise the disease when it comes before you in practice, let me proceed to tell you something of the manner in which it seems to be produced, or to tell you, in other words, what is known regarding

THE PATHOLOGICAL ANATOMY AND PATHOLOGY OF THE DISEASE.

It occurs, let me first of all remark, sometimes in puerperal women, but more frequently we meet with it in non-puerperal females, and altogether unconnected with the parturient process. It is seen in patients of all ages; but is more frequent about the age of thirty, according to my experience, than at any other period of life. The disease seems to be usually produced by the rupture of one of the veins or arteries that supply the ovary, and pass to it between the layers of the broad ligament. The blood escaping from the ruptured and sometimes varicose vessel, infiltrates into the cellular tissue of the broad ligament, and those neighbouring parts of the pelvic cellular tissue which communicate freely with it, forming there a swelling or tumour composed of this effused and incarcerated blood, as in a thrombus or blood-swelling of the sub-cutaneous cellular tissue from injury, or as in the so-called sanguineous apoplexy of the brain, lungs, and other organs. As the blood extravasated from the broken utero-ovarian vessel accumulates in the surrounding cellular tissue, it separates the serous layers of the broad ligament from each other, or raises and pushes before it, more particularly, one of these layers, to form, as it were, a covering to the blood-tumour. More especially is the posterior peritoneal layer often apparently separated and displaced in this way, as well as the fold of peritoneum stretching between the uterus and rectum. It is this affection which constitutes the true pelvic or retro-uterine hæmatocele. But, occasionally, there is a form of pelvic hæmatoma of a different origin, and with the effused blood in a different site. For according to the evidence of various French pathologists, as Nelaton, Laugier, and others, a retro-uterine hæmatocele may be formed by blood accumulating *within* the pelvic portion of the peritoneum, the blood collected in this locality having escaped from a ruptured ovarian vesicle during menstruation, from the fimbriated extremity or course of the Fallopian tube, or even from the cavity of the uterus—the blood regurgitating along the Fallopian tube into the peritoneal cavity. Certainly, sometimes, even when the site of the hæmorrhage is a rup-

tured vessel of the ovarian or uterine plexus enclosed within the broad ligament, the effused blood has burst through the opposing layer of peritoneum, and escaped directly into one of the peritoneal pouches behind or in front of the uterus, where its presence has acted as an irritant to the peritoneum, and led to its being encysted and enclosed in a separate cystic cavity, produced by the adhesion of opposed inflamed surfaces. These ruptures of the blood-vessels of the utero-ovarian plexus, and consequent extravasations of blood, most frequently occur during a menstrual period, when a certain degree of excitement and physiological congestion are set up in the ovary, for then the vessels being more distended with blood will be more likely to give way in their coats under the action of any unusual impetus. The blood which escapes from the injured vessel or vessels passes in between the layers of the broad ligament and separates them from each other, forming a tumour in many respects resembling the inflammatory tumour produced by the effusion of serum into the same locality, but only forming more rapidly and suddenly, without any premonitory symptoms. Or, one of the terminal branches of these ovarian vessels may give way, and the blood be thrown into the substance of the ovary itself. This rarely happens in the healthy ovary, but it has now been not unfrequently seen in cases where the organ has been altered and rendered friable as a result of disease; and then the extravasated blood, after breaking up the softened structures of the ovary, may make its way eventually into the cavity of the peritoneum. It would seem, I have said, in some cases as if the rupture occurred in a superficial vessel, and the extravasation took place directly into the peritoneal cavity. A very melancholy and distressing instance of this kind of injury occurred, many years ago, in a patient of Dr. Malcolm, of Perth. This patient, when otherwise apparently in perfect health, was suddenly seized one forenoon with pain in the abdomen, and faintness, which went on increasing during the day, in spite of the most skilful treatment. That same night the lady died, and at the post-mortem examination the abdominal cavity was found filled with coagulated blood which had escaped from a ruptured blood-vessel, lying in the broad ligament of the uterus. Most frequently, as I have stated, extravasations of blood into the cellular tissue of the pelvis result from rupture of one of the ovarian vessels as it courses along the broad ligament, and they usually occur in connexion with menstruation. But it is proper to add that pelvic hæmatomas may have other sources and seats, for other vessels besides the ovarian vessels are liable to rupture. Thus I saw some time ago, along with Dr. Young, a patient in whom one of the upper hæmorrhoidal vessels had given way, and led to the formation of a hæmatoma of large size in front of the rectum, where it could be distinctly felt between that canal and the cavity of the vagina. Tumours of this nature are not unfrequently met with also in the walls or at the sides of the vagina, but rarely of any great size. Indeed, there is almost no limit to the variety of situations in which a pelvic thrombus or hæmatoma may be found, for the veins may give way in any part of the pelvis, and the blood which escapes may fill sometimes one fascial loculation only of the pelvis, and at other times several at once.

You will find that various accounts have been given as to the size of the swelling, and various statements made as to the extent to which hæmorrhage may take place into the loculi of the pelvic fascia. Of course all this varies greatly in different cases and different patients. I have seen two or three instances where a pelvic hæmatoma was as large in size as a gravid uterus in the fourth or fifth month of pregnancy. In practice you will usually find them much smaller, and in most cases you will ascertain their presence by a vaginal rather than an abdominal examination. The most frequent form is where the extravasation occurs between the layers of the broad ligament, where it is confined and limited in size, and rounded and elongated in form; or it may extend from this, separating the layers and passing down among the cellular tissue behind the cervix uteri, or between the rectum and vagina. In this case the tumour, like that formed by the serous effusion of pelvic cellulitis, may be at first small in size and rounded in form, but rapidly, as the extravasation spreads, the tumour becomes enlarged in size, elongated or irregular in shape, and fitting itself to the contour of the cavities into which the blood is thrown.

(To be continued.)

ORIGINAL COMMUNICATIONS.

DISINFECTION OF THE THAMES AND OF THE SEWAGE OF LONDON.

By DR. ALBERT J. BERNAYS,
Lecturer on Chemistry at St. Mary's Hospital.

THE present state of the Thames has become so dangerous to the whole community, that it has at last drawn the attention of the authorities to the consideration of some plan by which probable evil results may be prevented. Hence experiments have been made with various disinfectants at the request of the Metropolitan Board of Works by Professor Dr. Miller, of King's College. What the results are at which he has arrived, I have no exact means of ascertaining; but having for three years made special experiments with different disinfectants upon London sewage and Thames water, and having last year especially drawn the attention of a portion of the scientific public through the medium of your valuable paper, to the effects produced, I shall make no apology for repeating my experience upon Thames sewage in the present year.

It may be well to state that the experience which I gained last year was so entirely in favour of the disinfectant of Messrs. Smith and MacDougall, of Manchester, that I was induced early in the present year to repeat them. I again found that sewage of the worst description, emitting the most deleterious gases, could be rendered perfectly sweet and harmless, emitting only the odour of the impure coal-kreosote (carbolic acid), which forms the important feature of the invention of Dr. R. Angus Smith and Mr. Alexander MacDougall. Whenever a sufficient quantity of the disinfecting powder was employed, I found that sewage precipitated in May was perfectly free from sewage odours in July; and sewage-deposit, which is the worst part of sewage, when similarly dealt with, remains to this day equally beneficially affected. Comparing these results with those I published last year, and especially comparing the disinfected specimens with one which I have had these three years (last June) in my possession, and finding the results perfectly in concordance, it cannot be wondered at, that, with a knowledge of these facts so greatly in their favour, Messrs. Smith and MacDougall should desire me to make notes of my experiments, which might be made under the direction of the Board of Works. Accordingly I have done so to the best of my ability, and with a sincere desire to ascertain the truth. I subjoin such results I have arrived at:—

According, I believe, to Dr. Miller's suggestion, Mr. Mac Dougall employed a portion only of his patent, viz. that which embraces the use of carbolic acid (kreosote) and lime. Although I am of opinion that these include the most valuable portion of the discovery, yet I cannot but think, that the whole patent, which involves the additional employment of sulphites of lime and magnesia, is better suited to effect the object, viz. prevention of the decomposition of animal and vegetable matter. However this may be, the results of the experiment on a large scale carried on in Tavistock-street, Tottenham-court-road sewer, are sufficiently satisfactory to warrant the same application to the Thames.

The quantity of carbolic acid employed in the above sewer averaged 685 lbs. per day, together with 70 lbs. of lime and 12,000 gallons of water. On the hottest days a larger amount appears necessary, as may be judged by the experiments about to be recorded. At least it is certain, that when another hundredweight or so was employed in excess of the above 685 lbs. the sewage bore the highest temperature to which it could be exposed under the highest conceivable solar influences, without evolution either of sulphuretted hydrogen or any other foul emanation.

The clear amber-coloured solution of carbolate of lime was churned into the sewer. The experiments were commenced by me on July 13, the specimens being the precise counterparts of those furnished to Professor Miller.

The results were as follows:—

Sample B. July 13.—Taken from Tottenham court-road, above the opening where the disinfection commenced. The sewage was very dark in colour, nearly black. The smell

attached chiefly to the deposit, which, when mixed with the water, diffused an indescribable loathsomeness. It was not so much of sulphuretted hydrogen, although lead-paper was browned in the course of an hour, proving the evolution of at least one gas dangerous to health. The water, after free exposure in suitable vessels to the heat of the sun for an hour, attained a temperature of 105°, and lost its odour; but, when shaken with the deposit, the odour was most offensive, and the presence of sulphuretted hydrogen still more decisive. The deposit contained abundance of sulphides, which, on examination on eight successive days, gave characteristic evidence of the separation of sulphuretted hydrogen.

Sample A.—July 13th. Taken from near St. Giles's Church, is disinfected at Tavistock-street.—The sewage was yellowish in colour, and the deposit yellowish grey. The smell was only that of gas-tar, very slight indeed. Even after four days' exposure to the hottest sun, no putrid gases were evolved. With the exception of the 15th of July, when there was a slight smell as of sewage, but no sulphuretted hydrogen, there was not any indication of the liquid with its deposit being of sewer origin. But it should not be omitted that sulphides were present in small quantities in the deposit.

Sample D.—Taken from Tottenham-court-road, July 13th, above the opening.—This corresponds with sample B, and the remarks are very similar, with the exception that the specimen was of a far more offensive character, and far more dangerous to health. On several days (16th, 20th, and 21st) lead paper was instantly blackened on exposure to the gases evolved; the chief offensiveness residing in the deposit.

Sample C.—Taken from St. Giles's Church sewer, July 13th, evening. Disinfected in Tavistock-street.—Not quite so yellow as A, contained more deposit, and the latter more sulphides. No odour except of tar, and none evolved even after four days' exposure to the hottest sun. Not a trace of hydro-sulphuric acid discoverable on any day between the 13th and 21st inclusive.

Sample F.—Taken from Tottenham-court-road, above the opening, July 14th.—Similar to B and D, but became still more offensive and injurious than D. Thus on the 21st, lead-paper was completely and instantaneously blackened on immersion in the air over the liquid in the bottle.

Sample E.—Taken from St. Giles's Church sewer, July 14th, disinfected in Tavistock-street.—This sample cleared with difficulty, and when delivered evolved neither sulphuretted hydrogen nor other offensive odour; but, in time, it afforded evidence of incomplete disinfection. Sulphides were distinctly present in the deposit, as in samples A and C, and exposure to hot sunshine for six hours on four occasions evolved traces of sulphuretted hydrogen. On the 15th there was a slightly offensive odour; on the 20th the smell was more decisively unpleasant; on the 21st there was neither smell nor free sulphuretted hydrogen.

It must, however, be observed that the severe trials to which this and other samples were exposed were quite exceptional, and impossible *en masse* either in the sewers or in the bed of the river. Thus, a portion of this very sewage marked E, which never attained to a higher temperature than 82°, had neither unpleasant smell nor evolved sulphuretted hydrogen.

Sample H.—Taken from Tottenham-court-road, above the opening, July 15.—Very similar to B, but rather more offensive, owing to more free sulphuretted hydrogen, and a larger presence of sulphides in the deposit. Exposed to a hot sun for four days, evolved sufficient sulphuretted hydrogen so as to turn lead-paper dark brown, and a further odour of a most offensive nature. By way of comparing results, it may be remarked, that this sample kept in a cool place for sixteen hours, where it attained to a temperature of 70°, evolved on standing but little smell, and communicated only a faint tinge of brown to the edges of lead-paper; but on shaking (and certainly motion may be considered the normal state) the smell became abominable, and lead-paper was immediately turned dark-brown.

Sample G.—Taken from St. Giles's Church sewer on July 15. Disinfected in Tavistock-street. Examined on the 16th.—It was of yellowish colour, with pale reddish-grey precipitate. No disagreeable smell, and no free sulphuretted hydrogen; but sulphides notably present in the deposit. Exposed to a hot sun for four days in close vessels, slight odour, and trace of sulphuretted hydrogen; but, placed under exactly similar circumstances as sample II—on the night of the 20th

and morning of the 21st—for sixteen hours, neither smell nor trace of sulphuretted hydrogen evolved.

Sample I.—July 15. Taken from sewer at Charing-cross. Disinfected in Tavistock-street.—Light yellow colour, with slate-coloured deposit. No disagreeable smell, and no free sulphuretted hydrogen; but distinct presence of sulphides in the deposit. After four days' exposure in close vessels to the hot sun, a slightly disagreeable odour perceptible, arising in part from a trace of sulphuretted hydrogen, which tinges the edges of lead-paper. Even in a cool place the smell, though slight, is unaltered, and this is owing, in part at least, to a trace of sulphuretted hydrogen. The evidence is conclusive as to absence of a sufficiency of the disinfectant, equally conclusive as to the very favourable difference between this sample and the one not disinfected.

Sample K.—Taken from St. Giles's Church sewer, July 16. Disinfected in Tavistock-street.—Of light yellow colour, and tarry smell; it contains no free sulphuretted hydrogen. Mere trace of sulphides in the deposit. Exposed to the hottest sun for four days, it underwent no change. On 21st July still perfectly sweet.

Sample L.—Taken from Charing-cross sewer, July 16. Disinfected in Tavistock-street.—Slight odour besides that of tar. Has the appearance of insufficient disinfecting liquor. This is proved by the fact, that when exposed to a hot sun it evolves traces of sulphuretted hydrogen. On the 21st July there is still a trace of free sulphuretted hydrogen and of other smell.

It would seem, then, to be quite within the reach of possibility to prevent altogether the evolution of nauseous gases from London sewage; and although we have still much to learn with reference to the character of gases which are not recognisable by the sense of smell, we have positive proof, from these and previous experiments, of the effectual action of Messrs. Smith and MacDougall's disinfectant upon several of the known gases.

It is with no desire to interfere with the official reports, but, as I have said, because of my long and intimate acquaintance with the subject, that I venture to address this letter to you. I know that the plan is a complete solution of the question which has so long agitated the public mind, and it appears to be the only one of the three hundred plans which have hitherto been able to stand inquiry. The treatment of the sewers along their whole line is a part of the plan of disinfection due to Dr. Smith, and it is so large and comprehensive that no time should be lost in beginning it. Add to this the regular watering of the streets with very dilute solutions of the disinfectant, a plan which I originally suggested, and the gases arising from their extended surfaces will be kept within proper bounds.

Equally easy will it be, by a proper expenditure of money, to prevent the Thames from continuing a most dangerous nuisance. But it can never be affected by ever so many weeks' expenditure of 1500*l.* in lime and chloride of lime at the mouths of sewers. We must adopt some such agency as is ready to hand, in the innumerable steamers which are keeping in perpetual circulation the sediment in the Thames. These we must employ in their ordinary journeys to diffuse the disinfectant, and I will venture to say the purification can be accomplished within a week. When all this shall have been done, the foul air which now threatens disease in London will be removed, and none will be generated to fill its place.

St. Mary's Hospital.

ON SOME OF THE DIFFICULTIES ATTENDING UPON THE TREATMENT OF STRICTURE OF THE URETHRA.

By HENRY SMITH, F.R.C.S.

In the *Medical Times and Gazette* for August 21 of last year, I detailed at length a case of obstinate stricture of the urethra, which was remedied by dilatation, and careful general treatment, after the patient had been condemned to undergo the operation of external division of the canal by a Surgeon of large experience, under the idea that there was not any other method of relief. At that time I made some

observations referring chiefly to a feature of difficulty which the case detailed particularly illustrated, namely, the almost insuperable rebelliousness to dilatation, which is every now and then met with in certain instances of this affection. I was enabled to show that a case of the most obstinate and unpromising nature might, by careful treatment, be made to yield, without recourse being had to the knife, although both the patient and his Surgeon were convinced that it was the only remedy. This incapacity of certain kinds of stricture to admit of progressive and satisfactory dilatation, is a feature well known to all those who have seen much of the disease in question; but there is one feature in particular to which I shall refer to in these observations, and which I do not find much allusion to in the ordinary works on stricture, and this is the absence of improvement in the power of passing the urine, although dilatation has been carried on in a satisfactory manner. This is a difficulty which is exceedingly annoying and distressing, because, in the first place, the patient naturally expects that relief will be given so soon as an instrument of at least a moderate size can be introduced into the urethra, and the Surgeon knows that he has to deal with a feature in the complaint which may depend upon circumstances over which he has little control, and which will render the treatment of the case more troublesome. Mere density or tightness in a stricture acting as a bar to progressive dilatation, is a condition much less likely to hinder a satisfactory termination than the one alluded to; for in the one case, although the dilatation may advance but slowly, the improvement in the stream of urine is generally commensurate with the mechanical progress, and satisfactory both to patient and attendant, while in the other it will happen that the exercise of the utmost skill and endurance is but faintly rewarded.

Next to extreme irritability of the urethra, this one feature of absence of improvement in the stream, has been a source of greater difficulty and annoyance than anything else. Among a considerable number of very severe cases of stricture which have lately been under my care, my attention has therefore been much directed towards ascertaining its cause, and removing the symptom, if it may be so termed. In some cases it has not been difficult to account for it, as where one or more fistulous sinuses exist; when such is the case the bladder may be healthy and the urethra be fairly dilated, yet the patent condition of the artificial openings, which take so long to close, allows the greater portion of the urine to percolate through them, little comes through the urethra, and that little in any volume. In instances of this kind the patients may be assured that the stream of urine will increase as the sinuses close up, slowly as that event is too often known to take place.

There are, however, other cases of severe stricture, uncomplicated with fistulous openings in the perinæum, where the Surgeon has been able to carry on dilatation in a satisfactory manner, and to such an extent that a good-sized catheter may pass, and yet there is either no improvement at all in the stream, or, if any, it is so slight as to be almost inappreciable. This obtains also not only in instances of stricture in persons of advanced age and of debilitated power, but it is occasionally met with in patients either in the very prime of life, or in those not much above adult age. It is in some of these latter cases that it is extremely difficult to understand the meaning of this symptom. It is considered by some men of large experience that it is the bladder alone which is in fault; that it has become weakened and dilated by the persistence of the obstruction in front; and that, even when this latter has been removed, the viscus does not recover its tone sufficiently to expel its contents in an effectual manner. That this is the true solution of the question in some instances there cannot be much doubt; but I am induced, by careful observation, to believe that in a considerable number of these cases the loss of power in the bladder is more apparent than real, and that the impediment to the volume and flow of the urine is in the urethra itself, notwithstanding that dilatation has been carried on to a measure with which the passing of urine in a small stream, or in drops even, seems almost incompatible. I have noticed that this very distressing feature has existed both in instances where the stricture has been exceedingly difficult to penetrate, the canal not being especially irritable, and in those cases where there has not been very much difficulty in overcoming the obstruction; but the urethra has been extremely sensitive. I have, moreover, noticed, especially in the latter cases, that more

than a single stricture has existed; that there has been one near the meatus, or one or two inches from it; and as a rule, with but rare exceptions, the anterior stricture or strictures have been found to be most irritable and unyielding.

In such instances as these it is extremely difficult to overcome the irritable condition of the urethra, and to dilate the canal; and then, after this has been accomplished to such an extent that a No. 8 or 9 catheter is introduced, there is the mortifying result of little or no increase in the stream of urine, or even of a diminution in size. Now, I believe that in such instances, especially where the patients are young or the stricture has not lasted long, the fault is not in the bladder, but that that organ expels the urine with its wonted power, and that the fluid coming in contact with the irritable portion of the canal—although it has been dilated to the extent mentioned—causes it to contract forcibly, and thus produce the fine stream observed. Careful examination of the urine in these cases shows absence of any disease of the bladder; and moreover, it will be seen that, small as the stream is, it is expelled with considerable force and continuously; which circumstance will not be produced, I apprehend, by the mere action of the urethral muscular fibres, whether voluntary or involuntary. In a very well marked case of simple loss of power in the bladder lately under my care, in the person of a very fine young officer, all the symptoms of stricture were present; but there was hardly any impulse at all given to the urine as it was being evacuated, and the patient was compelled to strain violently. There was not the least obstruction in the urethra itself, and by well emptying the bladder artificially, and by attention to the general health, this viscus gradually regained its tone, as evidenced by the increasing size and force of the stream.

In the treatment of the cases I have been considering, much patience is required, both on the part of the Surgeon and the sufferer; for, as I have before stated, the latter is too apt to be greatly disappointed at the little improvement which is perceptible, and in his distress is too liable to be misled into undergoing some heroic treatment which may either destroy his life, or give relief merely for a brief period. It is only by the continuous dilatation of the diseased canal to as great an extent as it will admit of, that the result so much desired will be obtained. If the patient is not advanced in years, or has not had stricture for a long time, he may be assured that a persistence in the treatment will be attended with satisfactory results; sometimes the desired relief will happen suddenly, at other times, and most frequently, the increase in the power of urinating will be only gradual, but will not be marked until an instrument of considerable size has been introduced. When, however, the features of the case indicate that the want of stream is due to a loss of power in the bladder, a long time elapses before the organ recovers itself, although the urethra has been well dilated by the Surgeon, and is kept patent by the sufferer himself. It is especially important in these cases to attend to the general health; for it will not unfrequently be found that this has suffered much, and that the loss of power in the bladder is but a symptom as it were of constitutional debility, rather than the mere result of an obstructed urethra.

The case I now briefly detail will illustrate some of the foregoing observations:—

A gentleman, aged 23, consulted me February 14, 1858, for stricture. On examination I found that the urethra was remarkably irritable, and that there was a stricture at the bulb, through which I could only pass a No. 1 wax bougie. The strictured portion of the canal was most remarkably sensitive, and readily bled. I ascertained also that there was a stricture two inches from the meatus. The health of this patient was good; but the bladder was very irritable, and he was only able to pass his water with severe smarting, and in a fine stream. Urine acid but clear.

On inquiring into the patient's history, I found that he had had stricture for five years, and that soon after its appearance he had submitted to a great deal of catheterism with benefit; about one year and a-half since, finding his symptoms returning, he unfortunately consulted a notorious person, who passed instruments from time to time during the whole of the period: he made use also of caustic, and upon the patient complaining that he had great irritability of the urethra, and nocturnal emissions, this worthy practitioner told him to have sexual intercourse regularly three times a-week. This injunction was readily obeyed for three months, at the

end of which time the patient's eyes began to be opened, and he resolved to take other advice. In order to show how this poor young fellow had been trifled with, I may mention that he brought to me a Britannia metal sound, equal to a No. 6, which he had been told to pass for himself.

It was evident that in this case the symptoms were due as much to the extreme irritability of the urethra, which had been induced by the wretched treatment he had undergone, as to the mere mechanical obstruction; and therefore it was necessary to relieve this, and at the same time endeavour to dilate the stricture in the most gentle manner. I therefore commenced the treatment by giving large doses of acetate of potash and tincture of hyoscyamus, and employed the wax bougie as a dilator.

Without entering into minute detail, I may mention that at the end of four weeks I was enabled to pass a No. 4 silver catheter, but the irritability of the bladder and urethra was excessive. In another fortnight I was able to pass only a catheter one size larger, but the irritability was distressing, and there was no improvement in the stream. I was careful to be very gentle in my manipulations, nevertheless this want of improvement was disheartening to the patient, although the dilatation was progressing, and he placed himself under the care of another Surgeon, and I saw nothing more of him until the beginning of June, when he again consulted me. He informed me that several catheterisms had been performed upon him, at first with success, but on the last occasions the Surgeon had not been able to introduce the instrument.

I was able to pass a No. 3 silver catheter, and by the end of the month had got so far as No. 8, but the distressing irritability continued, and there was not any improvement in the stream of urine—it was passed forcibly, but in a small thin volume—by August 1 we were still only at No. 8, for inflammation of both testicles had followed the use of instruments, and I was obliged to desist for a time—the stream of urine was only equal to a No. 2 catheter.

On the 18th I managed, with difficulty, to introduce a No. 9, but the sensibility at the seat of stricture was extreme, and the contraction near the orifice impeded the instrument.

21st.—Stream better since the introduction of No. 9, and it continued improving. I subsequently divided the anterior stricture, and was enabled to pass as large an instrument as a No. 12. Found after I had passed this once or twice the stream became larger than it had ever been in his life, the irritability of the urethra disappeared, and he left me in the middle of October quite well and able to pass a No. 10 catheter for himself.

This gentleman called upon me March 21; he informed me that he had no trouble with his stricture at all, and I saw him introduce a No. 10 catheter into his bladder with ease; he adopts this necessary precaution once a week.

This case, although sadly mismanaged at first, illustrates the position I wish to maintain in this paper, that there may be no improvement in the power of passing the urine, although the stricture may have been well dilated, and yet that the desired relief, though tardy, will be brought about by continuous dilatation and employed to its fullest extent. It appears to me also that this case opposes the view of those who maintain that in all such instances the diminished stream, with a patent urethra depends upon a loss of power in the bladder. Had this been so, the relief which at once appeared after a No. 9 catheter had been passed, and especially after I had divided the slight stricture at the orifice, would not have occurred so suddenly. I attribute the absence of improvement in the power of micturition for so many months, to the extreme irritability and contractibility of the canal which was only overcome by the most persevering use of dilating instruments. It might be objected by some that the continual employment of instruments in the irritable canal will only lead to keep up the very excitement we intend to allay. If instruments are passed roughly, or if the attempts to increase their size are made too rapidly, I believe that the painful condition of the parts and the constitutional sympathy will be increased; but it is far different when gentle and very gradual dilatation is adopted,—the morbid sensibility of the urethra is allayed, and in course of time entirely destroyed. A practical acquaintance with this fact is of value, not only in the treatment of stricture, but is to be made the most of in the treatment of stone by lithotripsy; for an irritable urethra here is more a bar to success than where a stricture is concerned; but it is well known that the

canal may be rendered comparatively insensitive by the cautious introduction of a sound several times prior to an operation being performed.

This is just one of those cases where the patient might have been easily led into the belief that perineal section was the only remedy. In fact he had been informed on one occasion since his first consulting me, and when the difficulties alluded to were at their height, that cutting would have to be resorted to. I doubt not that many of those unfortunate persons who have submitted to this operation, have been in much the same state as this patient was in for the first few months of treatment, being induced to do so by the belief that the increase in the stream of urine would only be arrived at by laying open the canal.

Sometimes it happens that in a severe case of stricture the earlier attempts to dilate are attended with an improvement in the stream which is satisfactory to the patient. Then this improvement ceases, and does not show itself again for a long period, although the dilatation may be steady and progressive. When such a circumstance occurs there can be no doubt that the bladder is not in fault; but that it depends upon the irritability of the urethra, or an insufficient dilatation of the stricture. Without going into details, I may mention a case of a patient, aged 45, who was under my care from December to April; the stricture was of fifteen years' standing and situated in front of the bulb. Treatment at the hands of various Surgeons of experience had been pursued, one of whom had performed internal incision on two occasions. The urethra, moreover, had unfortunately been wounded on one occasion through the stilet of a gum-elastic catheter escaping from the instrument. I commenced the treatment of this difficult case by dilating with silver catheters. The size and power of the stream of urine increased in proportion with the instruments, until I had got up to No. 4 and 5; but subsequently to this there was a good deal of irritation, and when a No. 8 or 9 had been introduced, the stream of urine was not larger than when a small instrument had been passed. Dilatation was, however, patiently persisted in, and after No. 10 had been introduced the size of the stream again increased and continued doing so until I had arrived at No. 13, when I dismissed him, able to pass his water in a good stream.

This case is interesting, as illustrating not only the particular point I have been dwelling upon, but it shows also how utterly useless is the practice of internal incision, in remedying a stricture for any length of time.

The practice of external division of stricture, which a misapprehension of some of the symptoms and an insufficient reliance upon the power of dilatation and other agents, was the means of bringing into use a few years since, has now been proved beyond all doubt to be so dangerous to life, and so inefficient to produce the complete remedy once so vaunted, that it may hardly seem necessary to consider this subject here; however, notwithstanding that the operation has received the *coup de grâce*, still it may be well, for the sake of those who seek information, to mention any facts appertaining to it.

It will be seen by referring to this Journal of November 20, 1858, that I detailed the particulars of a case of stricture which had recently been under my care, and where the operation of external division had been performed by Mr. Syme himself only some seven or eight months before. This gentleman, under 30 years of age, was in a wretched condition, with a most irritable stricture, a fistulous opening in the perinæum, and broken-down health. Now I will contrast this case, which had been operated upon, with the present condition of the case to which I referred to in the opening words of this paper, and where the patient of about the same age, and suffering so severely as to have retention every day of his life and to be compelled to carry a bougie with him wherever he went, was to have been cut. Immense difficulties were overcome, and this gentleman left me last August with his urethra well dilated, and able to pass a large catheter himself. Wishing to know his present condition I got a letter from him, dated May 7th; he says:—"My general health is perfect. I regularly pass once a week a No. 9 instrument, which I am able to do without causing any bleeding. I can retain my urine as long as any one, and am never troubled by getting up at night. I never suffer from retention of urine."

I may mention that this gentleman is not in a particularly favourable condition for the subjugation of a stricture, he

being in the Horse Artillery, and thus compelled to take much equestrian exercise.

About a fortnight since I had in my house, on the same morning, two unfortunate gentlemen, in the prime of life, who had undergone the perineal section; one, five years since, at the hands of a London Surgeon of large experience; the other, three years previously, had been cut by Mr. Syme himself in Edinburgh. They were both in a wretched condition, the one had his perinæum riddled with three fistulous openings; but as Mr. Syme himself was not the operator here, the proceeding was of course unskilfully and improperly done, and I will say no more about it. The other case, however, was treated by Mr. Syme himself, and the operation was of necessity done according to the rules laid down by that Surgeon. Yet, where is the complete remedy? The unfortunate gentleman assured me that before he left Mr. Syme's care after the operation, he felt the stricture returning, and that notwithstanding he persisted in passing the instrument every fortnight, as he was told to do, the canal contracted, so that he was unable at the expiration of ten months to pass anything at all. Since then he has been roaming about from one Surgeon to another, in the hope of getting his stricture dilated. When he first consulted me some six weeks since, I could only with the greatest perseverance succeed in introducing a small No. 4 catheter, although a distinguished Surgeon in Dublin had introduced a No. 8 only a fortnight previous. There was no fistulous opening left here, as in the other; but there is the irritability and contractility of the urethra as before, although Mr. Syme performed the operation himself, and according to the information given to me by the patient, assured him it would be a certain cure. I have before enunciated the opinion that not only does this operation not prevent the return of the stricture, but that the re-contraction becomes more severe than before. As I had not the opportunity of seeing this gentleman before he was cut, I cannot positively state whether this holds good here or not; but that the induration still remained, or had reformed at the site of the old disease, was quite evident by running the finger along the perinæum. Cutting cannot possibly get rid of this; and so long as this remains, the stricture will persist.

Caroline-street, Bedford-square.

THE LONDON

PRACTICE OF MEDICINE AND SURGERY.

SAMARITAN HOSPITAL.

THREE CASES OF OVARIAN DISEASE.

OVARIOTOMY—

IODINE INJECTION—SIMPLE TAPPING.

(Under the care of Mr. SPENCER WELLS.)

SINCE the three cases of ovariotomy reported at pages 11, 31, and 59 of the present volume, Mr. Wells has had six cases of ovarian disease under his care in the Samaritan Hospital. In four of these cases tapping only has been had recourse to, merely as a palliative measure to relieve the patients from the pain and impeded respiration caused by the presence of a large quantity of fluid. Three of these women have left the Hospital, temporarily relieved. They will probably return and form the subject of future reports. The other three cases have terminated, one in death, the other two in recovery; and it is interesting to observe that the fatal case was that in which the merely palliative measure of tapping was adopted, while in the two which have terminated successfully, a radical cure was sought for, in one by ovariotomy, in the other by the injection of iodine. We append a short abstract of each of these cases, condensed from the very full notes taken daily in the Hospital book by Mr. Phillips, House-Surgeon.

Case 1.—COMPOUND OVARIAN CYST—TAPPING—DEATH FROM SUPPURATIVE INFLAMMATION OF THE CYST.

A. D., a cook, aged 43, admitted July 23, 1859.

History.—Mother died of cancer of the uterus, but she has seven brothers and three sisters all healthy. Catamenia regular up to age of 30, but have only appeared six or seven times since, the last time being five or six years ago. First noticed enlargement of abdomen three years ago, but she did her work as a cook until last September. She was admitted into

St. George's Hospital on the 1st of December under Mr. Hawkins, who in April removed two gallons of coffee-coloured fluid. She left; and was readmitted on June 14th. On the 27th Mr. Hawkins tapped her the second time, and removed twenty pounds of a lighter coloured fluid. She complained of great pain and aching afterwards, and nothing more was done until her admission to the Samaritan Hospital.

State on Admission.—A tall, strongly-built woman, of dark sallow complexion, with an eruption of acne on the face and forehead. The abdomen is occupied by a large multilocular ovarian cyst. The circumference at umbilicus is four feet; measurement from ensiform cartilage to symphysis pubis, two feet. Bowels generally confined. Urine small in quantity, containing no albumen. Pulse feeble; action of heart and lungs much impeded by the distention of the abdomen.

Progress of the Case.—Looking to the condition of the tumour alone, the case appeared to be a very favourable one for ovariotomy; but taking into consideration the feebleness of the pulse, the want of appetite, and the cutaneous eruption, Mr. Wells decided to tap only, and then, if the general health should improve, to consider the question of ovariotomy. Accordingly on the 26th of July he removed eighteen pounds ten ounces of coffee-coloured fluid from a large cyst, which, when empty, appeared to be surrounded by others. These, however, were not opened. The dyspnœa was greatly relieved. The puncture made by the trocar was closed, but during the night she felt "something give way inside," and fluid began to ooze from the opening.

July 27.—Thinking that a second cyst had given way into that which was tapped, Mr. Wells introduced an elastic catheter through the trocar puncture, and removed about three pints of fluid. The catheter was left in for about four hours, but was withdrawn, as it caused slight uneasiness.

28th.—She remained pretty well all day, oozing still continuing from the orifice; but at 10 p.m. she had a sudden severe rigor, followed by a hot stage and sweating.

29th.—Feverish; rapid small pulse; scarcely any pain or tenderness in abdomen; nausea and occasional vomiting; a few pellets of pus and lymph appear in the fluid which oozes away.

During the next three days she remained much in the same state, becoming more nervous and lower, and occasionally delirious; vomiting being very troublesome, and diarrhœa reducing her still more. She took brandy or sherry with soda-water, champagne, etc., but gradually sank and died on the 3rd of August, eight days after the tapping.

The body was examined six hours after death. The tumour was connected to the parietes by adhesions, which were easily broken down. A portion of omentum was separated, and then the tumour was turned out. The peduncle was formed by the right broad ligament; the left ovary was healthy. There was a small fibrous nodule at the fundus of the uterus. No sign of peritonitis. The lining membrane of the two largest cysts, which communicated with each other, was acutely inflamed, deeply injected, and covered in patches by a layer of pus and lymph. The lungs were healthy. A little clear serum in the pericardium; firm fibrinous clots in the cardiac cavities and large vessels.

Remarks.—The result of tapping an ovarian cyst is by no means so free from danger as some persons suppose. Many cases have been recorded in our Hospital reports in which death has followed this simple operation; in some by exhaustion or collapse; in others by cyst inflammation. Dr. West summarises 130 cases collected by Southam, Lee, and Kiwisch. Of these 22 terminated fatally within a few hours or in less than ten days after tapping. Of 31 cases of his own one died thirty-six hours after a second tapping, and two died of inflammation of the cyst within a few days after its first performance. In the case just narrated every precaution was taken against cyst inflammation. The fluid was evacuated slowly, and by the piston trocar and tube canula always used by Mr. Wells, so that ingress of air was prevented. When the second cyst opened into the first and the puncture reopened, it became a question whether this should be closed or all the fluid evacuated. The latter plan was adopted, as it was then too late to prevent ingress of air, and there was danger both of retention of decomposing fluid within the cyst, and of its escape into the peritoneal cavity if the integumental opening were closed. Cyst inflammation in a woman depressed by long-standing ovarian disease must, under any circumstances, prove a very formidable affection.

Case 2.—UNILOCULAR OVARIAN CYST.—TAPPING.—REFILLING OF CYST.—IODINE INJECTION.—SUCCESSFUL RESULT.

M. S., aged 50, married, first admitted January 24, 1859. Two years ago she began to increase in size, and during the last four months the increase has been very rapid. On admission she had all the signs of a large, non-adherent unilocular ovarian cyst. On the 28th of January Mr. Wells tapped the cyst, and removed eighteen pounds of a thick fluid, sp. gr. 1006. Dr. Hewitt's exploring sound was used, and no inner cysts could be felt. It was decided, therefore, to see what the result of the simple tapping would be, followed up by pressure. No ill effects followed the tapping. The patient was supplied with an abdominal belt, and left the Hospital early in February. She attended occasionally as an out-patient, the cyst refilling gradually, and was readmitted July 7th. As she was in a very fair state of health, and there was still every appearance of the cyst being unilocular, Mr. Wells decided, after consultation, to empty it, and inject iodine. Accordingly, on July 13, he removed thirty pounds twelve ounces of clear fluid through an elastic catheter, passed along the canula of a large trocar to the bottom of the cyst. A solution of two scruples of iodine, and one drachm of iodide of potassium, in an ounce of rectified spirit and an ounce of water was poured through the catheter to the bottom of the cyst, when this had been emptied as completely as possible. The catheter was then withdrawn and the canula afterwards, thus diminishing the chance of any drops of the iodine solution passing into the peritoneal cavity. A little pain followed the injection, but it was relieved by a hot poultice and a grain of opium.

The next day she was evidently under the influence of iodine. It was passing off in the breath and urine, and she complained of its disagreeable taste. The pain in the abdomen continued, but it was very slight; the iodine appearing to act as a narcotic. The pulse was 140.

On the following day the pulse was down to 126. Pain only felt on pressure; otherwise the same.

Third day. As she complained of flatus, which was distending the intestines, a turpentine enema was used and followed by much relief.

On the fourth day the note is "Weak and low, but no pain." Four ounces of wine ordered. On the fifth day some appetite returned, and the next day she got up. Beer was given in addition to wine on the seventh day, and a little brandy and soda-water occasionally, as she felt at times faint and weak. During all this time the cyst could be felt below the umbilicus, freely moveable from side to side, about the size of a closed fist, but fluctuation could not be detected. On the 1st of August the note was, "Still weak, but rapidly gaining strength. Eats, drinks, and sleeps well. Pulse 92." She left the Hospital on the following day, nineteen days after injection, with no sign of any re-accumulation of fluid; but, on the contrary, with every prospect of the cyst being obliterated and contracting.

Remarks.—It is obviously premature to record this case as more than one of *probable* success; but the progress has been so similar to one recorded at page 548 of our last volume, where the success has been quite complete, that the prospect is encouraging. The woman just alluded to was in the Hospital a few days ago, and appeared to be in perfect health, while no remains even of the cyst could be detected. In that case only thirteen pints of fluid were evacuated. In this case the cyst was much larger, and Mr. Wells injected double the quantity of iodine he used in the first case. In both cases it was of the same caustic strength, and was all left in the cyst.

Case 3.—COMPOUND OVARIAN CYST.—OVARIOCTOMY.—CONVALESCENCE.

J. A., aged 47; married; admitted June 22, 1859.

History.—Married two years and a-half ago, having been employed as a housemaid thirty-three years previous to marriage. Generally had good health. Catamenia regular up to the age of 43, when they ceased, and only appeared once since, two years ago. Nine months after marriage noticed some enlargement low down in the abdomen, and to the right side. She thought herself pregnant, and did not go under treatment for nine months longer. At that time she was treated for constipation; but swelling and pain increased until January last, when she applied to Mr. H. Smith at the Westminster Dispensary, who detected ovarian disease, and

tapped. She filled again, and was tapped nine weeks after the first tapping. The third and fourth time the cyst filled at intervals of only three weeks; the fluid in each case being dark coffee-coloured.

State on Admission.—A middle-sized, hectic-looking woman, suffering from great pain both in abdomen and back, dyspepsia, and impeded respiration. A large ovarian cyst occupies the whole abdomen, and hard globular masses can be felt in the walls of the cyst on both sides.

Progress of the Case.—As she was very weak and restless, suffering from great pain, and a tendency to vomit, Mr. Wells decided, after consultation, to give some present relief by tapping, and then to endeavour to bring the general health up to a point at which ovariectomy might be performed with a better prospect of success. Accordingly on the 26th of June he removed eleven pounds of very thick fluid, which contained a great deal of decomposed blood, and coagulated fibrin. (This was afterwards explained by the fact that there had been a good deal of bleeding after the previous tapping.) She suffered from flatulent distention of the intestines for some days, and there was some bleeding from the uterus. This was found to depend on a small polypus growing from one side of the canal of the cervix. Mr. Wells removed the polypus by torsion. During the next month she was put upon a liberal diet, with wine and beer, and improved so much in general health, that it was decided, after careful consultation, to accede to the patient's wish to have ovariectomy performed.

July 25.—Chloroform was administered by Mr. Armstrong Todd, who used his new inhaler. Mr. Wells made an incision from five inches above the umbilicus, carrying it downwards in the median line to two inches above the symphysis pubis. One small artery was tied near the umbilicus. The peritoneum was divided along the whole extent of this wound as soon as the bleeding had ceased. Extensive adhesions to the parietes on both sides were then broken down by the hand, and the cyst emptied by a large trocar. Adhesions to omentum and small intestine were then carefully separated, but before the cyst could be withdrawn, it was necessary to separate adhesions on the left side, by which the broad ligament, sigmoid flexure of colon, and Fallopian tube, were united with the cyst walls. The right ovary was that diseased, and the peduncle was formed of the right broad and round ligaments and Fallopian tube; but the left Fallopian tube was much thickened and elongated, and firmly adherent to the back and lower part of the cyst, where the colon was also firmly attached. All these adhesions were broken down, the pedicle secured by a clamp, and the cyst cut away. There was then very free bleeding from several points where the cyst had been attached, and ten vessels had to be tied. Three of them were on different parts of the left Fallopian tube, and as this appeared to be so large and thick, and the left ovary (probably atrophied) could not be found, the tube was tied to the clamp, and fixed outside the lower part of the wound beside the peduncle. The wound was then united by harelip-pins and superficial sutures, as in the cases previously reported. The ligatures were brought out about the centre of the wound.

The tumour was found to consist of one very large cyst, with a number of smaller cysts and masses of semi-solid, pseudo-colloid substance, in its walls.

It is unnecessary to follow the daily record of the case after operation, as it is merely one of almost uneventful recovery. Warm linseed-poultices were kept on the abdomen. An occasional enema of twenty drops of laudanum in two ounces of water was given when there was a little pain. The pulse varied from 90 to 112 during the first week. There was no vomiting till the third day. The harelip-pins were removed on the third day, and the superficial sutures on the eighth. The wound united by first intention. The clamp was removed, and the bowels opened by warm-water enema on the fifth day. During the second week the only annoyance was from accumulation of flatus in the intestines, which was removed by the use of warm-water enemata. She had taken very little nourishment at first, but she soon began to take beef-tea, soda-water, and brandy, wine, and then the *mistura vini gallici*. On August 5, two grains of quinine were given three times a-day, and on the 8th the dose was increased to three grains, as it seemed to have a good effect in diminishing the flatulent distention of stomach and intestines.

August 10.—Four of the ligatures have not yet separated

and there is some purulent discharge beside the tube; but she eats, drinks, and sleeps well; the bowels and kidneys act well. She sits up in bed, and may be considered as convalescent.

Remarks.—The chief peculiarity in the progress of this case after operation was the absence of vomiting. In all Mr. Wells's previous cases vomiting has been the most distressing symptom. The recommendation to give ice, or ice and opium, for some hours before operation, was tried in seven cases, but proved utterly useless. Ether was given instead of chloroform in one case also without any good effect. In his earlier cases, Mr. Wells gave opium every four or six hours, or equivalent doses of morphia by suppository, keeping the bowels confined for eight or ten days after operation. But thinking that this kept up sickness, and that the constipation led to flatulent distention, he discontinued this practice, only giving opium by enema in small quantities occasionally, when it was called for by pain, having the bowels opened about the fourth day by enema. The results of this treatment, combined with the constant use of hot poultices to the abdomen, have been most satisfactory. The patients have been in a far more natural state than before, suffering less from depression, nausea, pain, or flatulence, while the pulse has not been so rapid. Still the vomiting has been troublesome, and Mr. Wells determined to discontinue the use of ice before operation. It was not given in this case, but it would be unfair to attribute the absence of vomiting to this omission, as Mr. Todd finds that he is enabled by the use of his inhaler to keep patients narcotised by so small a quantity of chloroform that vomiting is rare. Further observation, however, is needed to settle this important practical question.

This case makes eight in which Mr. Wells has performed ovariectomy. Six of the eight have proved successful.

HOSPITAL NOTES.

SUBCUTANEOUS RUPTURE OF THE LONG SAPHENA.

An interesting case has recently been under Mr. Bryant's care in Guy's Hospital, in which the long saphena vein gave way spontaneously without ulceration or rupture of the overlying integument. The patient was a woman, aged 36, who had borne a family, and was the subject of large varices in the legs. She came to the Hospital with the statement that on the previous evening, while sitting at the table, she suddenly felt something give way, and found a large and increasing swelling. On admission the swelling, which occupied the inner part of the left thigh, just above the knee, was as large as might be supposed to contain one or two pints of fluid blood. The nature of the accident was evident. The woman was kept quiet in bed, and the blood was in a short time absorbed.

SECONDARY SUBCUTANEOUS HÆMORRHAGE AFTER A BRUISE.

In the above we have an instance of subcutaneous rupture of a vein; in the following, which came under observation at the same time, the vessel implicated was in all probability an artery. A muscular young man received a severe kick on the outer side of the thigh, for which he attended at Guy's Hospital. Ten days afterwards suddenly a large swelling formed. He was now admitted under Mr. Birkett's care. The swelling was as large as a child's head, and evidently contained fluid, which was bound down beneath the fascia. Mr. Birkett made a small exploratory puncture, but obtained only a small quantity of pure blood. The opening was at once closed, and by degrees the fluid was subsequently absorbed.

TESTIMONIAL.—EAST LONDON MEDICAL AND SCIENTIFIC BOOK SOCIETY.—A silver salver, the value of £20, has just been presented to Andrew Holman, Esq. of John-street, Minorities, by the members of the above Society, bearing the following inscription:—"Presented by the members of the East London Medical and Scientific Book Society, to their Honorary Treasurer and Secretary, Andrew Holman, Esq. as a mark of personal esteem, and as an acknowledgment of his valuable services during many years, June 8, 1859."

THE PROVINCIAL PRACTICE OF MEDICINE AND SURGERY.

THE LIVERPOOL HOSPITALS.

DURING a few days' visit to Liverpool recently we had the pleasure of going through the wards of several of its excellent Hospitals. The following notes of the more important cases brought under our notice may be acceptable to our readers.

THE LIVERPOOL ROYAL INFIRMARY.

(Cases under the care of Mr. LONG, Mr. STUBBS, and Mr. BICKERSTETH.)

We were indebted to Messrs. Walker and Allen, the Resident Medical Officers of this Institution, for most of the details respecting the cases about to be mentioned.

RECOVERY AFTER FRACTURE OF THE PELVIS.

In one of Mr. Stubbs' wards was a man whose case is worthy of notice, as an instance of recovery after fracture of the ilium. He had been run over by a loaded cart carrying two tons, which passed over his hips. When admitted (April 1st), immediately after the accident, there was undue mobility in the pelvic bones, and crepitus could be produced. An irregularity in the rim of the left ilium showed that the seat of fracture was in that bone, and not more than a few inches from the sacro iliac synchondrosis. The patient was a short built man, of 29. During the first week of his sojourn in the Hospital he required the use of the catheter regularly, and some difficulty was occasionally encountered in getting the instrument into the bladder, owing to its appearing to impinge against an irregular projection in the pelvis. During his confinement to bed the man had an acute attack of pericarditis which threatened at one time to end fatally. When we saw him (July 28th, three months after the accident) he was about in the ward and able to walk well, though somewhat lame and complaining of a sense of weakness in the injured hip.

The body of the ilium is, we believe, one of the least usual positions in which fractures of the pelvis ever occur. Although such injuries are of course very serious, more especially in that they usually involve also those of important viscera, yet when confined to bone, recoveries after them not infrequently occur. We have repeatedly witnessed such in the London Hospitals, and have recorded several.

COLLES' FRACTURE OF THE RADIUS OCCURRING IN BOTH WRISTS.

It curiously happened that there were two cases in the Hospital exemplifying the occurrence of fracture of the lower end of the radius on both sides from the same accident. The subject of one was a man of about 50, that of the other an elderly woman. In both the usual history was given of a fall forwards, in which the hands had been thrust forwards to save the body and face. The man's arms had just been released from splints, and presented certainly much less of deformity than is usually seen after this troublesome form of fracture. We learnt that it was the practice at this Hospital to put up these fractures with the hand straight, not bent inwards, as is usually done, and as most authorities direct.

NON-UNION OF THE TIBIA AND FIBULA AFTER COMPOUND FRACTURE.

It is certainly very rare for compound fractures to end in non-union. Whether it be that fractures of the compound class are, as regards simple ones, comparatively rare, or that there is something in the nature of the injury which, should recovery ensue, renders union almost certain, we do not know; but it is certainly a fact, that although ununited fractures are far from infrequent, we almost never receive with them the history that the original injury was compound. A case now under the care of Mr. Bickersteth forms an exception to this remark, and almost the only one which has ever come under our notice. The subject of it is a bricklayer, aged 28, apparently in good health. Two years and a-half ago he received a compound

fracture of the right leg, about six inches below the knee, together with other severe injuries. He was treated in another Hospital, and made such favourable progress that at the end of nine weeks he was able to go out, which he did, with his limb still in splints, and against the advice of his surgical attendants. In all probability it was to thus prematurely leaving the Hospital that he owes his present condition. The wound in the skin healed over, but the bones did not unite, and he now has a false articulation of the most troublesome kind. For this he is now under Mr. Bickersteth's treatment.

EXCISION OF CANCER OF THE LIP—RECURRENCE OF THE DISEASE AT THE OTHER SIDE OF THE MOUTH.

We noticed some months ago a case in which cancer of the lip recurring after an operation did not attack the cicatrix left by the wound of the excision, but another part of the lip. Such cases are interesting, as proving a stronger constitutional predisposition, than many writers are willing to admit that this variety of epithelial carcinoma possesses. Another example of the occurrence,—and only the second, which as far as our memory serves us has ever come under our notice,—was presented by a patient now under Mr. Bickersteth's care.

The man, a sailor, is 55 years old, and ten years ago had a cancerous ulcer excised from his lower lip by Mr. Delagarde, of Exeter. The V shaped incision was employed, and a healthy cicatrix resulted, which still exists about an inch from the right labial commissure. The man now has a large open cancerous sore involving the left angle of the mouth and portions of the upper as well as the lower lip. He states that this recurred cancer has been gradually spreading during the past year. For nine years following the operation he was quite well. As far as he recollects the original sore had existed nearly two years before Mr. Delagarde cut it out. It may be suggested that the irritation of the pipe transferred since the operation to another part of the mouth has been the cause of the altered location of the disease; but here, as far as the man's account can be relied on, the evidence breaks down. He avers that he has smoked very little indeed since the operation, and not at all for the last five years. It appears that there is a family predisposition to malignant disease, for his mother, he states, died at the age of 65, of "what the Doctors called a crab-cancer," which had destroyed the greater part of her face. The man's health is still fair, though it has failed considerably since the recurrence of the disease, and Mr. Bickersteth intends to perform shortly a second excision, which from the size which the ulcer has been permitted to extend to, will of necessity be extensive, and require some transplantation of integument to fill up the gap.

RECOVERY FROM THREATENED PYÆMIA.

Another case, which was of some interest to us, was that of a man, in whom, as Mr. Walker, the House-Surgeon, informed us, recovery had followed after all the usual symptoms of pyæmia. A man, aged 27, was admitted with crushed toes and metatarsus. The wound became unhealthy, and about a week after admission the man had severe rigors, a stitch in one side, a rapid feeble pulse, pains in the joints, and that peculiar sunken aspect generally pathognomonic of a pyæmic state. For some days he was exceedingly ill, but no abscesses in joints or cellular tissue formed. By degrees the alarming symptoms subsided, and he is now convalescent. The remedies used were stimulants, quinine, opium, and chlorate of potash.

FEMORAL ANEURISM TREATED BY PRESSURE—SUBSEQUENT LIGATURE.

J. A. aged 28, a fireman, from the Cheshire Iron Works, was admitted on June 10th, under Mr. Bickersteth's care, for a large aneurism in the inner side of the left thigh. It was at the time, as Mr. Jackson informed us, about the size of a large fist. The man gave an account of having been struck on the part by the handle of one of his tools, but the accident had occurred at least eighteen months before he perceived the swelling. The latter had indeed only been noticed for about a month before he obtained admission into the Hospital. Mr. Bickersteth determined to give the pressure plan a trial, and a few days after the man's admission tourniquets were accordingly adjusted so as to command the femoral artery. Due arrangements were made for the

alternate use of the two instruments. On the third day, despite all precautions, a small slough had formed under the pad of one of them. At this time the tumour was much diminished in size and considerably solidified, indeed, for a few hours, it had been hoped that the pulsation had quite stopped. The appearance of the slough, however, necessitated the entire disuse of the tourniquets, and subsequently, although the man was kept strictly quiet, the aneurismal sac much enlarged. It should be added that he had, during the period of trial of compression, complained remarkably little of pain, and that even during the formation of the slough he had not suffered much. About three weeks after the disuse of the tourniquets, there suddenly appeared one morning symptoms of impending gangrene of the foot. The tumour had also greatly enlarged. A consultation was held, at which strong opinions were expressed that immediate amputation ought to be performed. Mr. Bickersteth, however, decided to try, in the first place, the effects of a ligature on the femoral. This was done. At the time of our visit, ten days after the application of the ligature, there appeared every probability that a favourable result would be obtained. The foot had regained its temperature and had lost its oedema, and the aneurism was much diminished in size.

THE COMPRESSION TREATMENT OF ANEURISM.

The Surgeons to the Liverpool Royal Infirmary do not speak very enthusiastically as to the general results which they have obtained from the compression treatment of aneurism. In no case have they been able to effect a complete cure by its means, although it has been resorted to repeatedly. Mr. Long in going round the wards made some instructive remarks upon this subject. He stated, among other points, that, in his experience, true popliteal aneurism was the exception rather than the rule. More usually the aneurism was a little above the popliteal space, and affected the artery just after it had escaped from Hunter's canal; sometimes, and not infrequently, it was above that canal (a). He believed that all anæmic patients were unsuitable for the trial of the pressure plan, to the success of which it was desirable that the blood should be well nourished and of good quality. To explain the want of success in Liverpool, as compared with Dublin, he was obliged, he said, to suppose that the Liverpool Surgeons had been unfortunate in their cases; and also believed that their having contented themselves with instrumental instead of manual compression had also had some influence. As far as instruments could go he was sure some of their cases had had every advantage. A late House Surgeon, Mr. Morris, formerly of St. Bartholomew's, had devoted the utmost attention night and day to the details of the management of some of their cases, which nevertheless had not succeeded.

Being in Dublin a few days later, we of course made the details and the results of this method of treating aneurisms the subject of special inquiry. Our Dublin *confères* have not only the credit of having brought it into use, but of having succeeded in a much larger proportion of cases than have the most successful of their imitators. We could not learn on careful inquiry that attention is given in any special manner to other points than those which have been had in constant observance in our English Hospitals. Of the two plans by interrupted and uninterrupted compression, the former we were told had been usually adopted, and was considered much the safer. The use of as little fluid as practicable was considered best, but no extreme prohibitions in this matter were commonly made. The Dublin Surgeons take that sort of pride in the compression cure of aneurism which always attaches to originators, and we have no doubt that this feeling induces an extra amount of attention to details in each case. In this method everything depends upon details and upon their patient and persevering development. No case of aneurism was under treatment in any of the Dublin Hospitals at the time of our visit, so that we had no opportunity for a personal inspection of the details of management in these matters.

CASE OF RECURRENT FIBROID TUMOUR FOUR TIMES REMOVED.

An interesting example of the class of fibroid tumours,

(a) The ordinary doctrine as to the infrequency of aneurisms in this position was undoubtedly expressed by Mr. Alfred Roberts in his comments on a case in our Hospital Reports last week, where he spoke of an example of it as interesting on account of rarity.

which exhibit an inveterate tendency to reproduce themselves after excision, while they neither cause enlargement of the glands, internal deposits, or induce cancerous cachexia, was afforded by a young woman under Mr. Bickersteth's care. She was aged 27, pale and anæmic, but showed no approximation to the "yellow leaf complexion," so often seen in the subjects of true cancer. As far as she knew, none of her blood relatives had ever suffered from cancer. The tumour had developed itself on the inner aspect of the right arm, nearly over the course of the vessels, and the original growth first appeared about five years ago. It had been excised four times, and on the last occasion, now six weeks ago, Mr. Bickersteth had removed a mass as large as two fists, which had been growing twenty months. Between the first and the second removals a year intervened, between the second and third only nine months, and between the third and the last two years. No argument could, however, be based on the length of the last interval, as to diminishing tendency to recurrence, as she had on this occasion allowed it to remain much longer without seeking surgical interference. It had, in fact, returned within four months of the previous operation. The young woman stated that she always improved in health after the removal of each successive tumour, and failed again during their periods of growth. In this circumstance we believe that the recurrent fibroids resemble cancers. Although not inducing any peculiar form of cachexia they appear to draw very largely on the nutritive powers, and greatly reduce the patient's strength for the time being.

TREATMENT OF SYPHILIS AT THE LOCK HOSPITAL.

The Liverpool Royal Infirmary, like the Edinburgh Infirmary, has no out-patients' department, nor does it admit venereal cases into its wards. Near to it, however, and connected with it in management is a Lock Hospital and Dispensary, which admits a large number of in-patients, besides having many who attend to be prescribed for.

The circumstance which most interested us in visiting this Institution, was to learn from Mr. McCheane, that the moist fumigation plan, as recommended by Mr. Langston Parker, had for some time been in full use. It is indeed the ordinary mode of treatment, and is adopted in all cases requiring the use of mercurials, although not to the exclusion of iodides, and mercurials exhibited simultaneously by the mouth. It would seem as if this plan were destined to become the invariable method of treating syphilis, and such, we feel assured, it well deserves to do. It has not yet obtained that recognition in our Metropolitan Hospitals which it merits.

THE LIVERPOOL NORTHERN HOSPITAL.

REVIVAL OF THE USE OF THE TREPHINE.

(Cases under the care of Mr. ELLIS JONES and Mr. CHALMERS.)

One of the points to which much attention has recently been directed is the class of cases in which the operation of trephining ought to be performed. The general feeling some few years ago was strongly opposed to that free use of this instrument, which prevailed among the older Surgeons. Now a reaction has again taken place, and it is again much more used than it was ten years ago. Foremost among the Surgeons who have urged the propriety of more frequent employment of it, is Mr. Ellis Jones, of the Liverpool Northern Hospital. He holds that symptoms ought not to be waited for, but that when the skull is fractured, and bone depressed, it is the Surgeon's duty at once to operate. That this revived rule of the older Surgeons is acknowledged also by some of the best of those at present holding appointments in the London Hospitals, several cases recorded in these reports during the last few years abundantly prove.

An illustration of the good results of this treatment was in the Hospital at the time of our visit. A lad of about 12 years of age was admitted, having sustained a compound fracture of the left parietal bone from a blow from the end of a broken chain. Portions of bone had been driven in, and cerebral substance in small quantities was scattered about the wound. Mr. Ellis Jones employed the trephine and elevator at once, although the lad was but very partially affected, as regards impaired consciousness. The subsequent progress was exceedingly good, and at present the wound is

just healed. The boy was admitted in March. Under the cicatrix the pulsations of the brain may easily be felt. The lad is up and about the ward, and the only remaining affections of the nervous system are a variable temper and a slightly drawn state of one side of the face.

EXCISION OF THE ELBOW-JOINT TWO WEEKS AFTER SEVERE COMPOUND FRACTURE.

The subject of this case is a woman, aged 46, under the care of Mr. Chalmers, who was admitted with a severe compound fracture of the radius and ulna a little below the elbow-joint. The skin and soft parts in front of the joint had been extensively lacerated, and the brachial artery had been torn through though without hæmorrhage. Amputation was advised, but the woman refused her consent, and Mr. Chalmers accordingly made an attempt to save the limb. The joint subsequently suppurated, and as the woman's health was giving way, an excision of the ends of the bones implicated was performed two weeks after the accident. A single long incision in the inner side of the ulna was adopted. The case has progressed very well indeed since the operation, and at present the patient has motion at the elbow, and a very useful arm is promised.

OTHER CASES, ETC.

Mr. M. B. Wall, the able House-Surgeon to this Hospital, to whose courtesy we were indebted for the particulars of the above cases, also directed our attention to several others of more or less interest. One of these was that of a man, in whom a large thoracic aneurism was presenting externally on the left side of the sternum; and a second that of a poor fellow, an Italian, who had been admitted the night before, having attempted suicide by shooting himself into the right ear, and in whom as yet no material cerebral symptoms had supervened.

Mr. Wall also mentioned to us a case in which paracentesis had been twice attempted without obtaining fluid. The disease was believed to be ovarian dropsy, and the patient, a young woman, had died a few days before our visit. At the autopsy the tumour was found to consist of soft cerebri-form cancer, in which many cysts had been developed. It filled the abdomen, and had yielded a sense of fluctuation, which it was impossible to distinguish from that of a large cyst.

Excision of the knee-joint had, we were informed, not been performed at this Hospital. At the Royal Infirmary Mr. Bickersteth told us that he had tried it in five instances, and that he had been much disappointed in his results.

NINE DRINKING FOUNTAINS, for the following sites, are to be provided by the Free Drinking Fountains Association, two by the Illuminated Indicator Company, and five by private individuals:—King's-cross, the Broadway at Camden-town, Brighton-street and Cromer-street, the Red Cap at Camden-town, Southampton Arms, Hampstead-road; Euston-road near the London and North-Western Railway Terminus; Tottenham-court-road, by Whitfield's Chapel; at the Brill, Somers-town, near the York and Albany, Regent's-park; the Camden-road, Goldington-crescent; the Free Hospital, Gray's Inn-road; the Hampstead-road, near Genge-street; the Commissioners' Rooms, Kentish-town, and in Cumberland-market. All this is greatly creditable to the good feeling and good sense of the local authorities of St. Pancras.

ILLUSTRIOUS MEDICAL MEN.—You belong to a profession which has given to classical literature the names of Julius Scaliger and of Thomas Linacre, the protégé of Lorenzo de Medici, the friend of Erasmus, and one of the foremost spirits of his age at the revival of learning. To ethical philosophy and to political science it has given the name of John Locke; to natural history, Hans Sloane, Linnæus, and Blumenbach; to poetry, Akenside and Goldsmith; to comparative anatomy, physiology, and zoology, Hunter and Owen; to chemistry, Black, the discoverer of fixed air and of the doctrine of latent heat; to the fine arts, John and Charles Bell; to natural philosophy and antiquities, Thomas Young, the discoverer of the key to the lost literature of Egypt, the greatest discoverer, after Newton, in the field of optics; to sacred knowledge it has given Haller and Abercrombie, the candid interpreters of those imperishable truths which serve as a beacon-light to man's weary wanderings while on earth, and sustain him with a hope of unceasing rest when his wanderings shall end.—*Dr. Vose.*

Medical Times & Gazette.

SATURDAY, AUGUST 13.

THE MEDICAL REGISTER.

A SERIOUS mistake has been discovered in the Medical Act, which, perhaps, to Medical men may appear quite inexplicable, but by lawyers can easily be understood. The object of that Act, as our readers know, was to enable any person requiring Medical aid to distinguish qualified from unqualified Practitioners; and this the measure proposed to effect by a system of registration. Provision was therefore made for the appointment of registrars, whose duty was to keep their respective registers correct, in accordance with the provisions of the Act and the orders of the General Council. Practitioners possessed of the requisite qualification were declared entitled to be registered; and the Registrar was required to print and publish a correct Register of the names in alphabetical order of all persons appearing on the General Register, as existing on the first day of July in every year; and the Act further declared that such Register (the one printed alphabetically) should be called the "Medical Register," and that a copy thereof for the time being, purporting to be so printed and published, should be evidence in all courts that the persons therein specified were registered according to the provisions of the Act, and that the absence of the name of any person from such copy became evidence, until the contrary should appear, that such person was not registered. Provision was also contained, making a Certificate of Registration, in cases where the name did not appear in the printed Register, evidence. The existing General Register, from whence the names were taken to frame the alphabetical Register, was not declared by the Act itself to be evidence, and, therefore, none but lawyers accustomed to technicalities could divine that it was the duty of the registrars to keep two registers at one and the same time. These duplicate registers, it now turns out, have not been kept. This oversight, if oversight it be, came out in a case we shall at once introduce to our readers. Mr. Henry Scott, of 17, Adam-street, Adelphi, appeared at Bow-street police-office, a few days since, to answer a charge "of representing himself to be a properly qualified Medical Practitioner under the Medical Act, whereas he was not registered under the provisions of that Act." It became requisite, therefore, to show that Mr. Scott was not a duly-qualified Surgeon, and for that purpose a printed copy of the Medical Register was put in, upon which it was objected that the original Register ought to be produced; but this objection the magistrate (Mr. Jardine) overruled, being of opinion that the provisions of the 27th Section of the Medical Act authorised him to receive the printed copy as evidence. It was then shown that the defendant's name was not in the printed copy, and that at his place of business, on the right side of the door-post, there were two bells with metal plates, on one of which was inscribed "Surgeon's," and on the other "House," and that

on the door was a plate with the name, "Mr. Scott," and on the inner-door the name, "Dr. Scott." A witness then proved calling on the defendant on July 27, to consult him, when he said that he was a Surgeon, and that his fee was one guinea, which was paid, and a bottle of medicine given. On this, it was submitted for the defendant, that there was no case established against him to answer, as the evidence of the witness related to what took place on July 27; while the Register was made up to July 1 only. To this it was replied, that if the defendant had registered after that date, the *onus* of proving affirmatively that his name was upon the Register was cast upon him, and not upon the complainant; but the magistrate decided against that construction, and declared that such an interpretation of the Act would be absurd. At this stage of the case the proceedings were adjourned until Friday in last week. During the interval the opinion of Mr. Creasy was taken, who thought the evidence sufficient to convict; but the magistrate considered the question not a matter of law but of common sense,—that Mr. Scott was charged with an offence, alleged to have been committed on the 27th July, the essence of that charge being that his name was not upon the Register, and that to attempt to make out such charge by showing that his name was not on the Register on the 2nd July was insufficient; that, in a criminal proceeding like the present, the *onus probandi* could not be thrown upon the defendant, and that it was for the complainant to prove his case. It was then shown by the clerk to the Medical Council, that he had examined the Register, and found since the 1st July there had been no application for registration by the defendant. On cross-examination, however, this witness stated that, since the 1st July up to the present time, there was no Register kept; that the dockets, or applications for registration, were filed and certificates of registration given, and that at the end of the year the Register would be again published. It was thereupon contended for the complainant, that if the defendant had, in fact, obtained a certificate of registration, it was very easy for him to produce it; but Mr. Jardine declared he could not call upon Mr. Scott to say one word in reply, until the complainant had proved his case against him, and he then asked, "How can a man be registered and receive a certificate that his name was on the Register, when there was no Register in existence? Men of business, (said the magistrate subsequently,) who keep a register, keep a document like that printed book produced, but in manuscript, and the very day after printing it they would again have something in manuscript, where the entries were made from day to day as they occurred. If the Medical Council have not done that they have not acted regularly." It was then stated that the dockets were kept and filed. These were offered to be produced, but they were also rejected; and upon its being remarked that the Act would thus become a dead letter, the worthy magistrate said:—"The Act was quite right; it was an excellent Act; and well calculated to meet the very great evil that unqualified persons were enabled to practise as Medical men. The Act had not, however, been carried out properly by the Medical Council. It was a new law, and the Council were not lawyers; while so long as they do not keep a Register, the Act would be inoperative; not from any defect in itself, but from its not being properly carried into effect. He had no right to assume anything against Mr. Scott, who was entitled to the same fair play as any other person brought before him, and he should therefore dismiss the summons;" which was done accordingly, as there was, in fact, no evidence that Mr. Scott was not a duly-registered Practitioner. This decision has led the Council to the very obvious course of making up the existing General Register by keeping an interleaved Register, from which the certificates of registration can be granted. These will certainly establish affirmatively that the name of

any given individual is upon the Register; but it seems to be a case of omission in the Act where it is desired to prove negatively that any specific name at a particular time, between the making up of one alphabetical Register and another, is not upon the existing General Register, that document is not declared by the Act to be of itself evidence. It is only the printed alphabetical Register; and it is hence to this Register that the declaration in the Act that the absence of the name of any person from such copy shall be sufficient proof until the contrary be made to appear, that such person is not registered, applies. The defect is therefore in the Medical Act itself, not with the General Council or their officers. There ought to have been an express declaration in the late Act, that the existing General Register shall be evidence. Had a Register properly kept even been produced at Bow-street, the legal objection might still have been taken, that such Register was not evidence; that the Act only made the Medical Register and the Certificate evidence; and that although there was a provision for proving affirmatively that a man's name was upon the Register, in the interval between the making up of one Register and another, still no law existed for proving the negative of that proposition. The blame ought not, therefore, to be cast upon the Medical Council or their officials, but on Parliament, for placing upon the statute-book so defective a piece of legislation as the Act in question has proved to be already. One Amendment Act has since been passed to remedy its defects, while another is now in progress; and it is hoped that the next measure introduced to Parliament will be a Bill to repeal its objectionable provisions, and also to enact others more capable of being carried into effect by men unaccustomed to legal technicalities. The Medical Council are not lawyers; but even if they had been we very much doubt whether any one could have foreseen the present difficulty, which must be attributed to the defects of the late Act, and not to any want of zeal or honesty of purpose in the members of the Medical Council, or in those officially appointed to carry out their instructions; although there certainly has been a want of business-like arrangement in the Registration.

An account will be found in another page of the course the Council have taken in consequence of this measure, and of the interview between the Council and a Committee of the Registration Association.

THE WEEK.

MEETINGS of the Medical Council have been held daily at the College of Surgeons since Wednesday week. Copies of the Minutes up to Monday will be found in another column. Our readers will see that a great deal of important business has been already gone through. They will doubtless be better satisfied with the full report we have given than with any summary of our own.

The Medical Acts Amendment Bill has gone up from the Commons to the Lords. As printed—"Brought from the Commons, 9th August"—it admits the registration of Licentiates in Surgery of any University in Ireland; but the clause admitting Midwifery Licentiates was expunged in the Commons. The date January 1, 1861, is substituted for July 1, 1859, in Sections 32, 35, 36, and 37, of the Act, thus extending the period of grace to non-registered persons for eighteen months.

Almost every journal of this Kingdom contains every week the history of a case of death from poisoning which might have been prevented had due care been exercised in the sale of the article which caused the death by the druggist.

Within the last few days we read of the suicide of a gentleman by the aid of nicotine; and we cannot but ask, How and where did he obtain the article? Then, again, a druggist supplies an ignorant girl with cyanide of potassium, for the purpose of removing stains; the girl leaves the solution carelessly exposed, so that a portion of it is swallowed by another person, and death results. How many more deaths does the Legislature require before it will take the druggist question in hand?

Dr. Michell, Member for Bodmin, is about to resign his seat. He has very wisely determined that he will not be torn to pieces, mentally and financially, by the horrors of a Bribery Committee, with which he is threatened. He prefers retiring from his senatorial honours. We were glad to see that his manly reply to Mr. Roebuck's waspish attack was extremely well received by the House.

An enormous waste of bread seems to have been going on in Marylebone Workhouse during past years. An energetic master has suddenly reduced the consumption of bread by some thousand pounds weight a week. When he first commenced operations the consumption was reduced 2200 lbs. in the first week, 2600 lbs. in the second, and 2790 lbs. in the third week. It seems that large quantities of bread went into the wash-tub. It is to be hoped that other workhouses will look after their wash-tubs.

"An Extra-Licentiate of the College of Physicians of London," complained in our last week's Journal, that his position in reference to the College had undergone a most disastrous change. He stated that the College had decreed the making of a *Third Class* class of Licentiates, who were to be allowed to practise pharmacy. We are happy to be able to inform him that the College has not decreed anything of the kind. The College desires to resume the position which it might have occupied in 1815 in relation to the General Practitioner, feeling that it has a high duty to perform. It has consequently made an appeal to the General Council, stating its views to the Council, and requesting the Council to aid it in the endeavour to establish a Joint-Board with the College of Surgeons of England, for the purpose of licensing Practitioners of Medicine and Surgery. We need hardly say that we trust the movement may be successful, for it is one which we have repeatedly advocated; it will rescue, if carried out properly, the General Practitioner from the hands of the Apothecaries' Company, and will place him in a position at once most honourable and natural. A Board constituted of Members of the College of Physicians, and of the College of Surgeons, representing the two branches of our Profession, would necessarily engender a perfect General Practitioner. It would do more towards rescuing the Profession from all contact with trade than any measure which has been heretofore invented for the purpose.

The Judges of our land have, for some strange reason, an inveterate love of irregular Practitioners. Perhaps it is the exclusiveness of the practice of the Law which gives them admiration of such licence in another profession. Mr. Justice Willes has, we find, lately at Shrewsbury, exhibited another example of this kind of legal inclination. A Bone-setter, on bail, comes before him on a charge of manslaughter, and, we need hardly add, was acquitted; the crowd in Court testifying their approbation by the clapping of unwashed hands. We are bound to say that the case (one of compound fracture of the leg) was not shown to have been badly treated—in fact,

if we are to take the Judge's version of the tale as correct, we may conclude that the man did not die from any ill-treatment or neglect on the part of the Bone-setter, but that he died just as patients suffering from compound fractures die in the hands of the most skilful. But the error of the Judge's opinion is wrapped up in the following remarks:—"People in sending for a regular Practitioner had the satisfaction of knowing that he must have gone through a certain course of training; but it did not necessarily follow that because a person had received certain licences and certificates he was the most proper person to cure a fractured limb." We call this neither more nor less than a positive encouragement of quackery. It may be perfectly true that an unlicensed man may be a first-rate Surgeon; but is equally true, that 999 out of every 1000 unlicensed men are very bad Surgeons. Let his Lordship in the place of his words, "*cure a fractured limb*," put "*make a man's will*," and apply the whole sentence to a "Man of Law," and he would readily enough see the fallacy and gross absurdity of his dictum. And surely the absurdity is not greater than in the case he himself suggests. We can only express surprise, that the dust on the legal spectacles of men of such acute intellect should always be so thick when Medicine is concerned before them.

An important memorial has just been presented to the Medical Council by the Council of the Obstetrical Society of London, calling attention to the "generally defective condition of Medical education and examination in the Obstetric department of the Profession." The Medical Council is about to take into consideration the regulations for examination of the different examining bodies. There can be no doubt as to the fact that these regulations require a thorough revision, especially in regard to the regulations to which the memorial refers. A tabular statement is given, from which we select the most prominent facts, and by which the case urged by the memorialists is most fully made out. The Royal College of Physicians requires no certificates of attendance on lectures on midwifery. The production of certificates on this subject at the University of London is optional; and at the Royal College of Surgeons and Apothecaries' Hall certificates of attendance on a "three months'" course of lectures on midwifery only are necessary. On the other hand, long and repeated courses of lectures on Medicine and Surgery are enjoined by the examining bodies—some more, some less. With regard to the clinical study of Midwifery, again, the deficiencies in the present regulations are most obvious and inexplicable. The University of London considers that a candidate for its degree who has attended "six" cases of labour has done all in this way which can be reasonably demanded. The College of Physicians says nothing at all on this subject. The College of Surgeons is equally indifferent in the case of the candidates for the ordinary diploma. The special examination in Midwifery instituted by the College of Surgeons does not meet the difficulty; for Midwifery may be practised by members of the College who have never passed that examination. The Society of Apothecaries enjoins an attendance on twenty cases of labour; and, so far, the regulations of this body stand in strong and laudable contrast with those of the other Metropolitan Examining Boards. With respect to practical instruction in Clinical Midwifery, it does not appear to be considered necessary by any of the Metropolitan Examining Bodies. The Council of the Obstetrical Society reasonably believe that "the interests of the Profession and the welfare of the public demand that the standard of education and examination for those who are engaged in the practice of Midwifery, should be as high in this department as that which obtains in Medicine and Surgery." They "express their deliberate conviction that it is quite impossible to teach the principles of Midwifery in

a single three months' course of lectures." They suggest that the opportunities offered by the various Lying-in Hospitals, the maternity departments of general Hospitals, and other institutions, be more extensively taken advantage of, in affording practical instruction in Midwifery, that the requirements of examining bodies, as regards "Clinical Midwifery," be put more on a par with those relating to Clinical Medicine and Surgery; and last, not least, that in Examinations for Degrees, Diplomas, and Licences, all candidates should, as in the Continental Schools, be tested in Midwifery to the same extent as in Medicine and Surgery. The memorial is signed, on behalf of the Council of the Obstetrical Society, by Sir Charles Locock, the Honorary President, Dr. Rigby, President, and the Honorary Secretaries. The Medical Council will, we trust, give the subject to which it refers its best consideration. The Profession at large is greatly indebted to the Council of the Obstetrical Society for the opportune and able manner in which the subject has been brought forward, and we trust that the Committee to which the Memorial has been referred by the General Medical Council, will support the very reasonable suggestions contained in the Memorial, and so place obstetric education at last on its proper footing.

If the unfortunate dispute which has arisen between the builder and his man should be prolonged for any considerable period, the Hospitals and Dispensaries of our metropolis will infallibly to a greater or less extent, feel its influence. The half-starved wives and pale-faced children of the unpaid mechanic will be seeking for support and nourishment in the shape of steel-wine and cod-liver oil. We cannot, therefore, help feeling a deep interest in this deplorable event. We think that the workman has, *prima facie*, a show of reason in his proceedings. Nine hours of unceasing bodily labour of a fatiguing nature appear to be as much as the human frame ought to be called upon to endure. This side of the question has not been touched upon by any of the masters. Our contemporary, the *Times*, also in arguing it, has totally evaded the consideration of this very material point. The *Times* seems to look upon the mechanic as a thing out of which a given number of hours' labour, representing so much money, may be screwed, at the will and pleasure of the master. Arguments of this kind will not bear the light in these modern days of humanity; everyone feels that there is something defective in calculations which take no account of a man except as a mere piece of mechanism. We should like to hear this question argued fairly. If it can be shown that the human frame cannot, without marked detriment to life, be made to endure more than a given amount of labour, and that more than nine hours' labour materially shortens human existence—then we say that the mechanic has a great show of reason in this matter. We also ought to remember what has been stated by the labourer, that in addition to these hours of actual work, he is, as a rule, compelled to walk an hour's journey to the place of his labour. These are all matters which deserve fair consideration.

THE following, taken from the *Observer*, shows how great men's doings live after them; and is not a bad specimen of the Barnum spirit of the Great Head of the Hygeists:—" [Advertisement.]—'The blood is the life.'—Sir,—We perceive by the *Medical Times and Gazette* of July 23, page 88, the review of a work entitled 'A Treatise on Vital Causes,' by James Newton Heale, M.D., whose leading idea seems to be that the blood is a living fluid! Might we ask how and when this idea was first obtained? for to us it appears to be what James Morison, the hygeist, published upwards of thirty years ago.—We are, Sir, yours, &c., the Members of the British College of Health, Euston-road, London, for the Society of Hygeists, August 1, 1859."

GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

MINUTES OF MEETING, AUGUST 3RD, 1859.

Royal College of Surgeons of England.

Sir BENJAMIN C. BRODIE, Bart., President, took the chair at two o'clock, p.m.

Present—

Sir James Clark, Bart.	Mr. Syme.
Dr. Thomas Watson.	Dr. A. Smith.
Mr. Green.	Dr. Williams.
Mr. Nussey.	Dr. Leet.
Dr. Bond.	Dr. Apjohn.
Dr. Embleton.	Dr. Corrigan.
Dr. Storrar.	Sir Charles Hastings.
Dr. Acland.	Mr. Lawrence.
Dr. Alexander Wood.	Mr. Teale.
Dr. Andrew Wood.	Dr. Christison.
Dr. James Watson.	Dr. Stokes.

Dr. Francis Hawkins, Registrar.

The Minutes of the last meeting of the General Council were read and confirmed.

1. The following Report of the Committee, appointed November 26, to consider the fees for attendances on the General and Branch Councils, was presented. Dr. Stokes, the Chairman of the Committee, stated that Dr. Corrigan dissented from it.

(REPORT.)

"That the rate of payment for attendance on the General Council be the same for all members of the Council.

"That the fees for attendance on the General Council during the first year from the passing of the Medical Act be five guineas per day to each member attending.

"That members of the General Council residing at more than two hundred miles from London, shall receive five guineas per day for the day of their coming, and for the day of their return.

"That the travelling expenses be on the scale formerly approved of by the General Council, and that a guinea a-day be allowed to non-resident members for hotel expenses.

"That the fees for attendance at the meetings of the Executive Committee and Branch Councils be two guineas to each member attending, his travelling expenses being also paid."

Scale of Travelling Expenses.

	£	s.	d.
Scotland	9	9	0
Ireland	8	8	0
Newcastle	6	6	0
Leeds	4	4	0
Worcester	4	4	0
Cambridge	2	2	0
Oxford	2	2	0

Moved by Dr. STOKES, seconded by Dr. ACLAND—That the report be adopted.—Agreed to.

Moved by Dr. ANDREW WOOD, seconded by Dr. WATSON—That the scale of payment for attendance on General Councils, Branch Councils, and Executive Committees, and travelling expenses agreed to by the General Council, be transmitted without delay by the President to the Lords of the Treasury for their approval, in accordance with Section 12 of the Medical Act.—Agreed to.

2. A statement was read from the University of Dublin, relative to the Medical Acts Amendment Bill.

Moved by Dr. ANDREW WOOD, seconded by Mr. Syme—That, in respect that this Council are not in possession of information sufficient to enable them to come to a satisfactory conclusion regarding the papers submitted to them as to the Medical Acts Amendment Bill, the consideration of the question be postponed till Friday next. To be the first business on that day.—Agreed to.

3. A letter was read from the Home Office, enclosing a copy of a letter from a Registered Practitioner, complaining of the high price of the Register, and calling attention to the fact that the Medical Council do not intend to be a prosecuting body.

Moved by Dr. CHRISTISON, seconded by Dr. ALEXANDER

WOOD—That in reference to that part of the letter transmitted by the Home Secretary which complains that this Council "does not intend to be a prosecuting body" for prevention of illegal practice, the Council appoint Dr. Christison, Dr. Alexander Wood, Dr. Corrigan, and Dr. Storrar a Committee, to prepare an answer.—Agreed to.

Moved by Dr. AQUILLA SMITH, seconded by Mr. GREEN—That a Committee be appointed, to report on the cost of the publication of the Register, and the price at which it should be sold.—Agreed to.

The Committee to consist of Dr. Aquilla Smith, Mr. Nassey, and Mr. Green.

4. Moved by Dr. AQUILLA SMITH, seconded by Dr. WATSON—That the General Council shall meet each day at two o'clock p.m. and shall not sit after six p.m.—Agreed to.

3. Moved by Dr. ACLAND, seconded by Dr. WATSON—That a programme of the subject which it is the intention of Members of the Medical Council to bring forward be forthwith prepared by the Registrar, be printed, and distributed to the Members of the Council to-day, and that such a Programme be issued by the Registrar from day to day, as may be required; and that a Committee be appointed, to aid the Registrar, consisting of

Dr. Alexander Wood.	Dr. Embleton.
Dr. Andrew Wood.	Dr. Storrar.
Dr. Aquilla Smith.	

Agreed to.

6. Moved by Dr. CHRISTISON, seconded by Dr. STORRAN—That for the purpose of guiding the Council in coming to a determination, in conformity with Sect. 20 of the Act, respecting the sufficiency or insufficiency of the course of study and examinations of the several bodies whose regulations for their Fellowships, Licences, and Degrees have been communicated to the Council, a Committee be appointed, to prepare a report, laying down a minimum of examinations, and subjects of Examinations, without which no qualification will be held, by the Council (Sect. 20), such as to secure the possession by persons obtaining such qualifications, of the requisite knowledge and skill for the efficient practice of their Profession; and that it be an instruction to the Committee to report on the expediency, or the reverse, of this Council recommending what, in their opinion, would constitute a sufficient course of general and professional education.—Agreed to.

Amendment moved by Dr. CORRIGAN, and seconded by Dr. JAMES WATSON—That a Committee, consisting of be appointed, to examine the returns of education and examination furnished to the General Medical Council, under Clause XVIII. of the Medical Act, and resolution of General Council of November 27, 1858, by the several Universities and Colleges, and to report to the General Council such amendments as may seem to them to be required for the improvement of general and professional education.—The amendment was negatived, and the original motion carried.

7. Moved by Dr. ANDREW WOOD; seconded by Dr. STOKES—That a Committee be appointed, to examine the returns by the different bodies included in Schedule (A), to report in regard to each of these as to how far the course of study and examination required by each is calculated to secure the possession by persons obtaining their respective qualifications of the requisite knowledge and skill for the efficient practice of their Profession; and to report to the Council. As also in regard to the most effective machinery for superintending the examinations, so as to secure that they shall conform to a standard of examinations in general and professional education considered sufficient by the Council.—Agreed to.

It was resolved that the Committee on education, to be appointed in pursuance of the two preceding motions, consist of—

Sir Benjamin C. Brodie, Bt.	Dr. Stokes.
Dr. Acland.	Dr. Williams.
Dr. Christison.	Mr. Teale.
Dr. Andrew Wood.	Dr. Storrar.
Mr. Green.	Sir James Clark.

Dr. Storrar to be Chairman.

8. It was resolved that the Finance Committee should consist of—

Dr. Andrew Wood.	Mr. Nussey.
Mr. Green.	Dr. Bond.
Dr. James Watson.	Dr. Embleton.

Dr. Storrar.

MINUTES OF MEETING, AUGUST 4TH, 1859.

Sir BENJAMIN C. BRODIE, Bart., President, took the chair at two o'clock, p.m.

The same Members were present as on the previous day.

The Minutes of the last meeting were read and confirmed.

The PRESIDENT informed the Council that he had received a letter from Dr. Lawrie, apologising for his absence, on account of severe illness.

1. Moved by Dr. ALEXANDER WOOD, seconded by Mr. Green—That any Medical Practitioner who is entitled to be entered on the Register, by virtue of his connexion with any of the bodies comprehended in Schedule (A), who holds besides a foreign diploma, granted before October 1, 1858, shall be entitled to have these foreign dipomas entered on the Register.

Amendment moved by Dr. STORRAR, seconded by Mr. SYME—That degrees which have been conferred without examination at the seat of a University be not registered.—The amendment was negatived.

2. Dr. ALEXANDER WOOD and Mr. GREEN were allowed to withdraw their original motion and to substitute the following—That all cases of gentlemen applying to register foreign diplomas granted before October 1, 1858, and whose names are entitled to appear on the Register, by virtue of qualifications obtained by examination, be referred to a Committee to examine and to report thereon.

Amendment moved by Dr. CHRISTISON, seconded by Dr. WILLIAMS—That all claims of applicants who possess a foreign degree, not acquired by examination at the University seat, be referred to a Committee for its report and opinion as to the individual claims—Negatived.

The motion, as altered, by consent of the Council (2), was then put, and also negatived.

3. Moved by Dr. THOMAS WATSON, seconded by Dr. AGLAND—That it does not appear to the General Council that a foreign degree, conferred without examination at the seat of the University or College granting the degree, furnishes "sufficient reason for admitting (any person) to be registered."—Agreed to.

4. Letters were read from the India Office, suggesting that the Surgeons and Assistant-Surgeons of Her Majesty's Indian military forces, now serving in India, should not be required to register their names under the Medical Act, and that the General Council should, by special orders, as provided for under the 46th Section of the Act, dispense with the provisions of the 36th Section in the cases of those Medical officers; but that future candidates for admission by competition to the Indian Medical Service, should be required to register their names under the Act.

Moved by Dr. CORRIGAN, seconded by Dr. STOKES—That Lord Stanley's request be acceded to, the exemption, however, not to extend to cases of Medical Officers returning from India to reside in the United Kingdom.

Amendment moved by Mr. SYME, seconded by Dr. ANDREW WOOD—That the Council in their present state of information, cannot see any reason for dispensing with the Registration of Officers in the Indian army.—Agreed to.

5. Dr. ALEXANDER WOOD, as Chairman, presented the following Report from the Committee appointed respecting the complaint that the Council "does not intend to be a prosecuting body."

(REPORT.)

In regard to the complaint made in the letter to the Right Honourable the Secretary of State, relative to the prosecution of irregular practitioners, the committee is aware that exaggerated ideas have been currently entertained in the Medical Profession of the powers and duties of the Council in that respect, and think it right to take advantage of the present opportunity to state what the powers and duties of the Council really are:—

"1. The Council is called on to exclude all irregular practitioners from the Register, and it has exercised the greatest possible care in discharging that part of its duty.

"2. The Council is called on to expunge from the Register the name of any unqualified person who may obtain admission by false pretences. This power has been already exercised.

"3. The Council has the power to expunge from the Register the name of any practitioner who may be found

guilty, in England or Ireland, of a felony or misdemeanour; or, in Scotland, of a crime or offence. One offence of this nature has occurred, but the name of the convicted person having been expunged from the Register for another cause, the Council need not proceed in the matter.

"4. The Council has the power to expunge from the Register the name of any Practitioner whose name may have been struck off from the list of the members of any of the bodies which grant Medical qualifications."

It is no part, however, of the functions of the Council, according to the Act, to institute prosecutions at large for offences against the Act. The committee has also to add, that the funds at the disposal of the Council are quite inadequate for that purpose.

The enforcement of the prohibitory clause of the Act (Sect. 40) is attended with peculiar facilities in Scotland and in Ireland, in each of which divisions of the Kingdom there is a public prosecutor, whose duty it is to relieve all other persons of the responsibility of prosecuting for public offences. In England, this duty unfortunately falls in general on private individuals, or associations, and in this respect offences against the Medical Act are not differently circumstanced from offences at large. The Council will supply any information in its power to those who may become concerned in such prosecutions.—The Report was adopted.

6. Memorials having been read from the Lying-in Hospital in Dublin, and the Coombe Lying-in Hospital, requesting that their certificates should be received as qualifications for registration, it was moved by Dr. STORRAR, and seconded by Mr. LAWRENCE—That in reference to the Memorials of the Governors of the Lying-in Hospital in Dublin, and of the Coombe Lying-in Hospital in Dublin, it is not in the power of the Council to comply with them.—Agreed to.

7. A letter having been read from the Registrar of the King and Queen's College of Physicians, in Ireland, respecting the intended recognition, by the Director-General of the Army Medical Department, of the certificate of the Apothecaries' Hall of Ireland, as a licence to practise Medicine, the consideration of this subject, was postponed, all the documents relative to it not having been received.

8. Moved by Dr. ALEXANDER WOOD, seconded by Dr. JAMES WATSON—That a Committee be appointed to consider special claims for Registration.—Agreed to.

The Committee to consist of—

Dr. Alex. Wood, Chairman.	Dr. Watson (Glasgow).
Sir Charles Hastings.	Dr. Embleton.
Dr. Bond.	Dr. Aquilla Smith.
Mr. Syme.	

Confirmed, B. C. BRODIE.

MINUTES OF MEETING, AUGUST 5, 1859.

Sir BENJAMIN C. BRODIE, Bart. President, took the chair at two o'clock, p.m.

The same Members were present as on the previous day.

The Minutes of the last meeting were read and confirmed.

1. Dr. SMITH presented the following report from the committee, on the "Register":—

"The committee appointed to report on the cost of the publication of the 'Register,' and the price at which it should be sold, have examined the account, which has only just been received from the printer, and find that the amount of it is much lower than the Executive Committee were led to expect, from the estimates which had been laid before them; and that the cost of publication, therefore, will be considerably less than the committee believed it would be when the price at which it should be sold was fixed at 7s. 6d. per copy.

"The committee recommend that the 'Register' should be sold at 4s. per copy; and, as they learn from the Registrar, that about 900 copies have already been sold at 7s. 6d. per copy, they further recommend that to every person who has paid the sum of 7s. 6d., a copy of the next edition of the 'Register' should be furnished gratis."

Moved by Dr. STORRAR, seconded by Dr. ANDREW WOOD—That the report of the committee on the "Register" be adopted.—Agreed to.

2. Moved by Dr. ARJOHN, seconded by Dr. STOKES—That after having maturely considered the case of the Licentiates in Surgery of the University of Dublin, the Council are of

opinion that the curriculum of study, both general and Professional, which they must undergo before obtaining such qualification, is satisfactory. The Council further find that, by what is alleged to be an accidental omission in Schedule (A), of the Act of 1858, such Licentiates cannot legally be placed on the "Register." But, under all the circumstances, they leave it to the wisdom of Parliament to decide whether any, and what relief should be provided for them.

Amendment moved by Mr. SYME, seconded by Mr. LAWRENCE.—The Council having heard the statements of Dr. Apjohn, Dr. Williams, and Dr. Stokes, on their respective sides of the question, relative to the Surgical Licence of Trinity College, Dublin, and the opposition of the Royal College of Surgeons of Ireland, deem it inexpedient to express any opinion on the subjects in dispute. But the Council cannot refrain from expressing their hope that such differences may be speedily arranged.—Votes taken, and Amendment agreed to.

Dr. STOKES was requested to take the chair, which the President had been obliged to vacate.

3. Dr. ALEXANDER WOOD presented the First Report of the Committee on Special Applications for Registration.

"The committee, in giving their report, have to state that their labours have been much lightened by the resolution come to by the Council yesterday, to refuse to register all Medical Degrees obtained without due examination at the seat of the University by which the Degrees are granted. In reporting on all the cases which up to this time they have been enabled to take into consideration, the committee will first bring forward those which are virtually settled by the resolution referred to."

I. DEGREES CONFERRED WITHOUT EXAMINATION.

J. Whitehead, Boulogne-sur-Mer; — Warren; W. J. Pasley Kidd, Glasgow; H. C. Taylor, Glasgow; John Cocker, Bank Hey, near Blackpool; John King, Stroud, Gloucestershire; W. M. Warcup, East Dereham, Norfolk; George Fearon, Edgbaston; R. L. Lobo, 35, Sussex-street, W.C.; Charles Cockerton, Islington; W. C. Bonthron, Craik, Fifeshire; W. A. F. Browne, Dumfries; John Cochrane, Edinburgh; George B. Clark, Cupar Angus; Alexander Currie, Bowmore, Islay; James Edward, Forfar; Thomas Harle, Glasgow; Robert Jefferios, Dalkeith; W. D. McRitchie, Edinburgh; Archibald Mein, Edinburgh; A. M. Adams, Edinburgh; T. M. Alexander, Glasgow; W. A. Roberts, Edinburgh; H. C. Taylor, Glasgow; S. Shortridge, Greenock; J. Watson, Tranent; W. Young, Laurencekirk; A. F. Thomson, Esdaile.

With respect to these gentlemen, the committee have, of course, no alternative but to recommend that their claims be not acceded to.

II. PERSONS APPLYING TO BE REGISTERED WITHOUT ANY QUALIFICATION.

J. C. Chawner, Hanley, Staffordshire; Joseph Webster, Golcar, near Huddersfield; George Dansey, Stoke, Devonport; Francis Bingham, Everton, near Liverpool. The committee recommend that in all these cases the application be refused.

III. LICENCES CONFERRED IN HOLLAND.

1. P. D. Loeterbagh, Lerwick, Scotland. Qualified by examination before the Dordrecht Committee of Medical Education and Superintendence, as City Apothecary, Country Surgeon, and Naval Surgeon.

The Scottish Branch Council have inquired into these qualifications, and approve of them; and the committee, therefore, recommend the Council to allow registration.

2. Solomon Kisch, 85, Duke-street, Liverpool, in similar circumstances. Also recommended for registration.

IV. LICENCES OTHER THAN THOSE UNDER SCHEDULE (A), CONFERRED AFTER EXAMINATION.

1. J. M. Cookesley, Boulogne-sur-Mer. Licence from University of Paris. 2. Frederick Hesse, 4, Carpenter's-buildings, London, E.C. Examined by a Committee of the British Government in Hanover. A Medical Officer in the Hanoverian Legion. Both recommended for registration.

V. CASES OF PERSONS CLAIMING TO HAVE RECEIVED DIPLOMAS FROM UNIVERSITIES WHICH HAVE NOT YET ANSWERED THE REGISTRAR'S CIRCULAR.—John Mackenzie, Gourrock, M.D. of the Academy of Medicine of St. Petersburg; W. Oliver, Laurencekirk, M.D. of Pennsylvania; Henry Dewar, Aberdeen, M.D., Dartmouth College, Hanover,

New Hampshire; Francis Dawson, Rothes, M.D. University, New York. It is recommended that these claims be delayed until the returns be received.

VI. CASE OF A PERSON REQUESTING THE REGISTRATION OF OTHER THAN THE USUAL TITLES.—Dr. Thompson, Yeadon, near Leeds, already registered as M.D., of Giessen, claims to be registered—first, on a Midwifery Diploma of Edinburgh (This is a mere certificate from Dr. W. Campbell, formerly a Lecturer on Midwifery in Edinburgh); secondly, as a Doctor of Surgery, of Giessen; thirdly, as a Doctor of Midwifery, of Giessen. The Committee recommend that these claims be disallowed. The Council approved of the Report, and directed the Registrar to give effect to its recommendations.

4. FINANCE COMMITTEE.—Dr. Smith, Dr. Apjohn, and Sir Charles Hastings, were placed on the Finance Committee, in room of Dr. Andrew Wood, Mr. Green, and Dr. Storrar.—Confirmed, JOSEPH HENRY GREEN.

MINUTES OF MEETING, AUGUST 6TH, 1859.

Mr. GREEN took the chair at two o'clock, p.m.

Present—

Dr. Thomas Watson.	Dr. A. Smith.
Mr. Nussey.	Dr. Williams.
Dr. Acland.	Dr. Leet.
Dr. Bond.	Dr. Apjohn.
Dr. Embleton.	Dr. Corrigan.
Dr. Storrar.	Mr. Lawrence.
Dr. Alexander Wood.	Mr. Teale.
Dr. Andrew Wood.	Dr. Christison.
Dr. James Watson.	Dr. Stokes.
Mr. Syme.	

Dr. Francis Hawkins, Registrar.

The Minutes of the last meeting were read and confirmed.

1. Moved by Dr. CORRIGAN, seconded by Dr. SMITH—That any motion or motions lying over from the previous day take precedence of new matter, except by special permission of the Council.—Votes taken, and motion carried.

2. Moved by Dr. ALEXANDER WOOD, seconded by Dr. ACLAND—That the attention of the Council having been called to the proceedings in the case of Henry Scott, at the Bow-street Police-office, on the 5th inst., as reported in the *Times* newspaper of this morning, they resolve to appoint a committee to consider and report on the whole subject, with power to take the opinion of counsel, if it be considered advisable.—Agreed to.

The committee to consist of:—

Dr. Alexander Wood, Chairman.

Dr. Corrigan.	Dr. Smith.
Dr. Apjohn.	Mr. Nussey.
Dr. Bond.	Dr. James Watson.
Dr. Embleton.	

3. Moved by Dr. ALEXANDER WOOD, seconded by Dr. STORRAR—That the committee appointed to consider and report on the case of the prosecution of Henry Scott, be instructed to receive the deputation of the London Medical Registration Association, which had requested an audience of the Council.—Agreed to.

4. Moved by Dr. STORRAR, seconded by Mr. SYME—That a memorial presented by the Obstetrical Society of London be referred to the Education Committee.—Agreed to.

5. Moved by Dr. ACLAND, seconded by Dr. STORRAR—That the General Medical Council have observed that amendments of the Medical Act have been introduced, at the instance of bodies represented in the Medical Council, into Bills brought into Parliament, without previous communication with the General Medical Council; and that the Council consider it desirable that, in future, such amendments should be first communicated to the President of the Council.—Votes taken, and motion carried.

6. Dr. ALEXANDER WOOD presented the Second Report of the Committee on Special Applications for Registration.

(REPORT.)

I. CLAIMS FOR REGISTRATION OF DEGREES CONFERRED WITHOUT EXAMINATION.—Thomas Royston, M.D. Rostock; Thomas Harle, M.D. Rostock; J. P. Litchfield, M.D. University New York; J. W. Davidson, M.D. Homœopathic College, Cleveland, Ohio. The committee recommend that the foregoing claims be not admitted.

II. CLAIMS FOR REGISTRATION OF DIPLOMAS OBTAINED AFTER EXAMINATION.—Simon Weil, Licence from Berne; Alfred F. Stone, M.D. Medical College, New York; Thomas Cutler, M.D. Louvain; J. C. A. Franz, M.D. Leipsic; L. E. Straube, M.D. Leipsic; W. E. Swaine, M.D. Leipsic; Matthew Truman, M.D. Naples; A. T. Jackson, M.D. McGill College, Montreal; J. D. McDiarmid, M.D. McGill College, Montreal; W. Odell, M.D. McGill College, Montreal; W. Darling, M.D. University New York; C. B. Nankivell, M.D. Pisa. The committee recommend that the foregoing claims be admitted.

III. SPECIAL CASES.—1. Joseph Kahn, M.D. Erlangen after examination.

The committee are not satisfied that Dr. Kahn was "practising as a Physician, in the United Kingdom, before the 1st day of October, 1858;" and therefore recommend that he be not registered.

2. Samuel Eadon, M.D. Western Homœopathic College, Cleveland, Ohio, examined.

The committee pronounce no opinion on this case, but refer it to the General Council.

The report was adopted.

Moved by Mr. SYME, and seconded by Dr. ANEREW WOOD—That the name of Samuel Eadon be not inserted in the Register.—Votes taken and motion carried.

7. Moved by Mr. NUSSEY, seconded by Dr. STORRAR—That a committee be appointed, to consider the future accommodation for meetings of the General Council, and that they be requested to render their opinion on the subject before the termination of the present session of the General Council.—Agreed to.

The committee to consist of

Mr. Nussey, Chairman.

Mr. Lawrence.

Dr. Bond.

Dr. Acland.

Dr. James Watson.

8. The following propositions were read, relative to a proposed co-operation of the Royal Colleges of Physicians and Surgeons of Edinburgh, under Clause 19 of the Medical Act, for the purpose of granting a double qualification in Medicine and Surgery,—agreed to by both colleges, and now submitted, in terms of the said Act, to the General Medical Council for their sanction:—

1. By Clause 19 of the Medical Act, "any two or more of the colleges and bodies mentioned in Schedule (A) may, with the sanction and under the directions of the General Medical Council, unite or co-operate in conducting the examinations for qualifications to be registered under this Act." Hence it is quite competent for a College of Physicians and a College of Surgeons to combine, in order, by a joint examination, to give a double qualification, embracing Medicine and Surgery.

2. Co-operation between a College of Physicians and a College of Surgeons being legal, as stated above, the Colleges of Physicians and Surgeons of Edinburgh propose, with the sanction of the General Medical Council, to make an arrangement for the purpose of granting, by a series of examinations, preliminary and professional, their respective Licences in Medicine and Surgery, so as to constitute a double qualification.

3. It is proposed that the preliminary examinations in Literature and Science, and also the examinations on those professional subjects which are common to Medicine and Surgery, shall be conducted conjointly by a board formed of examiners in equal proportions from the two Colleges.

4. It is proposed that the examinations in Medicine shall be conducted exclusively by examiners from the College of Physicians, and the examinations in Surgery exclusively by examiners from the College of Surgeons.

5. It is proposed that the decision as to the competency of the candidate in all the branches except Medicine and Surgery, shall rest with the conjoined Board of Examiners from the two Colleges; but that the decision as to his competency in Medicine and in Surgery shall rest entirely, in the one case with the examiners from the College of Physicians, in the other case with the examiners from the College of Surgeons.

6. It is proposed that having passed through the final examinations, the candidate shall receive two separate diplomas—one from each College—signed by the Office-bearers of each respectively, so that he may be enabled to produce them to the Registrar under the Medical Act, and

to register two separate qualifications—viz., L.R.C.P.Ed., and L.R.C.S.Ed.

7. The Colleges wish it to be clearly understood, that such co-operation is not to interfere in any degree with the right of each College to grant its diploma separately, as heretofore, to those who may wish a single qualification, or with the right of each College to make similar arrangements with other licensing bodies, if deemed expedient, and if sanctioned by the Medical Council.

8. For the purpose of carrying out the objects stated above, the Colleges have prepared a series of regulations, which they beg now to submit to the Medical Council for their consideration.

Moved by Dr. ALEXANDER WOOD, and seconded by Mr. LAWRENCE,—That the proposed co-operation between the Colleges of Physicians and Surgeons of Edinburgh be approved of.

Amendment moved by Mr. SYME, and seconded by Dr. STORRAR—That the consideration of the proposed union between the Colleges of Physicians and Surgeons of Edinburgh, be delayed, until the questions regarding qualifications for Medical and Surgical practice, which have been submitted to the Council, shall have been decided.

The further consideration of this subject was adjourned.

Confirmed, B. C. BRODIE.

MINUTES OF MEETING AUGUST 8TH, 1859.

Sir BENJAMIN C. BRODIE, Bart., President, took the chair at two o'clock, p.m.

Present—

Dr. Thomas Watson.

Dr. A. Smith.

Mr. Green.

Dr. Williams.

Mr. Nussey.

Dr. Leet.

Dr. Acland.

Dr. Apjohn.

Dr. Bond.

Dr. Corrigan.

Dr. Embleton.

Sir James Clark, Bart.

Dr. Storrar.

Sir Charles Hastings.

Dr. Alexander Wood.

Mr. Lawrence.

Dr. Andrew Wood.

Mr. Teale.

Dr. James Watson.

Dr. Christison.

Mr. Syme.

Dr. Stokes.

Dr. Francis Hawkins, Registrar.

The Minutes of the last meeting were read and confirmed.

Mr. SYME laid before the Council printed copies of the statutes for graduation in the University of Edinburgh, as amended by the University Commissioners.—They were referred to the Education Committee.

1. The adjourned debate on the application from the Colleges of Physicians and Surgeons of Edinburgh was resumed.

Moved by Dr. ALEXANDER WOOD, seconded by Mr. LAWRENCE—That the proposed co-operation between the Colleges of Physicians and Surgeons of Edinburgh be approved of.

Amendment moved by Mr. SYME, seconded by Dr. STORRAR—That the consideration of the proposed union between the Colleges of Physicians and Surgeons of Edinburgh be delayed, until the questions regarding qualifications for Medical and Surgical Practice, which have been submitted to the Council, shall have been decided.—Votes taken; amendment negatived. The motion was then put and carried.

2. The following propositions were read, relative to a proposed co-operation of the Royal College of Physicians of Edinburgh, and of the Faculty of Physicians and Surgeons of Glasgow, under Clause 19 of the Medical Act, for the purpose of granting a double qualification in Medicine and Surgery:—agreed to by both bodies, and now submitted, in terms of the said Act, to the General Medical Council for their sanction:—

1. By Clause 19 of the Medical Act, "any two or more of the Colleges and bodies mentioned in Schedule (A) may, with the sanction and under the directions of the General Medical Council, unite or co-operate in conducting the examinations for qualifications to be registered under this Act." Hence it is quite competent for a College of Physicians and for the Faculty of Physicians and Surgeons of Glasgow (which has powers conferred on it by Royal charter to confer licences in Surgery equivalent to those of a College of Surgeons), to combine, in order, by a joint examination, to give a double qualification, embracing Medicine and Surgery.

2. Co-operation between the two bodies being legal, as

stated above, they propose, with the sanction of the General Medical Council, to make an arrangement for the purpose of granting, by a series of examinations, preliminary and professional, their respective licences in Medicine and Surgery, so as to constitute a double qualification.

3. It is proposed that the examination of all applicants to the Faculty for the licences to be granted by the co-operating bodies shall be conducted in Glasgow.

4. It is proposed that the examiners shall be appointed in equal proportions by the Royal College of Physicians and the Glasgow Faculty.

5. It is proposed that in the examinations the examiners appointed by the Royal College of Physicians shall examine in Medicine, and the examiners appointed by the Faculty in Surgery; but in the preliminary examinations, and in those departments which are common to Medicine and to Surgery, by the conjoined Board.

6. It is proposed that the decision as to the competency of the candidate in all the branches except Medicine and Surgery, shall rest with the conjoined Board of Examiners; but that the decision as to his competency in Medicine and Surgery shall rest entirely, in the one case with the examiners from the College of Physicians, in the other case with the examiners from the Faculty of Glasgow.

7. It is proposed that on approval the candidate shall receive a diploma from each of the bodies, enabling him to register under two separate qualifications—viz. L.R.C.P. Ed., and L.F.P.S.G.

8. It is proposed that the co-operation of the Edinburgh College and the Faculty of Glasgow, shall neither prejudice nor interfere with any legal rights or privileges of either of the contracting parties, nor with the power of either body to grant its diploma separately, as heretofore, to those who may wish a single qualification, nor with their right respectively to unite or co-operate with any other qualified body under the provisions of the Medical Act, and with the sanction of the General Medical Council.

9. For the purpose of carrying out the objects stated above, the College of Physicians and the Faculty have prepared a series of regulations, which they beg now to submit to the Medical Council for their consideration.

Moved by Dr. JAMES WATSON, seconded by Dr. STORRAR.—That the Council now approve of the proposed union between the Royal College of Physicians of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow.—Agreed to.

3. The following letter was read, which had been received from the Poor-law Board:—

“Poor-law Board, Whitehall, S.W.
“5 August, 1859.

“SIR,—I am directed by the Poor-law Board to forward to you, for the information of the General Council of Medical Education and Registration of the United Kingdom, copies of Memorials received by the Board from the Senatus Academicus of the University of Edinburgh, the Council of the Royal College of Physicians of Edinburgh, the President and Council of the Royal College of Surgeons of Edinburgh, the Senate of the University of Glasgow, the Faculty of Physicians and Surgeons of Glasgow, the Principal and Professors of Marischal College and University of Aberdeen, the University and King's College of Aberdeen, the Royal College of Surgeons in Ireland, the Medical Protection Association of the County and City of Cork, the Senate of the University of London.

“The object of these Memorials is to procure an alteration in the provisions of Article 168 of the consolidated general order of the Poor-law Commissioners, whereby the qualification of Medical Poor-law Officers has been settled and fixed.

“According to the terms of that article (a copy of which is enclosed), it will be seen that, although Surgical qualifications are admitted, which depend upon diplomas or degrees conferred by competent authorities in all parts of the United Kingdom, Medical degrees or licences conferred by the Universities and other public bodies in England alone, are deemed essential.

“The exclusion of Scotch and Irish degrees was based upon the consideration that the holders of such degrees had no legal authority to practise Medicine in England; and, therefore, however skilled in their Profession they might be, the Poor-law Commissioners could not legally admit them to an

office which it appeared that they could not discharge without a violation of the law.

“This further principle also, entered into the consideration of the Commissioners, and has since always been kept in view by the Board, namely, that no person should be admitted as a fully qualified Medical officer, whose Diploma or Licence did not afford evidence that he had acquired a competent knowledge of the practice of Medicine or Pharmacy, and also of Surgery.

“The late Statute, 21 and 22 Victoria, cap. 90, sec. 31, enacts, that ‘Every person registered under the Act, shall be entitled, according to his qualification or qualifications, to practise Medicine or Surgery, or Medicine and Surgery, as the case may be, in any part of her Majesty's dominions.’

“Hence, the ground upon which the Poor-law Commissioners mainly acted in reference to the exclusion of Scotch and Irish degrees, appears to have been removed. But the important question still remains, as to what is the exact extent and nature of the qualification which is obtained by the degrees or licences conferred by the several bodies who have made their applications to the Board.

“The Board do not possess any authoritative information on the subject which they can act upon; and they therefore request to be informed by the General Medical Council, how far the Degrees, Diplomas, or Licences, of the several Bodies by whom memorials have been addressed to the Board, confer respectively, the right of practising Medicine or Surgery, or Medicine and Surgery, and are evidence that the persons to whom they are granted have attained a competent knowledge of either, or both, of these branches of the Profession.

“I have the honour to be, Sir,

“Your obedient servant,

(Signed) “W. G. LUMLEY, Assistant Secretary.

“To the Secretary of the General Council of Medical Registration and Education of the United Kingdom, 32, Soho-square, W.”

Extract from the consolidated general order, referred to:—

Art. 168.—No person shall hold the office of Medical Officer, under this order, unless he possess one of the four following qualifications; that is to say:

1. A diploma or degree as Surgeon from a Royal College or University in England, Scotland, or Ireland, together with a degree in Medicine from an University in England, legally authorised to grant such degree, or together, with a diploma or licence of the Royal College of Physicians of London.

2. A diploma or degree as Surgeon from a Royal College or University in England, Scotland, or Ireland, together with a certificate to practise as an Apothecary from the Society of Apothecaries of London.

3. A diploma or degree as Surgeon from a Royal College or University in England, Scotland, or Ireland, such person having been in actual practice as an Apothecary on the 1st of August, 1815.

4. A Warrant or Commission as Surgeon or Assistant-Surgeon in Her Majesty's navy; or as Surgeon or Assistant-Surgeon, or Apothecary, in Her Majesty's army; or as Surgeon, or Assistant-Surgeon, in the Service of the Honourable East India Company; dated previous to the first day of August, 1826.

Moved by Dr. STORRAR, seconded by Dr. CHRISTISON.—That the communication from Her Majesty's Poor-Law Commissioners in England, be referred to a Committee to consider and report upon to the Council; and that a paper from Sir John McNeill, Poor-Law Commissioner for Scotland, laid on the table by Dr. Christison, be referred to the same Committee.—Agreed to.

The Committee to consist of

Dr. Corrigan, Chairman.
Dr. Apjohn.

Dr. Jas. Watson.
Sir Charles Hastings.

4. Moved by Dr. THOMAS WATSON, seconded by Mr. NUSSEY.—That it shall be lawful for the Treasurer of the General Council to contribute, under direction of the Branch Councils, any portion, or the whole, of any money penalty, which may accrue to the Council from a successful prosecution under this Act, towards defraying the expenses of such prosecution.—Agreed to.

5. Moved by Dr. CORRIGAN, seconded by Mr. SYME.—That the General Medical Council is of opinion that any degree or licence, obtained since the passing of the Medical Act, without regular examination by the University or

College granting such degree or Licence, ought not to be placed upon the Register, excepting *ad eundem* degrees, or degrees or licences in Medicine or Surgery of any University in the United Kingdom, admitted to the Fellowships or Licentiateships of the several Colleges of Physicians and Surgeons.

Amendment moved by Dr. ALEXANDER WOOD, seconded by Dr. WILLIAMS—That the General Medical Council is of opinion that for the future, no licence or degree should be given by any of the bodies in Schedule (A) of the Medical Act, without examination.—Votes taken, and amendment carried.

Confirmed, B. C. BRODIE.

THE LONDON MEDICAL REGISTRATION ASSOCIATION.

IMMEDIATELY after Mr. Jardine's decision was given in the case of Henry Scott, an extraordinary meeting of the Committee of the Association was held, the members of which subsequently repaired to the office of the Registrar, in Soho-square, in order to test the accuracy of Mr. Roope's evidence as to the non-existence of a Register. To the astonishment of all it was found that Mr. Roope's statements had been entirely correct, and that no Register, properly so called, actually existed.

The committee next proceeded to the College of Surgeons, where the Medical Council was then sitting, and there made application by letter for a deputation to wait upon the Council relative to the decision of Mr. Jardine. After this the committee went to the House of Commons, and had interviews with several members of Parliament, to urge them to make such inquiries in the House as should lead to the production of a document that should be universally held valid in courts of law on actions being undertaken similar to the one above reported; and Mr. Jardine's decision was on the same night brought under the notice of the House of Commons by Sir Edward Grogan and Mr. Brady. Lord Fermoy, Mr. E. James, Mr. Digby Seymour, Colonel Dunne, Mr. Hennessy, and Mr. Maguire had undertaken to support the views of the Association in the House if any discussion arose.

On Thursday, the 4th instant—the day previous,—in conformity with a vote passed at a general Committee meeting of the Association, Dr. Ladd had written to the Medical Council to request that a time might be named for a deputation to be received by the Council, in order to point out to the latter numerous inaccuracies in the printed copy of the Register. In reply, a letter was received by Dr. Ladd late in the day on Saturday, appointing 12 o'clock on Monday, August 8th, as the time for an interview; and it was then determined by the Committee of the Association, many members of which were hastily convened together, that all the subjects demanding inquiry and discussion should be brought under attention on the same occasion.

Accordingly, on Monday last, at 12 o'clock, the Committee waited upon the Medical Council, at the Royal College of Surgeons. There were present on the part of the Council—Drs. Alexander Wood (in the chair), Bond, Apjohn, Corrigan, Watson (Glasgow), Embleton, A. Smith, Mr. Nussey. The deputation from the Committee of the Association consisted of Mr. Lavies, Vice-President; Mr. Bottomley, Treasurer; Dr. Ladd, Honorary Secretary; Drs. O'Connor, Kirby, and Routh; Messrs. Sutherin, Dansey, C. Clark, and the Assistant-Secretary. The objects of the Association were stated by Dr. O'Connor as being to assist the Registrar under the Act, by affording information to insure correctness of the Register, to prevent illegal practice, and to watch the working of the Act. It had been their duty to bring under the notice of the magistrates at different police courts several cases of illegal practice, and they had done this successfully in all but the last instance. The Association desired to know if it were in contemplation by the Council, in consequence of the decision of Mr. Jardine in the case of Scott, to move the proceedings in a higher court?

In reply to an inquiry from the Chairman whether the present interview was intended to be confined to matters on which one was sought by the application of Thursday previous,

Dr. O'CONNOR explained that the first application—namely,

on Thursday—was made for an opportunity to point out to the Council many defects in the Register as existing; the second appeal for an interview, made on Friday, related to the case of Scott, but that the Association hoped that both subjects would be now considered. Dr. O'Connor instanced numerous examples of errors in the Register.

The CHAIRMAN said that the Association and the Profession must be well aware of the difficulties which had had to be surmounted in the production of the first Register; and he asked that a list of the errors already discovered by the Association might be laid before the Council, promising that they should be amended in the next Register. The Council, he said, had had their attention drawn to the case of Scott immediately on a report of its termination appearing in the newspapers, and that in order to obviate in future any such objections as were made on that occasion, they had already caused copies of the Register to be interleaved (which were shown to the deputation) for the insertion of fresh names as they became registered from day to day, so that a perfect Register to the current time might be always producible. They had also referred the case of Scott to their legal advisers for counsel's opinion as to ulterior proceedings which might be found necessary. The Chairman added, that the Medical Council were sensible of the great advantages which had accrued from the exertions of the London Medical Registration Association, and hoped that the latter would go on with its labours.

Dr. KIRBY spoke of the imperfections which existed in the mode that had been pursued in registering practitioners; and he gave a brief history of the remonstrances that had been made by the Association on this head in the course of last winter, the recommendation of "forms" by them calculated to prove the identity of persons applying to be registered, and the protest which the Association had thought necessary to forward to Sir B. Brodie, the President of the Council. He urged that the mode that had been in force was that which applied to exceptional, and not general applications to register. By the 15th section of the Act, it was necessary to prove the lawful possession of diplomas or licenses; and, by the 16th section, provision was made to carry out the proofs of identity and lawful possession. Dr. Kirby also expressed the general feeling of the Profession that the expense of the Register was much too great. It is a document, he said, which every practitioner would find it necessary to be possessed of, and 7s. 6d. was a large sum to pay annually in addition to his registration fee.

The deputation learned with much satisfaction, in answer to these observations, that the Council, acting on a fresh estimate, had already reduced the price of the Register to 4s. per copy; and they were informed that to compensate for the additional payments that had been made, the purchasers of the copies already sold would each be supplied with a copy of the next Register without charge.

The CHAIRMAN reminded the deputation that every case in which registration had been effected could be re-opened if fraud were suspected; and it would be competent to the Association or any individual to lodge an appeal with the Council for examination into any particular case, which appeal would be sure to receive attention. At the present time, registration had been cancelled in certain instances, and a similar proceeding in some other cases was now under consideration by the Council.

Dr. KIRBY remarked that it was easier and better to prevent persons not legally qualified from getting on the Register than to strike out their names after they had become inserted. He also hoped that a perfect Register would at once be obtained for production in courts of law when necessary, or Practitioners might, as in the late case at Bow-street, again be thrown out of court.

Dr. LADD remarked that the case referred to had been upset by its having been proved on oath that there was, in fact, no Register in existence that could properly be so called. Both speakers were answered that an order had already passed the Medical Council for a manuscript Register to be duly prepared forthwith.

Mr. C. CLARKE earnestly urged the necessity of securing proof of identity before the registration of applicants, and he instanced that there was another practitioner with exactly the same name as his own, and that in similar cases there was no complete security that one person could not make use of the credentials of another.

The CHAIRMAN instanced, in reply, the mode of registration

which had been pursued in Scotland, where a declaration of identity had uniformly been made before a clergyman or a magistrate. The plan as detailed by him met with the unanimous approbation of the deputation, who consider that the same system might with much advantage be extended to England and Wales.

Dr. O'CONNOR called the attention of the Council to the case of John Burton, prosecuted by them at Gloucester, at a charge of £56. His name had improperly obtained admission on the Register, from which it was afterwards expunged; but the Medical Council had refused to undertake the prosecution for fraud upon their Register, and it had devolved upon the London Medical Registration Association to do so at the above considerable cost. He (Dr. O'Connor) wished to be informed if the Medical Council would now bear a portion of the expense which had been thrown upon the Association in this case. He further asked if it were intended to obtain powers in the Bill of Mr. Whiteside, now passing through Parliament, which would enable prosecutions in similar cases to be carried on in the name of the Attorney-General. He was answered that there is no public prosecutor in England, and that in this country an impression existed that prosecutions should rest with individuals who were aggrieved.

The CHAIRMAN, in reply to some observations of Mr. Bottomley, relative to the case of a person named Organ, whose name appears on the Register, said that that case would be gone into the following day.

After some more conversation, the general result arrived at appeared to be, that the attention of the Council had been devoted to the consideration of the various points mentioned in consequence of the representations made to them by letters from the Committee of the Association since the middle of last week. In the case of Scott, especially, the Council, it appeared, had already consulted counsel, and would speedily make a report, to appear on their minutes. The Association were invited to put their views and suggestions in writing, and forward the same to the Council, by whom they would be considered with every attention.

The CHAIRMAN warmly complimented the Association on the zeal and energy which had been displayed by its members; and the feeling appeared to prevail on both sides that great advantage would arise from the interview, and that there is henceforth a prospect of the two bodies working together in complete harmony and co-operation.

PROGRESS OF MEDICAL SCIENCE.

Selections from Foreign Journals.

ON THE EFFECT OF LONG-CONTINUED DOSES OF IODINE.

By M. RILLIET.

M. Rilliet, of Geneva, relates some cases to the Paris Académie in proof that iodine, although administered in small doses, if continued for too long a period, may gradually induce very serious symptoms, the origin of which may not always be obvious. He concludes:—1. The prolonged absorption of an iodised salt, whether contained in water, the air, or in food, is not always without danger. 2. The inhabitants of some localities are more exposed to this influence than others; and such susceptibility may be due to the minute quantity of iodine contained in the air, water, or food, employed in such localities. 3. This iodic intoxication is perhaps more to be feared when the medicine is given in small than in large quantities, as a preventive rather than as a curative agent in a localised and confirmed diathesis. 4. It is a very exceptional occurrence in childhood, rare in adult age, and more to be feared as the subjects advance in life. Therefore the administration of iodine to persons older than forty, must be especially watched, and it must be suspended on the appearance of the first symptoms of saturation, as bulimia, emaciation, palpitation of the heart, or nervous susceptibility. 5. The best remedies in this kind of slow poisoning are milk, restoratives, change of air, and iron.—*Bulletin de l'Académie*, t. xxiv. p. 26.

EXCERPTA MINORA.

Administration of Anæsthetics by Smoking Apparatus.—M. Delabarre, in a communication to the Academy, states that he finds the safest and most agreeable way of administering ether or chloroform, or the two combined, is by a *chibouk*, having a double tube attached, by means of which any quantity of air desired may be admitted. The patient at first smokes air only until accustomed to the action, when the anæsthetic vapour is gradually admitted.—*Bull. de l'Acad.* t. 24, p. 624.

Tannin in Odontalgia.—M. Vellemsseus recommends that the small layer of indurated granular matter deposited through suppuration, should be gently scraped off from the roots of the affected teeth, and the mouth rinsed for some days by an emollient wash in order to dissipate any irritation. When this is subsided the tannin mixture, thus prepared, may be used: tannin 8, alcohol at 86° 120, tincture of benzoin 8, and essence of mint, 2 parts. Dissolve and filter, and add a few drops to the water, used to wash the mouth, two or three times a-day. The wash must be continued some time after the cure seems completed; and under its influence the teeth become firm, suppuration disappears, and the gums resume their healthy condition.—*Gaz. des Hôp.*, No. 88.

Poisonous Effects of Belladonna used externally.—A lady, aged about 43, suffering from severe pain in the hypogastric region, was ordered to apply the following liniment twice a day: Camphorated oil of henbane 30, and extract of belladonna 4 parts. Forty-eight hours after commencing its use she was seized with delirium. The pupils became dilated, and there were irregular movements, lipthymia, redness of the face, and a fixed stare. Sinapisms were applied to the feet, acidulated drinks were administered, and a bleeding was about to be performed, when abundant menstrual discharge came on, anticipating the proper epoch by 10 or 12 days. The symptoms of poisoning gradually disappeared.—*Ibid.* No. 88.

Saline Injections in Diphtheritis.—M. Roche states that he has been so successful in some cases in which he has tried the injection of a solution of chloride of sodium into the throat, that in his next case he is disposed to employ it as the sole means of treatment. He practises, in fact, a continuous, or almost continuous, irrigation of the throat, by means of Eguisier's irrigator, provided with a canula having a very small jet. He believes that it is in such irrigations, whether employing salt, alum, or the chlorates, we should seek for curative agents.—*Union Méd.*, No. 88.

Detection of Pregnancy by Ergot.—A correspondent of the *Boston Journal* states that for many years he has been in the habit of administering small doses of ergot for the purpose of detecting early pregnancy. The specific action of the medicine this was felt by an unimpregnated uterus, while the gravid uterus almost invariably responds to its action by some uneasiness in the back, but more especially in the upper part of the thighs, sufficient to establish the diagnosis. It may be given with entire safety in sufficient quantity to accomplish the object sought.—*Boston Journal*, April, p. 197.

Double Vagina and Os Uteri.—Dr. Stickel, of St. Louis, reports an interesting case in which he found, during an examination, a double vagina and os uteri. The septum dividing the vagina was oblique in direction, in relation to the natural passage—commencing close to the clitoris on the right side, and stretching down to the centre of the labia on the left, forming a perfect partition through the whole length of the vagina; and at the termination of each passage was a perfect os uteri. The patient said she menstruated from each passage alternately, but never from both at the same time; but she did not say whether the alternation was regular. She had borne one child.—*Ibid.* April, p. 208.

Assafetida and Aloes in Ascavides.—Dr. Nathaniel Smith states that during a practice of more than forty years he has never known assafetida and aloes to fail of an immediate cure. He has usually employed the tincture, sometimes clearing out the bowels first by a smart purgative.—*Ibid.* May, p. 287.

DR. WILLIAMS, of the *Alma*, with Major Fane and Captains Cooke and Russell, we read, deserve especial notice for their bold daring in diving and swimming below, handing out ladies and children through the sky-lights when this vessel was wrecked in the Red Sea on a coral reef.

GENERAL CORRESPONDENCE.

EDINBURGH COLLEGE OF PHYSICIANS.—
ADMISSION OF LICENTIATES.
LETTER FROM PROFESSOR LATCOCK.

[To the Editor of the Medical Times and Gazette.]

SIR,—Dr. Haldane's official denial of the accuracy of my statements as to the recent admission of Licentiates into the College of Physicians of Edinburgh needs no notice from me, except a distinct affirmation on my part of the entire accuracy of what I have written. The spirit and manner of that communication I leave to be dealt with by the Fellows of the College generally.

The duty of the Council in regard to the Licentiates in question is plainly set forth in the published regulations (a).

The Council examines and reports to the College on the petitions and testimonials of candidates, their reports being in a tabular form, containing the names, residence, and qualifications of the applicants, and the names of two sponsors or recommenders. These reports are headed, "List of Applicants for the Licence of the Royal College of Physicians of Edinburgh, to be submitted at the meeting of the," and are circulated with the billets summoning the meeting of the College at which the lists are to be balloted for. At the meeting thus called, the Council reports what names should be deleted from the list, stating reasons,—not necessarily of a discreditable character—as, for example, when the name of an applicant is deleted at his own desire. All the ineligible applicants being thus withdrawn from the list, the College proceeds to ballot for the rest *en masse*, and not on "each application," as required by the regulations. The list of applicants thus submitted to the College by the Council on June 14 last, contained 100 names, of whom 97 were balloted for at one ballot, and admitted.

My published analysis is nothing more than an abstract of these official lists, as is clear from my letter. The statement so flatly contradicted by the Council applies to no other applicants than those on the official lists; a fact well known, indeed, to every member of the Council, for no other applicants were or could be known to the College. And I affirm again, that that statement is strictly accurate. Up to August 3 (instant) inclusive, there have been six such lists issued by the Council, containing an aggregate of 235 names of applicants. Three or four of these names, it is true, occur in two lists; but the actual number admitted at six ballots is not less than 210, and the total number withdrawn by the Council is under 20.

What, then, is the meaning of this unqualified denial by the Council of the accuracy of my statement? It is simply a misstatement of the point at issue, and refers, in fact, to other applicants than those on the list. It now appears that the Council have habitually contravened the regulations, and have not reported on "all applicants," as they were bound to do. The lists they sent in were, in fact, selected lists. This circumstance was, however, withheld from the knowledge of the College or the Fellows generally, for several of the latter have assured me that they believed, with me, that the lists sent in by the Council contained the names of all applicants. Now, it is rumoured that among the names thus

(a) I subjoin the regulations as finally agreed to by the College, and which, although repeatedly contravened by the Council, have not yet been duly altered by the College:—

"8. For one year after the passing of these regulations, Licentiates of any of the existing Licensing Boards may be admitted Licentiates of the College without examination, provided that they do not derive any profit from the sale of drugs or medicine, and that they produce certificates of character and Professional qualification satisfactory to the College.

"The following shall be the procedure of the College for the admission of Licentiates under the foregoing regulation:—

"1. The petitions and testimonials of all applicants for the Licence of the College under Regulation 8, shall first be submitted to the Council, and reported on by them to the College.

"2. The names of the applicants so reported, together with a statement of their qualifications, and with the names of those who have certified in their favour, shall be circulated with the billets summoning the Meeting of the College, at which the applications are to be considered.

"3. The petitions of all applicants, as aforesaid, shall be laid before the College, either at a quarterly, or at an extraordinary meeting, along with the testimonials in their favour; and the College shall then proceed to ballot on each application, a majority of two-thirds of those who vote being necessary to declare the applicant duly elected a Licentiate."

improperly withheld by the Council from the knowledge of the College are those of two notorious advertising practitioners. But what a condemnation of the whole system such a rumour implies! If true, it may be equally true, that the applications may be only the work of some wicked wags, but, however arising, the College suffers grievously in reputation by it.

I cannot doubt, whatever may be the Council's notions of "impropriety," that the sympathy of every honest man in the Profession is with those who have resolutely declined to sanction their proceedings in this matter.

I am, &c.

T. LATCOCK.

THE EXPLANATORY MINUTE OF THE
EDINBURGH COLLEGE.

LETTER FROM MR. HUSSEY.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the Minute of Council of the College of Physicians of Edinburgh, lately published, are two passages which need a little more explanation,

"The Council [the Minute says] cannot be surprised that the power of conferring the title of 'Doctor,' should be claimed as an exclusive right by the Universities." The Council perhaps are not aware that the governing bodies of the Universities in England have never put forward such a claim. It is well-known in England, that the Archbishop of Canterbury has the right of conferring degrees as well in Physic as in Divinity, in Arts, in Laws, and in Music; and the right is frequently exercised in all the faculties.

The Council also state that the diploma of the English College of Surgeons "implies legally only a right to perform operations, and attend cases of pure Surgery." The Members of the College will not, I think, acknowledge this to be the only privilege conferred with the diploma. There are, I believe, very few diseases which are not legally within the province of the Members of the College of Surgeons. A long list may be drawn by perusal of the earlier statutes of the realm; among them are intermittent fever, and all contagious diseases; and the Members of the College have always legally had the power of dispensing drugs for the treatment of such diseases.

I am, &c.

Oxford, August, 1859.

E. L. HUSSEY.

THE COUNCIL AND THE REGISTER.

[To the Editor of the Medical Times and Gazette.]

SIR,—Soon after the Medical Act of last year was passed, but prior to nominating the several members of Council by whom that measure must be put into operation, considerable discussion took place among the Profession, whether all the new legislators should be Medical men, or contain likewise some laymen, especially a lawyer, if not gentlemen accustomed to the working out of Acts of Parliament. Although then in a minority, the writer of this communication always advocated the principle to avoid making the Council exclusively Professional; well knowing many important points would come before that tribunal, where legal experience and administrative knowledge might prove exceedingly advantageous, by enabling the Council more easily to arrive at correct decisions. Last year the celebrated Title-column controversy showed the want of some such element as that now mentioned; while the recent investigation at Bow-street respecting an existing Medical Register, indicates how oversights in very essential matters may be committed. During that inquiry Mr. Jardine, the magistrate, said the late Medical Act was an excellent measure, but it had not been carried out properly by the Council; adding, however, by way of apology, "they were not lawyers." Such remarks are most apposite; and fully endorse the critical observations formerly made by those who strongly recommended the Medical Council to embrace within its precincts other parties besides Physicians and Surgeons. The quoted misadventure, and perhaps future *laches* which may supervene, conclusively prove, at all events, the practical advantages which would assuredly accrue, were the above proposition in reference to civilians

adopted. For any one to say that Medical Practitioners are in most instances unaccustomed, or unable properly to administer Acts of Parliament, is no condemnatory reflection; seeing their whole experience and previous studies have been otherwise directed; consequently, it becomes the more necessary they should be assisted in such legislative or executive functions by persons whose minds have been already trained in making laws, and hence are better able to enact judicious regulations for governing the whole Medical Profession, than otherwise inexperienced parties,—more particularly as that body at present comprising numerous grades, and occupying diversified positions, is now entering, as it were, upon a new sphere of existence, fraught, every member fervently wishes, with much future benefit to the public, and free from ultimate injurious consequences.

August 3, 1859. I am, &c. MEDICUS.

PARLIAMENTARY INTELLIGENCE.

HOUSE OF COMMONS.

MEDICAL ACT AMENDMENT BILL.

Mr. WHITESIDE having moved that the House resolve itself into committee on this bill, several hon. members objected to the bill being proceeded with, and eventually

Mr. COWPER moved that the House resolve itself into committee that day three months.

Mr. WHITESIDE opposed the amendment, which was negatived without a division.

The House then went into committee, when

Mr. CRUM-EWING moved that the chairman do report progress, whereupon

The committee divided; the numbers were—

For reporting progress	19
Against	97
Majority	—82

The several clauses were then agreed to, with the exception of the second, which was negatived, and the bill passed through committee.

AUGUST 8TH.

INSPECTOR-GENERAL OF HOSPITALS.

Colonel SYKES asked the Secretary of State for India upon what grounds Deputy Inspector-Generals of Hospitals in the British forces, of less than five years' service, doing duty at home or in the colonies, with the relative army rank of lieutenant-colonel, are to have the local rank of colonel while serving in India from the date of their arrival in that country, agreeably to her Majesty's Warrant of the 1st February, 1859, in supercession of Surgeon Majors and Deputy Inspectors of Hospitals of her Majesty's Indian forces who rank as lieutenant-colonels only, although of twenty to thirty years' service.

Sir C. WOOD said that there were different ranks in the Indian army corresponding with that in the line. In the Indian army there were two classes of Deputy Inspectors of Hospitals, while there was but one in the line. So long as there were the two ranks, some inequality must exist; but it had not been thought desirable to merge the two into one.

MILITARY SURGEONS.

Colonel DUNNE asked the Secretary for War why men who had received the legal right to practise Surgery and Medicine from the Royal College of Surgeons in Ireland were excluded from becoming candidates for Medical appointments in the army; why the Surgeons of cavalry were charged forage-money for their horses, while those of infantry were exempted from that charge; and whether there would be any objection to grant to those deserving Medical officers who had retired from the service the same additional rank which would be given to those who were at present serving on their retirement.

Mr. S. HERBERT replied that, in consequence of the increased pay given to Medical officers, and the increased acquirements expected from them, it had been decided that before admission to the army they should be furnished not only with the diploma of a College of Surgeons, but with a diploma of some other body, as a guarantee of their knowledge of Medicine. He believed that the forage-money of cavalry and infantry Surgeons was regulated by the rules of their respective services. He did not think it would be

prudent to grant additional rank to the Medical officers who had retired. If every new regulation had to be made retrospective it would be impossible to carry out reforms in the army.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, the 4th August:—

CLARK, GEORGE, Newcastle-on-Tyne.
 EVANS, GEORGE MAULE.
 FRESHFIELD, ALLEN, Harwich, Essex.
 HODGSON, JAMES BIRKETT, Preston, Lancashire.
 JAMES, RICHARD, Diffryn, Narberth, Pembroke.
 LEAK, HENRY JOHN BROCK, Jersey.
 LOMAS, HENRY WILLIAM FREER MARTIN, Shildon, Durham.
 MAYON, GEORGE, Mohnmouth.
 MORDUE, ROBERT DIXON, Newcastle-on-Tyne.
 NEWINGTON, ROBERT SAMUEL, Goudhurst, Kent.
 PROVIS, WILLIAM ALEXANDER, Holyhead.
 TORBOCK, ROBSON, Hawes, Bedale, Yorkshire.

The following gentlemen also on the same day passed their First Examination:—

BELEMORE, ALFRED JOHN.
 FARRINGTON, WILLIAM HICKS, Ottery St. Mary, Devonshire.
 FERNIE, HENRY MORTLOCK, Yeldon, Bedfordshire.
 RYLAND, THOMAS EDMUND, Birmingham.
 WARD, HENRY, Diss, Norfolk.
 WORKMAN, CHARLES JOHN, Reading.
 YOUNG, EDWARD PARKER, Henley-on-Thames, Oxon.

APPOINTMENT.

STEAVENSON.—On the 9th instant, Dr. Steavenson was elected Physician to the East Sussex, Hastings, and St. Leonard's Infirmary *vice* Dr. Duke, the founder of the institution, who resigned after eighteen years' service, and was elected Physician Extraordinary.

DEATHS.

AINSWORTH.—Dr. James Ainsworth, Surgeon of the British Hospital at Callao, expired at his residence at Bellavista, on June 13, of ague. He had for upwards of eight years enjoyed a considerable practice, and was deservedly considered the most eminent practitioner then in Peru. After settling in the country, and in conformity to its laws, he passed his professional examination in the Spanish language at Lima, and obtained the diploma, having previously become a member of the Dublin College of Surgeons, and M.D. St. Andrews. He was interred in the British Cemetery near Callao, and his funeral was most numerously attended, showing the high estimation in which he was held, not only by the British and other foreigners, but also by the natives.

BUTTER.—On July 28, Mr. Cornelius Butter, of Ingatestone, suddenly, aged 81. The deceased gentleman had practised upwards of half-a-century in Ingatestone, and was much respected throughout the district.

NORWOOD.—On the 25th July, at Mersham, Edward Norwood, Esq., M.D., in his 70th year. He was formerly Surgeon to the Hertford Infirmary and to Haileybury College; in extensive practice at Thetford, and afterwards at St. Leonards-on-Sea.

STEVENSON.—On the 30th July, at Charlton, William Stevenson, Esq., late Surgeon H.E.I.C.S.

PLINY'S VIEW OF MEDICINE.—"Every disease is either curable or incurable, a man recovers of it, or is killed by it. Both ways physic is to be rejected: if it be deadly it cannot be cured; if it may be helped, it requires no Physician. Nature will expel it of itself."

DRINKING-FOUNTAIN AT OXFORD.—A very novel feature in the drinking-fountain movement has been introduced at Oxford,—namely, the erection of a fountain in the reading-room of the Free Public Library, where it has been in operation several weeks, and has proved eminently successful. The example will, doubtless, be followed by similar institutions throughout the country.

IN the year 1858, 23,704 emigrants returned to the United Kingdom, viz. 18,841 from America, and 4863 from Australia and New Zealand. The large importation from America is doubtless to be accounted for by the great commercial distress prevailing during 1858 in the United States.

NEW DISINFECTING AGENT.—M. Velpeau has laid before the Académie des Sciences some account of the results of the employment of a new disinfecting agent discovered by MM. Demeaux and Corne. Its effect in the removal of the most disgusting odours emanating from wounds, etc. (as gangrene, cancer, etc.) has proved almost instantaneous, while its application is painless and innocuous. It is a cheap greyish powder, exhaling a slight bituminous odour, and is formed of 100 parts of the plaster of commerce in powder, and from 1 to 3 parts of coal-tar. Not only does it possess the power of removing all kinds of stench, but also of absorbing the morbid fluids. For surgical purposes it may be combined with oil, which binds it together without dissolving it. It has been abundantly tried in the wards of La Charité, the dissecting-rooms, and elsewhere, and the most sanguine anticipations are entertained as to the results of the publicity now given, whether regarding it as an application for surgical or hygienic purposes.

A GREAT improvement has of late years taken place in the health of what are called the "Assisted" Emigrants to Australia and New Zealand. From the returns of mortality in the emigration to Victoria for the first nine months of 1858, it appears that the mortality in 127 ships, containing 12,954 souls, was only 79, or .60 per cent. The assisted emigration, amounting to 15,910, was distributed as follows:—New South Wales: males 3277, females 3219; Victoria: males 1734, females 3770; South Australia: males 1863, females 1849; Western Australia: males 41, females 157. The rate of mortality on the whole number is 1.23 per cent. Such a rate of mortality cannot be considered as otherwise than very satisfactory. The healthiness of this emigration is in great measure attributable to the exertions of the Surgeons superintendent of our ships. Second to the Surgeons in maintaining discipline are the matrons appointed over the single women. The appointment of matrons has formed an essential part of our system since our resumption of the conduct of emigration in 1846.

DEATH FROM CHLOROFORM.—We regret to state that another death from chloroform has taken place during the week. The patient was a young man admitted into St. Thomas's Hospital, whose leg it was proposed to submit to amputation last Monday. The most remarkable point in the case is, that the chloroform had been administered to the man in the same manner, some short time previously, for the removal of dead bone, and at that period, though half-an-hour under its effect, he did not seem to suffer, and was thought to bear the anæsthetic very well. The death on Monday was quite sudden, before the man had taken more than half a drachm. The chloroform was administered by the House-Surgeon; and the usual means of resuscitation—"Marshall Hall's method," galvanism, injection of brandy-and-water, etc.—were had recourse to, without appreciable results of any kind. A very careful post-mortem examination was made by Mr. Allingham and Dr. Bristowe, attended by Dr. Kidd, who states that the chief things found were a "dilated state of the right side of the heart, which was gorged with blood, and a curious cyst-like growth, or apoplectic clot, pressing on the middle lobe of the brain, completely obliterating the olfactory nerve and bulb at one side." Probably Dr. Bristowe will furnish a more satisfactory account of what he observed.

TO CORRESPONDENTS.

Scotus.—The letter could not be inserted anonymously.

General Practitioner.—The following gentlemen constitute the Council of the Royal College of Physicians of Edinburgh:—Drs. Alexander Wood, Seller, Charles Bell, Andrew, Fairbairn, W. T. Gairdner, Ziegler,—according to Oliver and Boyd's Almanac.

COMMUNICATIONS have been received from:—

PROFESSOR SIMPSON; Dr. F. HAWKINS; PROFESSOR LAYCOCK; Dr. FRANK, Calcutta; Dr. GRAILY HEWITT; Mr. PITTARD; Dr. BERNAYS; Mr. H. SMITH; Dr. LADD; Mr. HUSSEY, Oxford; Dr. KIDD; Dr. DICKSON, M. VAUDIN, &c. Jersey; Dr. WALLER, Chatham; Mr. LAURENCE; REGISTRAR-GENERAL; Mr. HELY; Mr. WARD; Mr. BOULTON; Mr. FULLER; Mr. RIVERS; Mr. SELF; Dr. ESMARCH, Kiel; Mr. JAMES, Exeter; Dr. PRIESTLEY; Mr. WILLIAMS, Norwich.

APPOINTMENTS FOR THE WEEK.

August 13. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m. King's, 2 p.m.; Charing-Cross, 1 p.m.

15. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.

16. Tuesday.

Operations at Guy's, 1 p.m.; Westminster, 2 p.m.

17. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m. Orthopædic Hospital, 2 p.m.; Middlesex, 1½ p.m.

18. Thursday.

Operations at St. George's, 1 p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.; Great Northern, 2½ p.m.

19. Friday.

Operations, Westminster Ophthalmic, 1½ p.m.

ADDITIONAL TESTIMONY ON THE EXTRAORDINARY EFFICACY OF DR. J. COLLIS BROWNE'S

(M.R.C.S.L., EX-ARMY MEDICAL STAFF)

C H L O R O D Y N E.

(Entered at Stationers' Hall.)

MEDICAL PROPERTIES—Anodyne, Diaphoretic, Sedative, Astringent, Antispasmodic, Diuretic.

From W. R. DAWES, Esq.,
Haddenham.

DEAR SIR,—You should have heard from me sooner respecting the effects of Dr. J. Collis Browne's Chlorodyne, but the fact is, that I have found it so universally applicable as a sedative, that there is great difficulty in making a selection of cases which most strikingly mark its beneficial action without rendering my report inconveniently prolix. I can, however, most truly say, that it is a remedy more generally efficient than any other with which I am acquainted. Its sedative and anodyne effects are not only more speedily produced, but they are also more lasting, and are not followed by exhaustion, or headache, or disturbance of the digestive functions; on the contrary, in many instances its continued use has been followed by exhilaration of spirits and improvement of appetite, especially in the various painful symptoms attending uterine irritation. In hysteria and in dysmenorrhœa, this remedy acts like a charm, as also in nervous headaches and in many cases of cough. In fevers, combined in the early stage with tartarised antimony, it is often of signal service; nor is an increase of dose usually requisite to maintain its beneficial action. In a case of phthisis, the moderate dose of ten minims, taken every night, has sufficed for many months to secure quiet rest, scarcely disturbed by cough, while the omission of it is invariably followed by a restless and coughing night. One fact strikes me as very remarkable—namely, that while the tendency of Chlorodyne to produce constipation is so slight as rarely to require an aperient, it has never failed speedily to stop diarrhoea, or to extinguish attacks of ordinary Cholera. In only two or three instances has it disagreed. The sleep which follows the composing influence of the medicine is peculiarly light and refreshing.

Caution.—Owing to the frequent complaints made by Physicians and General Practitioners of the distress and disappointment caused by the substitution of fraudulent imitations of Dr. J. Collis Browne's Chlorodyne, when prescribed by them for patients, as also vended to them as the genuine (proofs of which are in possession), it is found necessary to adopt the Government Stamp, having the name of Dr. J. Collis Browne's Chlorodyne engraved thereon.

Medical men, Hospitals, and Dispensaries, desirous of obtaining it without stamp, must forward their orders direct, duly authenticated, to the manufactory, when they can be supplied in bulk, a liberal discount being allowed.

Price 3s. per ounce, and in quantity of 10 ounces carriage free.

Sole Agent and Manufacturer—J. T. DAVENPORT, Operative and Pharmaceutical Chemist,
33, GREAT RUSSELL-STREET, BLOOMSBURY-SQUARE, LONDON.

From Dr. J. H. SHORTHOUSE, Carshalton,
Late Physician to the Metropolitan Convalescent Hospital.

I have been in the habit of prescribing Chlorodyne daily for the last twelve months, and beg to express my conviction of its efficiency as a powerful and unique remedial agent. It possesses Anodyne, Astringent, and Anti-spasmodic properties in a remarkable degree.

In all cases of Irritability in which I have tried it, it has induced a state of complete tranquillity and repose. In Phthisis, it has allayed the harassing cough, and diminished the amount of expectoration. In Neuralgia and Rheumatism, it has subdued the pain in a very satisfactory manner. Its effects are totally dissimilar to those of Opium or of any other medicine used in England. In Paroxysmal Coughs from Laryngitis, Croup, Hooping-cough, &c. and in Bronchitis, with copious expectoration, Chlorodyne is superior to any other remedy I am acquainted with. It is also a most efficient Astringent in almost all forms of Hæmorrhage, Hæmoptysis, Hæmaturia, Uterine Hæmorrhage, &c. I have tested its efficacy, and am satisfied with the result. In the case of one gentleman, who, in addition to having a large cavity in the left lung, was also suffering from Diabetes, I prescribed Chlorodyne five months ago; the sugar almost immediately ceased to be passed off by the kidneys, nor has it at any time since appeared in any appreciable quantity, and he may now be considered perfectly well, quoad the Diabetes. The Cough, which before was very troublesome, is now very insignificant. The Hæmoptysis, which had been previously very profuse, has since entirely ceased, and the patient may be considered progressing satisfactorily. He has some knowledge of medicine, and of the effects of different drugs, and he always speaks of his state, after the administration of a dose of Chlorodyne, as a most tranquil and happy one, even when sleep does not follow. He has a perfect intolerance of Opium, and cannot take it in any form or quantity.

DR. DE JONGH'S

(Knight of the Order of Leopold of Belgium)

LIGHT-BROWN COD-LIVER OIL.

CAUTION.

Serious and repeated complaints having been made of a discreditable system pursued by many Chemists and Druggists of intrusively recommending or surreptitiously substituting a pale, yellow, or coarse brown preparation, when Dr. DE JONGH'S Oil is prescribed, the Medical Profession are respectfully and earnestly solicited to afford their assistance in counteracting and repressing a practice alike injurious to their patients and to the fair repute of a remedy now held in such high and general estimation. In all cases where this Oil cannot be procured from a respectable Chemist, application should be made to Dr. DE JONGH'S Agents,

ANSAR, HARFORD, & CO., 77, Strand, London, W.C.

By whom any quantity will be immediately forwarded.

WALTERS' INDIA-RUBBER URINALS.

F. WALTERS having originally invented these Urinals, begs to warn the Profession of the many bad and useless imitations which are now sold, and he would advise them, before purchasing, to look that they are stamped with his name; as, unless that be the case, he cannot guarantee them.

These conveniences are made for those who require them only occasionally, during a long journey, as well as for those invalids who use them always. Mr. WALTERS has much improved them by making them of *Etherised India-Rubber*, which adds very greatly to the strength of the India-Rubber, at the same time that it prevents its sticking together; by this means he is enabled to make them less stiff and harsh than hitherto, and yet to retain all the advantages of that stiffness. There is a patent valve, which prevents the return of the fluid; and they may be worn either sitting, walking, or lying, without the slightest inconvenience, and without being perceived by any one.

WALTERS' CONVENIENCES FOR LADIES will be found particularly useful during pregnancy. They are perfectly soft and flexible, and may be worn with perfect comfort.

All Orders must be accompanied by a Post-office order or reference.—Entrance for Ladies at the private door, where a Female attends.

MANUFACTURER OF ELASTIC STOCKINGS, BELTS, &c.

16, MOORGATE STREET, NEAR THE BANK, LONDON. E.C.

Obstetrical Society of London.—The

next ORDINARY MEETING will be held on WEDNESDAY, Oct. 5, at 8 p.m.; the President, Dr. RIGBY, in the Chair.
The First Session of the Society will terminate in December, up to which time no Entrance Fee will be demanded. The Council beg to intimate their intention of recommending the Society to require the payment of an Entrance Fee of One Guinea, in addition to the Annual Subscription, by Fellows elected subsequently to this date.
Gentlemen desirous of becoming Fellows are requested to apply to one of the Honorary Secretaries.

By order of the Council,
GRAILY HEWITT, } Hon. Secs.
THOS. H. TANNER, }

53, Berners-street.

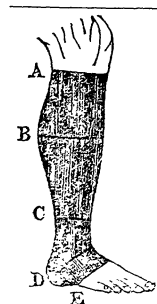

Salop Infirmary.—The Office of House

SURGEON to the above Institution will shortly become VACANT through the resignation of Mr. Dickin. Candidates are requested to declare their intentions of becoming candidates, and to send in their testimonials on or before the 18th day of August instant. No person is eligible for the office unless he be a Licentiate of the Apothecaries' Company in London, and a Member of the College of Surgeons of London, Dublin, or Edinburgh. The salary is £100 per annum, with board, washing, and residence in the Infirmary. Personal canvass of the trustees is not required or wished. By Order of the Weekly Board, Board Room, July 30, 1859. HENRY BEVAN, Secretary.

PELLATT & Co.,
FALCON GLASS WORKS, LONDON.

Health, Fresh Air, and Pure Water.

—By Her Majesty's Letters Patent.—CONDY'S FLUID contains NASCENT OXYGEN, nature's true and only purifying agent; instantly removes all offensive smells; renders impure water fresh, and the air pure; when diluted for use, is of a beautiful colour, not soiling the finest linen; is harmless, and particularly adapted for toilet use, being both refreshing and exhilarating. The Medical Profession have expressed their unqualified approbation of its merits. One gallon makes 200 gallons adapted for use. The cooling, healing, gently stimulating and invigorating properties of this Fluid render it, when diluted, a lotion possessing peculiar and valuable characteristics, whether for bathing the bodies of invalids, incorporating in poultices, or washing and healing wounds. Patronised by the Board of Health, and most public departments, hospitals, schools, and adopted by the India Council in preference to all other disinfectants. In bottles, 6d. 1s. and 2s.; stronger and purer, 1s. 2s. and 4s.

CONDY'S PATENT HEALTH POWDER also contains NASCENT OXYGEN, is odourless, and destroys all smells; in bottles, 1s. 6d. and 3s., and in casks of 1 cwt. 30s.

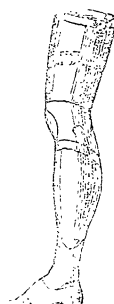

Wholesale agents, John Bell and Co. chemists, No. 333, Oxford-st. W.; Butler and Crisp, 5, Cheapside, St. Paul's.—Chemical works, Battersea, S.W.

N.B.—Orders sent to either Establishment will have prompt attention.

Pratt's Artificial Leg.

J. PRATT begs to call the attention of the Profession to the following Testimonial, just received:—

“Somerset,
June 20th, 1858.

“DEAR SIR,—It affords me much pleasure in being able to state that the Artificial Leg which you supplied me with is far beyond my best anticipations. From its being so LIGHT IN WEIGHT, and its action in the foot so natural, I can walk, or ride on horseback, with ease and comfort; and few indeed would detect it as being other than natural. It has given me full satisfaction.

I am, dear Sir, yours very truly,
J. W.

To Mr. J. Pratt,
Surgical Instrument Maker,
420, Oxford-street.”

WINES FROM SOUTH AFRICA.

Denman, Introducer of the South

AFRICAN PORT, SHERRY, &c. 20s. PER DOZEN, BOTTLES INCLUDED. A PINT SAMPLE OF EACH FOR 24 STAMPS.
Wine in cask forwarded free to any Railway-station in England.
(Extract from the Lancet, July 10, 1858.)

“THE WINES OF SOUTH AFRICA.—We have visited Mr. Denman's stores, selected in all eleven samples of wine, and have subjected them to careful analysis. Our examination has extended to an estimation of their bouquet and flavour, their acidity and sweetness, the amount of wine stone, the strength in alcohol, and particularly to their purity. We have to state, that these wines, though branded to a much less extent than Sherries, are yet, on the average, nearly as strong; that they are pure, wholesome, and perfectly free from adulteration; indeed, considering the low price at which they are sold, their quality is remarkable.”

EXCELSIOR BRANDY, Pale or Brown, 15s. per gallon, or 30s. per dozen. Terms Cash. Country orders must contain a remittance. Cross cheques “Bank of London.” Price Lists, with Dr. Hassall's analysis, forwarded on application.

JAMES L. DENMAN, 65, Fenchurch-st., corner of Railway-place, London.

J. & E. BRADSHAW, late

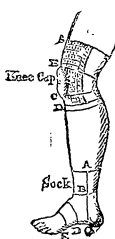

Shoolbred and Bradshaw,

34, JERMYN-STREET,
begs to call attention to the various improvements in Patent ELASTIC STOCKINGS, BELTS, KNEE-CAPS, SOCKS, and Ladies' and Gentlemen's SPINE SUPPORTERS. A new description of BELT, invaluable for prevention of Cholera and the cure of Rheumatism, Lumbago, &c.

N.B. Every description of INDIA-RUBBER BANDAGE, vulcanised on the newest principle.

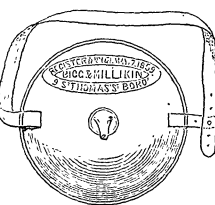

Directions for measurement sent by post.

N.B. A Liberal Discount to the Profession.
A Female to attend on Ladies.

W. Twinberrow begs to draw the

attention of the Medical Profession to his EXTRACT OF INDIAN HEMP, prepared expressly for him at Calcutta, its peculiar sedative properties being so beneficial where opiates are inadmissible. Also to his MEDICINAL EXTRACTS, prepared from the fresh plants (Hyoscyamus Niger, Conium Maculatum, Atropo, Belladonna, Crotalaria Umbellifera, etc.) Also to his Liq. Taraxaci, Liq. Galli Aparinis (a valuable alterative), Liq. Paricariae (diuretic), and Liq. Belce (prepared from the Aglio Marmelos, or Indian Bael), for dysentery and diarrhoea. W. T. has a large supply of INDIAN BAEL on hand. 2, Edwards-street, Portman-square.
BOUDAU'S PEPSINE imported in original bottles. Ed. Lariciis Europ

Registered No. 4171,

May 7th, 1859, by BIGG & MILLIKIN,
9, St. Thomas-street, Borough, MADAME HARRIOT'S MAMMARY FEEDING BOTTLE, or Artificial Breast, by which an infant can receive its food in the most natural position, and be deceived by its pliable and soft texture. It has many advantages that none but a mother can appreciate.—To be had only at BIGG & MILLIKIN'S, Instrument Makers to Guy's and St. Thomas's Hospitals, 9, St. Thomas-street, Borough.

University College, London.—Faculty

OF MEDICINE.—Session 1859-60.—The SESSION will OPEN on Monday the 3rd October, on which day Meetings of the Professors, Students of the Faculty and their friends, will be held at 3 and 8 p.m. The Courses of Lectures, &c. will commence on Tuesday, October 4. Classes, in the order in which Lectures are delivered during the day :—

WINTER TERM.

Anatomy—Professor Ellis.
Anatomy and Physiology—Professor Sharpey, M.D. F.R.S.
Chemistry—Professor Williamson, F.R.S.
Comparative Anatomy—Professor Grant, M.D. F.R.S.
Surgery—Professor Erichsen.
Practical Physiology and Histology—Professor Harley, M.D.
Medicine—Professor Walshe, M.D.
Dental Surgery—Mr. G. A. Ibbetson.
Practical Anatomy—The pupils will be directed in their studies during several hours daily by Professor Ellis, and Mr. William F. Teevan, Demonstrator.

SUMMER TERM.

Materia Medica—Professor Garrod, M.D. F.R.S.
Pathological Anatomy—Professor Jenner, M.D.
Medical Jurisprudence—Professor Harley, M.D.
Practical Chemistry—Professor Williamson, F.R.S.
Midwifery—Professor Murphy, M.D.
Paleozoology—Professor Grant, M.D. F.R.S.
Ophthalmic Medicine and Surgery—Prof. T. Wharton Jones, F.R.S.
Botany—Professor Lindley, Ph.D. F.R.S.
Practical Instruction in operative Surgery—John Marshall, F.R.S.
Analytical Chemistry—Professor Williamson, throughout the session.
Logic, French and German Languages, Natural Philosophy, Geology, and mineralogy, according to announcement of the Faculty of Arts.

CLINICAL INSTRUCTION.

Hospital Practice daily throughout the year.
Physicians—Dr. Walshe, Dr. Parkes, Dr. Garrod, Dr. Jenner.
Obstetric Physician—Dr. Murphy.
Assistant Physician—Dr. Hare.
Surgeons—Mr. Quain, Mr. Erichsen.
Consulting Surgeon to the Eye Infirmary—Mr. Quain, F.R.S.
Ophthalmic Surgeon—Mr. Wharton Jones.
Assistant Surgeons—Mr. Marshall, F.R.S., Mr. Henry Thompson.
Dental Surgeon—Mr. G. A. Ibbetson.
Medical Clinical Lectures by Dr. Walshe, Dr. Garrod, and Dr. Murphy, also by Dr. Parkes, Professor of Clinical Medicine, whose special duty it is to train the pupils in the practical study of disease, and who gives a series of lessons and examinations on the physical phenomena and diagnosis of disease to classes consisting of a limited number, and meeting at separate hours.

Surgical Clinical Lectures, especially by Mr. Quain, and by Mr. Erichsen. Lectures on Ophthalmic Cases by Mr. Wharton Jones.
Practical Instructions in the Application of Bandages and other Surgical Apparatus, by Mr. Marshall.

Practical Pharmacy.—Pupils are instructed in the Hospital Dispensary. Prospectuses may be obtained at the office of the College.
Prizes.—Gold and Silver Medals for excellence in the examinations at the close of the courses in most of the classes.

Liston Gold Medal for Clinical Surgery.
Dr. Fellowes' Medals for Clinical Medicine, two gold and two silver.
Filliter Exhibition for proficiency in Pathological Anatomy, £30.
Longridge Exhibition for general proficiency in Medicine and Surgery, £40.

An Atkinson Morley Surgical Scholarship for the Promotion of the Study of Surgery, £45; tenable for three years.

Residence of Students.—Several of the Professors receive Students to reside with them, and in the office of the College there is kept a register of parties, unconnected with the College, who receive boarders into their families. Among these are several Medical gentlemen. The Register will afford information as to terms and other particulars.

A. W. WILLIAMSON, F.R.S. Dean of the Faculty.
August, 1859. CHAS. C. ATKINSON, Secretary to the Council.
The Lectures to the Classes of the Faculty of Arts will commence on Wednesday, the 12th October.
The Junior School will open on Tuesday, the 20th September.

Lock Hospital.—Separate Establish-

ment for Male Patients.

King's College, London.—Medical

DEPARTMENT.—The WINTER SESSION, 1859-60, will commence on SATURDAY, OCTOBER 1, 1859, on which day all Students are expected to attend the Introductory Lecture, at Two o'clock.

The following Courses of Lectures will be given :—

Anatomy—Professor Richard Partridge, F.R.S.
Physiology; General and Morbid Anatomy—Professor Lionel S. Beale, M.B.
Chemistry—Professor W. A. Miller, M.D. F.R.S.
Principles and Practice of Medicine—Professor George Budd, M.D.
Principles and Practice of Surgery—Professor William Fergusson, F.R.S.

KING'S COLLEGE HOSPITAL.

Physicians... { George Budd, M.D. F.R.S.
R. B. Todd, M.D. F.R.S.
George Johnson, M.D.
W. A. Guy, M.B. F.R.S.
Lionel S. Beale, M.B. F.R.S. } With care of In-Patients.
With care of Out-Patients.
Physician for Diseases of Women and Children and Physician-Accoucheur—Arthur Farre, M.D. F.R.S.
Assistant-Physicians—Charles Murchison, M.D.; Conway Evans, M.B.
Surgeons ... { W. Fergusson, F.R.S.
Richard Partridge, F.R.S.
William Bowman, F.R.S.
Henry Lee, F.R.C.S. ... } With care of In-Patients.
With care of Out-Patients.
Assistant-Surgeons—John Wood, F.R.C.S.; John W. Hulke, F.R.C.S.
Surgeon-Dentist—S. Cartwright, jun.

The Hospital is visited daily. Clinical Lectures are given every week, both by the Physicians and by the Surgeons. The Physicians' Assistants and Clinical Clerks, the House-Surgeons and dressers, are selected by examination from the Students of the Hospital.

SCHOLARSHIPS.—New Students will have the privilege exclusively of contending, in October, 1859, for five Warneford Scholarships—viz., two of £25 per annum, for three years, and three of £25 per annum, for two years. The Examination will commence on the 29th of September, in Divinity, Classics (subjects the same as for the Matriculation Examination this year at the University of London), Mathematics, History, and the Modern Languages.

One Scholarship of £40, tenable for two years; one of £30, for one year; and three of £20 each, for one year, will be filled up in April next, the subjects of the Examination being exclusively Medical.

Further particulars may be obtained from J. Harley, Esq., Sub-Dean of the Department; and a detailed Prospectus will be forwarded by application to J. W. Cunningham, Esq., Secretary.

R. W. JELF, D.D., Principal.

Queen's College, Birmingham.—

FACULTY OF MEDICINE.—The WINTER SESSION will open OCTOBER 3rd, 1859.

Anatomy—Professor Furneaux Jordan, M.R.C.S.
Physiology—Professor Waller, M.D., F.R.S., Physician to the Queen's Hospital.
Surgery—Professor Sands Cox, F.R.S., F.R.C.S., Senior Surgeon to the Queen's Hospital.
Practice of Medicine—Professor W. F. Wade, M.B., B.A., T.C.D., Physician to the General Dispensary.
Chemistry—Professor Bond, M.B., B.A. Lond., F.C.S., Physician to the Queen's Hospital.
Practical Anatomy—Under the superintendence of Professor Jordan and Dr. Walker.

Resident Medical Tutor—T. J. Walker, Esq., M.B. Lond., University Medical Scholar.

Clinical Medicine at the Queen's Hospital by Professors Alexander Fleming, M.D., Augustus Waller, M.D., and Francis Bond, M.B.
Clinical Surgery at the Queen's Hospital by Professors Sands Cox, Langston Parker, J. S. Gamgee, and J. F. West.

The College is situated midway between the Queen's and General Hospitals, and is open to the students of both.

The Junior Department in Medicine is open to students about the age of sixteen, and its studies are specially devoted to preparation for the Preliminary Examinations of the various Universities and Medical Boards, and to the acquisition of a knowledge of the elements of Anatomy, Chemistry, Botany, &c.

The Faculties of Arts, Law, Engineering, Agriculture, and Theology, will also resume at the same period.

For further information and Prospectuses, application may be made to the Honorary Secretary to the Medical Faculty, Dr. Bond, Queen's College.

The Middlesex Hospital. Session

1859-60.—RESIDENT HOSPITAL ASSISTANTS.

For the promotion of Clinical Instruction in the Hospital, the Governors have instituted Three Hospital Assistantships, to be awarded on competition to Students who have completed their education in the School. The Hospital Assistants will reside and board in the Hospital for one year free of expense.

Two House-Surgeons are annually elected by competition from among the Students who have completed their curriculum; they reside and board in the Hospital free of expense. Fee, Twenty Guineas.

Prizes and Certificates are also awarded.
General Fee for all the Lectures, including Practical Chemistry, and for the Hospital Practice required by the College of Surgeons and Apothecaries' Company, £81. This Fee may be paid by instalments.

Further particulars, prospectuses, &c., may be obtained on application to the Dean of the College; to Mr. De Morgan, Honorary Secretary; or to Dr. Corfe, the Resident Apothecary.

T. W. NUNN, Dean.

H. Silverlock's Medical Label Ware-

HOUSE, Letter-Press, Copper-plate, and Lithographic Printing Offices, Wardrobe-terrace, Doctors'-commons, London, E.C.

H. SILVERLOCK'S stock of Labels for Dispensing purposes having been recently revised and enlarged, now consists of upwards of 800 different kinds. Yellow and Green Labels for Drug Bottles, Drawers, &c., at per book or dozen: a Book, containing a selection in general use in Surgeries or Dispensaries, 10s. 6d. Priced Catalogues of the above may be had, post free, on application. Printing of every Description at Moderate Prices.

MEDICAL AGENCY.

NOTICE OF REMOVAL AND CHANGE OF FIRM.

Mr. Lara (for the last eight years the sole representative of LANE and LARA, Medical Agents and Arbitrators and Lunatic Asylum Registrars,) begs to inform the Profession that, in consequence of the daily increasing support with which he has been favoured, and for which he tenders his sincerest thanks and acknowledgments, he has taken into PARTNERSHIP Mr. James Maxfield Walters, a gentleman who has had considerable experience in the business. It will, therefore, from and after Christmas, 1858, be carried on, under the Firm of LARA and WALTERS, at 6, PUMP-COURT, Middle Temple, E.C., whither they have removed their Offices from 22, Buckingham-street, Adelphi, in order to provide that larger accommodation which a constant intercourse with a great majority of the entire body of General Practitioners in England has rendered necessary.

Partnerships and Practices sold and valued: Asylums transferred: Arbitrations effected: Assistants provided (if for a permanence without charge to Employers): and every other description of business transacted for the Profession at a fixed and moderate cost. Attendance from 11 till 4.

St. Thomas's or Guy's Hospital.—

Dr. E. E. BARRON can receive as HOUSE PUPIL, in October next, a FIRST-YEAR'S STUDENT at either of the above Institutions.
15, St. Thomas'-street, Borough, S.E.

Radcliffe Infirmary, Oxford.—Wanted

a DISPENSER to this Institution to enter on his duties on the 23rd of September next. Candidates must send to the Secretary on or before September 6th, satisfactory testimonials of their character and fitness. As-istance is allowed for Dispensing on Out-patient days; but no Laboratory-man is kept. The Salary is £40, with Board, Washing, and Lodging.
August 10, 1859. S. TRASH, Secretary.

General Infirmary, Northampton.—

The Office of one of the SURGEONS to this INFIRMARY having become vacant by the resignation of Henry Terry, Esq. Notice is hereby given, that a SPECIAL COURT of GOVERNORS will be held on SATURDAY, the 1st day of October next, at Twelve o'clock, to ELECT a proper PERSON to fill the said office.

Candidates to be Members of the Royal College of Surgeons of London, Edinburgh, or Dublin.

No Surgeon can be elected who does not engage to have his usual residence in the town of Northampton.

Testimonials and Diploma to be forwarded to the Secretary on or before the 24th day of September next.—By order of the Committee,
August 10, 1859. S. P. BENNETT, Secretary.

Manchester Royal Infirmary and

DISPENSARY. Weekly Board, July 25th, 1859.—WANTED, in consequence of a vacancy about to occur, an Unmarried Gentleman as PHYSICIANS' ASSISTANT to these Charities. Every candidate for the office will be required to produce a diploma from one of the Royal Colleges of Surgeons in London, Edinburgh, or Dublin, and be a Licentiate of the Worshipful Society of Apothecaries, London, or he shall be a Graduate of Medicine of the London University. The gentleman who may be elected will be required to remain in the situation for a term of not less than two years, to reside in the house, and devote the whole of his time to the duties of the office; which duties consist in visiting and prescribing for the home and out patients. Salary, 60 guineas a year, with board and lodging. Letters from candidates, with their diplomas and other testimonials, must be sent (free of charge) on or before Saturday, the 20th August next to the Secretary, at the Royal Infirmary.—By order of the Board,
ROBT. THORPE RADFORD, Secretary.

Addenbrooke's Hospital, in the Town

of CAMBRIDGE.—HOUSE APOTHECARY.—NOTICE IS HEREBY GIVEN, that a SPECIAL GENERAL COURT of the PRESIDENT and GOVERNORS of the above Institution, will be held in the Board-Room of the said Hospital, at Eleven o'clock in the forenoon of the 5th SEPTEMBER next, for the ELECTION of a GENTLEMAN, to fill the office of House Apothecary, vacant by the resignation of Mr. Edmund Carver. The Gentleman elected will have to reside, and will be boarded the Institution. The Salary is £86 a-year.

All Candidates must be duly qualified, and must forward Testimonials as to ability and character, sealed up, under cover, to the Secretary, before the 31st of August, and must produce their qualifications to the Court, on the day of Election.

And notice is hereby further given, that in case of a contest, votes will be received by the Court, at the Board-Room, from 12 o'clock at noon, until 5.30 o'clock in the afternoon of the said fifth day of September, when the Election will finally close.

Ladies only can vote by proxy, forms of which, and all particulars, may be had upon application, at the office of the Secretary.

By Rule 24 no Governor can be allowed to vote whose Subscription is unpaid; nor unless he has been a Governor for six months, except he be a benefactor of Twenty Guineas and upwards.

Annual Subscriptions became due on the 29th of September last, and as Subscriptions are paid in advance for the current year, all Governors by yearly subscription of two guineas must pay their Subscriptions up to the 29th September, 1859, together with all arrears, if any, to EDMUND JOHN MONTLOCK, Esquire, Banker, Cambridge, the Treasurer, before their votes can be received.

By order,
FREDERIC BARLOW, Secretary.

St. Andrew's-street, June 30th, 1859.

Wanted, an In-door Assistant to a

SURGEON in General Practice, to Visit, Dispense, and attend Midwifery. Apply to R. Y. Ackerley, 6, Prince Edwin-street, Liverpool.

Medical Transfer and Partnership.

30, Bucklersbury, Cheapside.

Mr. Orridge, Medical Transfer Agent,

Referee, and Valuer of Medical Property, may be consulted, at the above Address, by Gentlemen about to receive PARTNERS, or to RELINQUISH or to COMMENCE Practice.

Mr. Orridge is known to many of the Hospital Physicians and Surgeons of London.

He has been concerned professionally for a considerable proportion of the most influential Practitioners (including Partners in many of the leading Medical Firms), to whom he has the satisfaction of being permitted to refer—a privilege that he trusts will be regarded as a proof of the sincerity of his endeavours to conduct these transactions in an honourable and straightforward manner.

Gentlemen desirous of obtaining Mr. Orridge's opinion, or requiring his attendance professionally in any part of England, can obtain terms on application, by (confidentially) transmitting name and address.

Office Hours, from Eleven to Four.

Northampton General Lunatic Asylum.

—HOUSE-SURGEON WANTED.—NOTICE is hereby given, that a SPECIAL COURT of DIRECTORS of the above Institution will be held on WEDNESDAY, the 31st day of AUGUST next, at One o'clock, to APPOINT a HOUSE-SURGEON. Candidates to be Members of the Royal College of Surgeons of England, and Licentiates of the Apothecaries' Company of London; also, not more than 25 years of age, and unmarried. Salary, £100 per annum, with apartments, board, and washing.

Testimonials and Diplomas to be forwarded to the Secretary, on or before the 22nd day of August next.

By order of the Quarterly Court,

The Asylum, July 29, 1859.

JOHN GODFREY, Secretary.

Eastern Dispensary of Bath.—The

Vacancy previously advertised for not having been filled up, a RESIDENT MEDICAL OFFICER is required, who must possess the Diploma of a Royal College of Surgeons and Society of Apothecaries. The salary is £80 per annum (rising to £100 per annum with length of service), together with furnished apartments, coals, gas, and domestic attendance.

The Election lies with the Governors and Subscribers entitled to vote, and is appointed to take place on the 8th day of SEPTEMBER next. A preference (ceteris paribus) will be given to such Candidates as will undertake to continue in the Office for a period of at least two years.

The Candidate elected will be required to enter upon his duties on the 25th day of September.

Testimonials (post paid, and marked "Eastern Dispensary," to be forwarded, on or before the 27th instant, to E. Turner Payne, Esq., Honorary Secretary, 5, Old King-street, Queen-square, Bath, who will afford any further information required.

Bath, 4th August, 1859.

Wanted, an Assistant, to Dispense,

and qualified to undertake the treatment of minor cases in the absence of the Advertiser. One accustomed to Union and Club Practice preferred. Address (stating salary required, and giving reference to last employer) to W. X., care of Messrs. Gale, Baker, and Co., Bouverie-street, Fleet-street, London, E.C.

Practice for Sale, in a populous Village

on the EASTERN COAST, close to a Railway Station. Average Income, nearly £300 per annum, £100 of which is from Appointments. A married man with the double qualification would find this an eligible opportunity. Satisfactory reasons will be given for its disposal. Particulars of Messrs. Wright and Co., 11, Old Fish-street, City.

To Parents and Guardians.—A Married

Medical Man, residing close to Guy's and St. Thomas's Hospitals, will have VACANCIES, in October next, for ONE or TWO HOSPITAL PUPILS to reside with him. Every advantage afforded for study, and every domestic comfort guaranteed. Terms moderate. Apply by letter, or personally, to M.D., 12, Wellington-street, London-bridge, S.E.

In-door Assistant Wanted, in a

Provincial Town. A Gentleman possessing the Double Qualification, and duly registered, will be required to assist in Dispensing. Salary, £80 per annum. The most satisfactory references required. Address, Messrs. CORBYN & Co., 300, Holborn, London.

To the Medical Profession and Others.

—Any person possessing the Visiting-Books or Account-Books of London Physicians, Accouchers or Medical Men practising in 1762, in the then fashionable district of Soho-square, is earnestly requested to communicate with Mr. Edward Walmisley, Solicitor, 25, Abingdon-street, Westminster, S.W.

Immediate.—A Gentleman, who, owing

to the delicate health of a member of his family, is compelled to reside in the Country or near the Sea, wishes to TRANSFER immediately, a small but most respectable CONNEXION in an important town in the North-Western district. A short introduction will be given, but the transfer guaranteed to a well-qualified Gentleman. As the Advertiser is anxious to move as soon as possible, no reasonable offer will be refused, or an equitable Exchange of Practices might be effected. Address, M.B., care of Mr. Bowmer, M.R.C.S., 5, Lincoln's-inn-fields, W.C.

London: Printed by CHARLES REED and BENJAMIN PARDON of 1, 2, and 3, Lovell's-court, Paternoster-row, in the City of London, and published by JOHN CHURCHILL, at the Publishing Office, No. 11, New Burlington-street, in the Parish of St. James, in the City of Westminster.—August 13, 1859.

VOL. XL. No. 1038.—NEW SERIES, No. 477.

Just published, 8vo, cloth, with Plates, 15s.

On the Organs of Vision: their

Anatomy and Physiology. By THOMAS NUNNELEY, F.R.C.S.E., Lecturer on Surgery in the Leeds School of Medicine; Senior Surgeon to the Leeds General Eye and Ear Infirmary.

"We cannot conclude this necessarily brief and imperfect Notice of Mr. Nunneley's book without again expressing our decided opinion of the talent and research which pervade it. Many abstruse and difficult points are treated in a masterly manner; the plates, some of which are coloured, are very accurate and beautiful; and the entire subject of the Anatomy and Physiology of the Organs of Vision is brought before the Profession with a clearness and completeness for which we shall in vain seek a parallel either in this country or on the Continent."—The Lancet.

John Churchill, New Burlington-street.

NEW EDITION OF SKEY'S OPERATIVE SURGERY.

In crown 8vo, with many Woodcuts, price 12s. 6d. cloth,

The Principles and Practice of OPERATIVE SURGERY. By FREDERIC C. SKEY, F.R.S., Member of the Council of the Court of Examiners of the Royal College of Surgeons of England, Surgeon to St. Bartholomew's Hospital, &c. &c. Second Edition, revised and enlarged.

"We accept it as the candid record of the experience of one of the foremost amongst us—as the work of a man who has thought deeply and independently, and has honestly endeavoured to make the knife—what, indeed, it ever should be—the last resource of the Surgeon."—The Lancet.
"The independence of thought and research which characterises it gives it a peculiar merit, and justifies our recommending it to every earnest student of his profession."—British and Foreign Medical Review.

"There is much sound and wholesome doctrine in Mr. Skey's work—his reputation as a good Surgeon cannot fail to be advanced by it."—Medical Times and Gazette.

"We are glad to see this Second Edition, and can honestly recommend it as an invaluable guide to operative practice."—Medical Circular.

London: Longmans, Brown, Green, and Longman.

A Perusal of all the New Books
as soon as published, for
ONE GUINEA PER ANNUM.

LEWIS'S MEDICAL LIBRARY, 15, GOWER STREET NORTH.
